## PREFACE TO THE SECOND EDITION.

THE New and Revised Edition now issued contains such corrections and additions as the stereotyped text of the First Edition permitted to be made. The Editor takes the present opportunity to thank the many kind friends who have given him their valuable aid in pointing out errors and omissions, and in supplying the necessary corrections. His thanks are especially due to the Rev. M. J. Berkeley [M. J. B.], Dr. Masters [M. T. M.], Professor Thisleton Dyer [W. T. D.], Colonel J. G. Halliday [J. G. H.], Mr. James Britten [J. Br.], and Mr. J. R. Jackson [J. R. J.], who have not only supplied emendations of the original text, but have also contributed copiously to the Supplemental matter which has been introduced, and which, as nearly as possible, brings the TREASURY OF BOTANY up to the present date in respect to its information.

T. M.

BOTANIC GARDEN, CHELSEA :  
*November 1873.*

## LIST OF PLATES.

I. EPIPHYTAL RHODODENDRONS OF THE HIMALAYA . . .	<i>Frontispiece</i>
II. VEGETATION OF THE CAROLINE ISLANDS, ON THE OUT- SKIRTS OF WOOD . . . . .	<i>To face page 190</i>
III. ANTIARIS AND COFFEE PLANTATION IN JAVA . . .	74
IV. VEGETATION OF BAMBOOS IN JAVA . . . . .	120
V. VEGETATION OF NEW SOUTH WALES, NEAR PORT JACKSON . . .	1239
VI. FOREST ON GUAHAN, ONE OF THE MARIANNE ISLANDS . . .	368
VII. CORAL REEF IN THE CAROLINES . . . . .	1157
VIII. VEGETATION OF TENERIFFE, WITH SUCCULENT EUPHORBIAS . . .	470
IX. VEGETATION OF JAVA—TREE-FERNS IN THE FOREGROUND, A FOREST OF AMENTACEÆ IN THE DISTANCE . . .	494
X. SWAMPY FOREST, WITH BANYAN TREES, IN THE ISLAND OF UALAN . . . . .	1139
XI. VEGETATION OF THE CANARY ISLANDS—VILW IN THE CALDERA . . . . .	89
XII. VEGETATION OF THE CINCHONA FORESTS OF PERU, WITH PALMS AND TREE-FERNS . . . . .	281
XIII. VEGETATION OF JAVA . . . . .	840
XIV. MOUNTAIN VEGETATION OF JAVA . . . . .	956
XV. VEGETATION OF NEW HOLLAND—AN ACACIA 'SCRUB' . . .	5
XVI. VEGETATION OF KAMTSCHATKA, WITH TALL UMBELLI- FERS—A BIRCH FOREST IN THE DISTANCE . . .	1189
XVII. CACTUS VEGETATION ON THE BANKS OF THE GILA, NEW MEXICO . . . . .	236
XVIII. HYPHÆNE OR DOUM PALM-TREES IN UPPER EGYPT . . .	612
XIX. VEGETATION ON THE ICE-CLIFFS IN KOTZEBUE SOUND, ARCTIC AMERICA . . . . .	1026
XX. HOLY CROSS ABBEY, COVERED WITH IVY . . . . .	572

## ILLUSTRATIONS OF PHYTO-GEOGRAPHY.

THE PLATES of which the following pages furnish explanations, have been prepared with the view of showing some of the more remarkable aspects of the vegetation which clothes the surface of the earth in different parts of our planet. From these examples, which have been selected from a variety of sources, a tolerably adequate notion may be formed of the nature of the luxuriant and diversified leafage to be met with in tropical forests; while some knowledge may also be obtained of the quaint succulent vegetation which is scattered over the rocky arid wastes of the New World; of the scarcely more abundant, and much less developed, clothing to be found on arctic cliffs; of the peculiar tree-growth of the Australian continent; and of the characteristics of various other well-marked centres of plant life, the peculiar features of which are pointed out in the descriptive notice of each Plate.

### EPIPHYTAL RHODODENDRONS OF THE HIMALAYA.

(Plate I.—*Frontispiece*.)

[REFERENCE.—*Rhododendron Dalhousiae*]

THE focus of the genus *Rhododendron* seems to be East Nepal and the Sikkim Himalaya mountains. It is there we find the species most numerous and their flowers of the greatest size and most brilliant tints. The genus chiefly prevails between 10,000 and 14,000 feet above the sea-level, its several species composing three-fourths of the vegetation above the forest region (12,000 feet). There *Rhododendron* wood supplies the native with fuel, and, from its tough nature and property of being easily worked, with many domestic utensils, poles for his tent, stools, saddie, bowl and spoon. The bark is used as that of the birch in the Arctic regions, and the leaves serve as plates and wrappers for butter, curd, and cheese. It is the traveller's constant companion throughout every day's march; on the

right hand and on the left hand of the devious path, the old trees and bushes are seen breast high or branching overhead, whilst the seedlings cover every mossy bank. At 13,000 feet the flanks of the snowy mountains glow with the blood-red blossoms of *Rhododendron fulgens*, whilst the beauty of *R. campanulatum* and the great elegance and delicacy of the white bells of *R. campylocarpum* excite the more admiration from their being found in such regions of fog and rain. Some kinds grow habitually as epiphytes, among them *R. Dalhousiae* figured in our frontispiece, and one of the many noble introductions for which we are indebted to the labours of the indefatigable Dr. J. D. Hooker. *R. Dalhousiae* is a slender straggling shrub, six to eight feet high, with oblong leaves, and white bell-shaped fragrant flowers with a delicate rosy tinge. It is generally growing, like many tropical orchids, amongst moss, with ferns and *Aroidæ*, upon the limbs of large trees, at from 5,000 to 9,000 feet above the sea, in a region of fogs, moisture, and rain, in sight of the snow-capped peaks of the Himalaya. [B. S.]

# VEGETATION OF THE CAROLINE ISLANDS, ON THE OUTSKIRTS OF WOOD.

(Plate II., p. 190.)

[REFERENCE.—a. *Artocarpus incisa*; b. *Caladium*; c. *Pandanus odoratissimus* in fruit; d. *Crinum*; e. Tree-Fern.]

This illustration introduces us into a valley of the island of Ualan, Caroline Archipelago, where, without much labour, the level land has been brought into a certain state of cultivation, being planted principally with those products of the island which furnish food. Bread-fruit trees, bananas, two gigantic species of *Caladium*, and the Tahitian sugar-cane grow here so intermingled that there is some difficulty in determining whether there has been any arbitrary plantation or not. The Bread-fruit tree (*Artocarpus incisa*) on the left-hand side is quite a young specimen, just beginning to bear fruit. The plantains and bananas of this place belong to four varieties, the specific types of which are *Musa paradisiaca* and *Musa sapientum*. Of the two larger *Caladiums* (fig. b) one is allied to, if not identical with, the well-known *C. macrorrhizum*, the root of which is used as an article of food. A third smaller species is the *Caladium esculentum*, the Kalo or Taro of the South Sea Islands. *Pandanus odoratissimus*, the Screw-plum, so called from its leaves being arranged like the windings of a screw, and its fruits having somewhat the outward appearance of pine-cones, is seen on the right-hand side of our illustration. Close to it will be seen the *Morinda citrifolia*, having a pale-green foliage and a whitish edible fruit of poor flavour. To the most prominent plants of this island belongs the widely-diffused *Dracena terminalis*, commonly used for hedges. A fine *Crinum* with massive leaves grows isolated about the outskirts of the forests; and a *Marrubium*, growing gregariously, abounds. Almost in the very centre of our picture are seen tree-ferns; and just above them the *Terminalia Catappa*, the horizontal branches of which form distinctly marked stories around the erect stems, imparting to the tree the aspect of a pine tree, and to the landscape a very peculiar and well-marked feature. [B. S.]

# ANTIARIS AND COFFEE PLANTATION IN JAVA.

(Plate III., p. 74.)

A glance at our illustration, taken from Ruine's magnificent *Rumphia*, showing the *Antiaris toxicaria* or Upas tree of Java, surrounded by coffee plantations and other indications of human industry, at once disproves many of the exaggerated and

'fabulous accounts propagated about this famous poison plant by the early travellers. There is no sign of the extreme sterility of the ground in the vicinity of the poison trees, which was said for a considerable distance round to produce neither grass nor any other vegetable. Nor can it, with such surroundings, be true that, if the tree be pierced, those standing to windward would quickly be suffocated by its noxious effluvia, or that birds which fly over a recently wounded tree would meet the same fate. These and similar fables, Bennett and others have explained by transferring the odium to the maraby and unwholesome exhalations of parts of the Indian Archipelago to which state criminals, and especially those of the highest class, were sometimes banished, and where they speedily died of malarial, and not, as the vulgar believed, of the emanations of the Upas tree. The poisonous nature of the *Antiaris toxicaria*, stripped of all exaggeration, is, however, sufficiently powerful and deadly to make great precaution necessary. Dr. Horsfield had some difficulty in inducing the inhabitants of Java to assist him in collecting the juice which he required for his experiments, as they feared a cutaneous eruption and inflammation, resembling, according to the account they gave of it, that produced by the *Rhus vernix* of Japan, and the *Rhus radicans* of North America; but they were only affected by a slight heat and itching of the eyes. In clearing new grounds for cultivation, in which the Upas tree occurs, it is with difficulty the inhabitants can be made to approach the Upas, as they dread the cutaneous eruption which it is known to produce when newly cut down. But except when the tree is largely wounded, or when it is felled, by which a considerable portion of the juice is disengaged, the effluvia of which, mixing with the atmosphere, affect persons exposed to it with the symptoms just mentioned, the tree may be approached and ascended like the other common trees of the forests. [B. S.]

# VEGETATION OF BAMBOOS IN JAVA.

(Plate IV., p. 120.)

Those who compare the small meadow grasses of northern countries with the tall cocoa-nut trees of the tropics will probably think it fanciful that botanists should proclaim the piebald grasses to approach in their external structure, as well as their internal organisation, nearest to the palms, termed by the illustrious Linnæus, the Princes of the Vegetable Kingdom. But this dictum of science will appear less fanciful when the huge bamboo, as the noblest representative of the grasses, with its tree-like trunk fit for fuel and building

purposes, and its light feathery foliage, is placed by the side of some small rattan as the representative of the palms. Indeed grasses are regarded by many eminent botanists as a sort of palm of lower grade. In-habit the two natural orders have much in common: their leaves are formed upon exactly the same plan, the only difference being that those of the palms are generally (not always) divided. Even the siliceous secretions so characteristic of grasses, are observable in rattans; whilst about their flowers, it may be said that those of the grasses are those of the palms, with the floral envelopes removed and only the bracts remaining. The group on the right-hand side of our plate affords a good illustration of the manner in which bamboos grow. They delight in humid localities, and are the ornament of most tropical rivers, often forming impenetrable thickets, the favourite retreat of wild animals. Their young shoots come up like asparagus, and in many Eastern countries are picked and preserved. The growth of the stem is rapid in the extreme. *Dambusa gigantea* was found to grow 25 feet 8 inches in length during the thirty-one days of July, 1833, when it was measured in the Calcutta Botanic Garden; and in the Botanic Garden at Glasgow the same plant was ascertained to rise one foot in twenty-four hours: so that an attentive observer could actually see a bamboo grow as plainly as he could see the movements of the hands of a watch. [B. 8.]

#### VEGETATION OF NEW SOUTH WALES, NEAR PORT JACKSON.

(Plate V., p. 1239.)

[REFERENCE.—a. *Banksia*; b. *Xanthorrhoea*.]

The view here presented is that of Port Jackson as it was when the illustrious Bauer visited it, rather than as it is at the present day, when Sydney has become a large magnificent city, and its wealthy inhabitants have scattered elegant villas and country-seats all over the neighbourhood, when thousands of *Araucarias* have been planted to give variety to the monotony of the Australian vegetation, and when foreign trees, shrubs, and weeds are as fast taking the place of native productions as the white race has usurped that of the black. Yet there is still a great deal of the original vegetation left. Even in Sydney itself, much that is seen in the parks and gardens consists of gum trees and other *Myrtaceæ*, which the hand of man has not planted. We need not go far from the town still to see *Banksias* with their thick coriaceous leaves and singular flower-heads so much like a grenadier's cap, or to come across the much more singular grass trees, with their charred

trunks, grass-like leaves, and tall rod-like scapes of flowers. We can still revel amongst leafless *Acacias*, and *Metrosideros*, strange forms of *Proteaceæ*, and Australian *Bignoniæ*; visit forests where the trees shed their bark instead of their leaves, and all the leaves are turned edgewise; or cast our eyes over large tracts of country still wearing the same evergreen, or rather brownish-green, mantle which it wore when Captain Cook and his naturalists first set foot on the shores of Port Jackson, then the unknown haunt of a few lawless savages, now the capital of Australia and the seat of the Governor-General. Unger, in his 'New Holland in Europe,' has shown us that at one period of the earth's history there flourished in Europe a vegetation very similar to that still beheld in Australia; but that the whole of it has been swept away, to make room for other vegetable forms, leaving no trace behind except what is recorded in the great stone-book of nature. Viewed in this light, the vegetation of New Holland is highly instructive. It is a faithful picture of what the aspect of the flora of our planet must have been ages ago; and on paying a visit to Australia, we are as it were transporting ourselves back to antehistorical periods. The effect which such an inspection produces on one's mind is very singular. It kindles within feelings of curiosity, but no sympathy. We delight in bright green foliage, sweet-smelling flowers, and fruits with some kind of taste in them. But we have here none of all that. The leaves are of a dull green colour, the flowers have no smell, and the fruits, without any exception, are tasteless and insipid. Not a single edible plant has the whole of Australia added to our tables, and Europeans who should have to rely upon what Australian vegetation can supply for their food, would have to share the melancholy fate of Burko and Wills when they tried to eke out their existence by eating the wretched Nardoo seeds of the Australian swamps. [B. 8.]

#### FOREST ON GUAHAN, ONE OF THE MARIANNE ISLANDS.

(Plate VI., p. 368.)

[REFERENCE.—a. *Ficus* with suspended roots; b. *Cycas circinalis*; c. *Cordia*; d. *Cycas circinalis*, old and branched; e. *Cerbera Odollam*; f. *Gigantea Ficus*; g. Slender leaved *Pandanus*.]

As far as the Mariannes are represented by Guahan, the most extensive and southernmost of these islands, they are at once distinguished from the more northern Caroline group by their dry climate, which imparts to the whole country the look of a steppe. The month of March, in which our illustration was taken, is evidently the

dry season; everywhere is aridity, very few trees with fresh foliage are seen in the forest, and perhaps the third part of all is quite leafless. The sea-shores are either kept supplied with moisture by rivulets from the interior, and then overgrown with *Bruguiera* and other Mangroves; or they are sandy, and in that case distinguished by two forms very characteristic of this island—*Cycas circinalis*, very common hereabouts, and a shrubby pyramidal *Casuarina*, which is again met with in the upper steppes of the interior. Banks of coral surround the shores on all sides, making this larger island, as the high Carolines, appear like mountains risen in the centre of extensive coral plains. The plain, shown in our illustration, though destitute of springs, is nevertheless covered with fine tall trees, and although thorny underwood abounds, is on the whole tolerably easy to penetrate. True, there are occasionally considerable thickets of luxuriant *Cycas*, as shown in the centre of our illustration, a few old trees of considerable height forming an agreeable contrast with this rather chaotic group of saplings. Amongst them are a few branching apparently very old specimens, as seen on the left of our plate. The forest trees include one distinguished by its slender growth and thick foliage (the leaves resembling those of the ash), which vernacularly is termed 'Pal-pal,' and esteemed on account of its extremely hard wood. The same remark applies to another tree of similar aspect, the leaves of which are, however, more like those of the myrtle, whilst the bark is pale yellow. A screw-pine, *Pandanus*, though isolated, is rather common. It does not seem to differ essentially from *Pandanus odoratissimus*, and is conspicuous by its slender undulated branches, and long narrow leaves, of which there are comparatively few in each crown. Several species of *Cordia* exhibit their gigantic growth, and are in the dry season but sparingly clad with leaves; here and there their stem is surrounded by a network of creepers. But the most striking of all the trees is a huge species of Fig, the representative of the banyan in this place. It differs evidently in every respect from that of Ualan, the height of which it nowhere seems to attain. Its comparatively tall stem has the appearance of a gigantic bundle of sticks, the component parts of which must be considered as being curiously twisted around each other, and grown together into a compact mass. On the upper end of this rather conical bundle spreads out like an umbrella a crown formed of fantastically twisted branches, which has numerous fine leaves of a dark rather greyish-green. The tree seen on the right-hand side of the foreground is a smaller species of fig, the aerial roots of which have quite the look of creepers. Elegant ferns cover its branches. There is also a species of *Cerbera*, frequently met in the Caroline, Marianne, and Bonine Islands; it resembles in growth and in its leaves the *Terminalia Catappa*, but its principal branches are more rectangular. [B. &amp.]

## CORAL REEF IN THE CAROLINES.

(Plate VII, p. 1157.)

[REFERENCE.—a. *Myrtaceae* tree; b. *Scaevola*; c. *Tournefortia*; d. *Coccoloba*; e. *Artocarpus incisa*; f. *Tournefortia*; g. *Pandanus odoratissimus*.]

Imagine a chain of comparatively long narrow sandbanks, hardly elevated above the level of the ocean, having a general horseshoe-like outline, and sheltered against the waves by a coral reef surrounding the whole. Everywhere within the latter the water is shallow; the bottom, consisting of coral sand, is evidently rising and gradually becoming dry land, so that the open narrow channels crossing the long ridge of land and dividing it into several islands, will in time disappear. The present view represents one of these channels. Standing at the extremity of one island, we look across upon the other. On the right we have an expanded view of the reef, distant about 200 paces, and behind it the surf of the ocean; on the left we behold the basin of unequal depth, surrounded by the horseshoe-like chain, where the prospect is closed by a few islets of this seafaring chain. Such coral islands, but recently risen above the sea-level, exhibit no trace of that vegetation which establishes itself on the older ones. The first green appearing on the hitherto naked sand invariably consists of shrubby *Scaevolas* with small white flowers, which afterwards form also the principal brushwood of the shores, and a specimen of which is represented in the centre of the foreground. The rich juicy foliage of this plant may be well suited to the formation of vegetable mould, in which afterwards a more diversified vegetation finds a home. Next follows a *Tournefortia*, common in all the islands of these seas, which assumes more the look of a small tree, and has a less bushy habit; the silvery grey colour of its leaves forms a strong contrast with the fresh light green of the *Scaevola*. A young specimen of this exclusively littoral plant is seen on the right-hand side of the foreground, and an older one in the distance. Close by will be noticed the delicate foliage of another probably myrtaceous shrub peculiar to the outskirts of these forests; an old fully grown specimen of it is seen in the foreground to the left. In the outskirts of the forest at a distance are found, besides the exclusively littoral plants, other half-shrubby trees. Two specimens of *Pandanus odoratissimus*, so common in all these islands, will easily be recognised by their peculiar habit. Their trunks exhibit numerous crowns. On the right-hand side of the smaller specimen to the left are seen, besides the low *Scaevola* and the just-mentioned *Myrtacea*, a species of *Hibiscus*, with cordate leaves and dark carmine-coloured flowers, which either occurs as a shrub or small tree; and above it a *Calophyllum*, which in other places becomes a stately forest tree, and has a dark green

foliage. Immediately behind it rises an isolated cocoa palm, and more to the right a young specimen of *Barringtonia speciosa*, one of the most beautiful trees of this region, but which grows less freely in these coral islands. Groups of cocoa-nut palms, which suffer little underwood to spring up, show themselves here, and through these may be seen the other end of the forest, a proof of the limited extent of such an island as this. In its centre, where the accumulation of vegetable mould has been going on the longest, stately forest trees have already found a home, among them a large *Eugenia* with lanceolate leaves, and fruits about the size of a large plum of a pale green colour tinged with red, and several bread-fruit trees (*Artocarpus incisa*) of considerable height. [B. S.]

#### VEGETATION OF TENERIFFE, WITH SUCCULENT EUPHORBIAS.

(Plate VIII., p. 476.)

Our illustration introduces us to a wild rocky glen, a barranco, on the east coast of Teneriffe, Canary Islands, where succulent cactus-like *Euphorbias* (*E. canariensis* and *pascuaria*), arborescent *Compositæ* and *Rubiaceæ* are the leading plants. The vegetation has a glaucous look. The *Euphorbia canariensis*, with its straight stiff branches, all springing from the root, is generally seen on the top of rocks and the very edges of precipices, imparting a peculiar feature to the landscape, and contrasting strangely with the tree-like *Kleinia neriifolia* with its long naked branches crowded at the top with tufts of leaves, or *Plocama pendula*, almost resembling a weeping willow, and seen in close proximity to a *Kleinia* in the lowermost right-hand corner of our illustration. *Pyrethrum crithmifolium*, *Conyza sericea*, and *Periploca laevigata*, are three plants also found in this spot. The whole may be taken as a fair illustration of the aspect of the vegetation of the coast region of the Canary Islands, where herbage is so scanty as to afford pasturage to only a few flocks of goats. [B. S.]

#### VEGETATION OF JAVA—TREE-FERNS IN THE FOREGROUND, A FOREST OF AMENTACEÆ IN THE DISTANCE.

(Plate IX., p. 494.)

The traveller in Java, after emerging from the coast region and ascending to the height of 4,000 to 6,000 feet, experiences so

great a change in everything surrounding him, that he can hardly believe himself to be in the same island. Instead of the sultry heat and clammy atmosphere, he now inhales a pure cool air which exercises a delightful reaction upon his spirits. Mountain streams of delicious coolness are met with at every step, and a bright verdure is spread over hill and dale. Our illustration introduces us to a view in the mountains of Java, where a large waterfall dashing over the edge of high perpendicular rocks, looking like a stream of silver from a distance, diffuses an unusual amount of moisture, and favours a great luxuriance of vegetation. Ferns, especially tree-ferns, those palm-like plants, unrivalled in their grace and beauty by any other members of the vegetable kingdom, are here plentiful, and attain often forty to seventy feet in height, their fronds measuring several yards in length. The background of this view is filled by a variety of amentaceous trees, chiefly species of evergreen oaks and *Castanopsis*, growing gregariously together as do their congeners in more temperate climates. [B. S.]

#### SWAMPY FOREST, WITH BANYAN TREES, IN THE ISLAND OF ULAN.

(Plate X., p. 1133.)

[REFERENCE.—a. Spiny Cyperaceous plant; b. *Ficus*, with root-covered trunk; c. Epiphytal *Freycinetia*; d. *Barringtonia acutangula*, young plants; e. *Cordia*; f. *Thamnopteris Nidus*, nestling on a fig stem.]

A description of forest peculiar to the tropics. The adjacent ground, just above high-water mark, becomes inundated by the high tide forcing back the water discharged by rivers and rivulets. A soil thus periodically submerged is never quite dry, and only becomes somewhat firm by the gigantic roots of the trees occupying it. In Ulan, these swampy forests have a twofold character. Where the underwood consists of the *Hibiscus tiliaceus*, they are almost impenetrable; where this is wanting, there is, under the huge bower formed by the crown of large trees, a wider prospect. The underwood is composed of numerous small trees, the crowns of which have not been able to attain the height of the larger trees, and have therefore remained undeveloped. The greater number of them belong to *Barringtonia acutangula*, the fine drooping flower-bunches of which are often seen on the ground. The stems are covered with epiphytal ferns: amongst them *Thamnopteris Nidus*, which imparts a striking character to the landscape. No less ornamental are the isolated *Freycinetias*, which in Ulan mostly grow epiphytically, and are shown quite in the foreground of the picture. The principal features of the plate are gigantic Fig-trees, such as are

often met with in these forests. Those here represented may be assumed as having established, above the heads of other trees, a connection with each other by means of their branches, as is common in this kind of plant throughout India, where entire forests are formed, the stems of which are connected. These latter are the far-famed banyan-trees, regarded in some places as sacred. Among the wonderful phenomena of the vegetable kingdom, as displayed in the tropics, they occupy the foremost place. The most striking peculiarity of these trees is their aerial roots, which, springing from the bark, grow downwards, often from a considerable height, but as soon as they touch the ground they enter it and form a new stem. They also have, in a prominent degree, a tendency to grow together as soon as their different parts come in contact with each other, by which is caused that extremely fantastic shape generally observed in these trees. The present species differs from other kinds of banyan, not only in its astonishing height (our illustration shows only the lower parts of the stems), but especially by its drooping aerial roots. These roots, appearing in bundles of tender, originally disconnected fibres, gradually grow together, and, after reaching the ground, increase in thickness. The new stem thus formed soon loses, more or less, all traces of its original formation. The height of the whole is so considerable that the crowns reach above that of other trees, and here and there form as it were a forest above a forest. The spectator, standing below, soon loses sight of the upper parts of the tree, and only notices accidentally the connection existing amongst trees which at first view would seem to be perfectly unconnected. It has been found impracticable to show in our plate the foliage of this tree; of the crown little was visible, and the leaves are small and of roundish shape. All the young saplings growing about here are those of the *Barringtonia acutangula*, which in these woods assumes an epiphytal character.

[B. S.]

#### VEGETATION OF THE CANARY ISLANDS—VIEW IN THE CALDERA.

(Plate XI, p. 69.)

[REFERENCE.—a. *Pistacia atlantica*; b. *Juniperus Cedrus*; c. *Phanix dactylifera*; d. *Laurus indica*; e. *Pinus canariensis*.]

The Canary Islands are covered with a vegetation singularly characteristic of their geographical position. It is neither strictly tropical, nor typical of the temperate zone, but rather a blending of the forms most peculiar to either. A singular instance of this is presented to us in Webb's view of the Caldera. Surrounded by steep

perpendicular walls of rock 4,000 feet high, that glen enjoys, like a garden conservatory, a temperature always uniform, allowing plants from all heights to flourish in company with each other—the Canarian cedar (*Juniperus Cedrus*) from the most elevated mountain ridge, and *Kleinia neriifolia* from the hot coast region. Here may still be witnessed the strange phenomenon of date-palms and pine-trees growing in the same spot harmoniously together. Leopold von Buch doubted the existence of this vegetative harmony, which had been mentioned by Viera, one of the earliest writers on the Canaries. But the fact is now placed beyond doubt by the united testimony of Berthelot, Webb, and Bolle. But the hand of man, even in this mysterious, almost inaccessible workshop of Nature, the way to which leads through so many dangers along yawning precipices, has not spared the 'Fawns of the wilderness' banished hither. It has allowed the fire to accomplish what the axe was not able to do. In September 1852, says Bolle, there stood only, on one inaccessible rock near the Barranco del Almendrero Amargo, surrounded by pine-trees, one solitary wild palm. Heine's conception of the longing of the two trees, so beautifully expressed in one of his elegies, had here found its realisation.

[B. S.]

#### VEGETATION OF THE CINCHONA FORESTS OF PERU, WITH PALMS AND TREE-FERNS.

(Plate XII, p. 284.)

The valley of San Juan del Oro represented in the accompanying engraving, is a continuation of the ravine of Sandia, the Peruvian province of Carabaya. In this province great spurs run out from the main chain of the Cordillera, and gradually subside into the vast plains, covered with virgin forest and traversed by navigable rivers, which extend to the Atlantic. These spurs form beautiful valleys, such as that of San Juan del Oro, which was once famous for its gold washings. Here torrents and cascades pour down on every side into the river flowing through the valley, and the mountain-sides are clothed with the richest subtropical vegetation. Here may be seen gigantic buttressed trees, festooned with creepers and fringed with graceful ferns and orchids; here are tall tree-ferns, bright-flowering melastomaceous shrubs, and numerous species of palms. Among them are the tall chortá, with its hard serviceable wood; the slender beautiful chiralla (*Euterpe*); the towering muruna (*Trattacea*), with its roots shooting out from eight feet above the ground; and an *Astrocaryum* with thorny leaves, and a lofty stem thickly set with alternate rings of spines. But the

prevailing vegetation of this valley, which is about 5,000 feet above the sea, consists of plants of the cinchonaceous order, with their graceful foliage and panicles of fragrant flowers. Among them are several species of the *Cinchona* which yields the inestimable bark of commerce. It was in these lovely Caravayan valleys that Mr. Clements Markham made a collection of cinchona plants for introduction into India, while he caused other collections of plants and seeds to be made in Northern Peru and Ecuador. Thus the cultivation of those precious quinine-yielding trees, which were until lately only met with growing wild in such valleys as that of San Juan del Oro, is now successfully established in our great Indian possessions. The cascarilleros or bark collectors are represented in the plate as engaged in packing the bark, previous to its being forwarded to the nearest depôt, on the backs of Indians. [B. S.]

#### VEGETATION OF JAVA.

(Plate XIII., p. 840)

[REFERENCE.—a. *Pandanus latifolius*; b. *Eriodendron indicum*.]

Perhaps one of the most singular genera of plants of the eastern hemisphere is that of the Screw-pines (*Pandanus*), so called from their long narrow sword-shaped leaves being arranged around the stem like the windings of a screw, and their fruits having the outward appearance of pine cones. In many instances their stem is branched and tree-like, and in several of our plates specimens of this mode of growth may be seen; but in some instances the stem is simple, and on the left-hand side of our present illustration will be noticed one of the finest and most robust species inhabiting the island of Java, the *Pandanus latifolius*. It grows here in company with feathery palms and the *Eriodendron indicum*; the latter easily recognised by its strictly horizontal branches, arranged in distinct whorls at certain intervals around the stem, and imparting to it the look of a coniferous tree. There are very few plants in the lower coast region of the tropics that have a similar habit. We can only recall *Terminalia Catappa*, and some *Myristicas*. [B. S.]

#### MOUNTAIN VEGETATION OF JAVA.

(Plate XIV., p. 864.)

[REFERENCE.—a. *Rafflesia Rochussenii*; b. *Vanilla*; c. *Freycinetia*; d. *Selliguea*.]

Few spots on the globe support a more luxuriant and diversified vegetation than the island of Java. It is literally teeming

with botanical treasures. Ferns and orchids, palms and oaks, bananas and nutmegs, vines and convolvuli, and an endless host of other plants of which not even the name has penetrated beyond the circle of scientific botanists, cover its surface. In the illustration before us, the artist has contrived to introduce us to a genus of plants which bears the most gigantic of flowers, the famous *Rafflesia*. Nature has equally divided her gifts by according to the New World the plant with the largest leaves (*Victoria regia*), to the Old World that with the largest flowers (*Rafflesia Arnoldii*); and it is not a little singular that both these plants, notwithstanding their prominence, have only been discovered in recent times. *Rafflesia Arnoldii* has flowers often three feet across, but, alas! it has no leaves. The gigantic flowers are seated on the stems of vines, different kinds of *Vitis* (*Cissus*), from which they draw their nourishment parasitically. The species figured in our illustration is *Rafflesia Rochussenii*, not quite so large as the first-mentioned species, surrounded by creeping *Vanillas*, *Freycinetias*, ferns, and other mountain plants. A Dutch gardener, M. Teysmann, was the first who, by carefully observing the way in which *Rafflesias* grow, succeeded in cultivating and flowering them in the Botanic Garden at Buitenzorg in Java, and there is reason to hope that at no distant day we may grow in our hot-houses the largest-flowered plant of the eastern, as we do the largest-leaved plant of the western hemisphere. [B. S.]

#### VEGETATION OF NEW HOLLAND—AN ACACIA 'SCRUB.'

(Plate XV., p. 5.)

Among those plants which by beauty and elegance attract our attention, the *Acacias* occupy a prominent place. Few genera are richer in singular forms, or possess a greater number of truly ornamental species. Their graceful branches, airy foliage, and numerous often fragrant blossoms, have made them favourites with all those who are sensible to the charms of the vegetable kingdom. Especially the *Acacias* called *Phyllodineæ*, are, by their habit, their curiously shaped and highly developed leaf-stalks, the absence of true leaves in old plants, and their diversified tints, even if destitute of flowers, objects of particular interest; and although the species with pinnated leaves do not rank so high in this respect, they are nevertheless not destitute of grace or beauty. The genus *Acacia*, though now considerably reduced, contains upwards of 500 species, a great number of which are peculiar to New Holland and the adjacent islands. Indeed, the *Phyllodineæ* are almost exclusively Australian, only one species, *Acacia Koa*,

being found north of the Equator in the Hawaiian or Sandwich Islands. The acacias are social plants; woods are often entirely formed of them, a fact which increases the commercial importance of several species. Our illustration introduces us to a grove of *Acacias* in Eastern Australia, the burying-ground of Milmeridien. 'On reaching the spot,' says Mitchell, in his *Three Expeditions into Eastern Australia*, 'the natives became silent and held down their heads. Nor did their curiosity restrain them from passing on, although I unfolded my sketch-book, which they had not seen before, and remained there half an hour for a purpose of which they could have no idea. The burying-ground was a fairy-like spot, in the midst of a "scrub" of drooping *Acacias*. It was extensive, and laid out in walks, which were narrow and smooth, as if intended only for "sprites," and they meandered in gracefully curved lines among the heaps of reddish earth which contrasted finely with the *Acacias* and dark *Casuarinas* around. Others girt with moss shot far into the recesses of the bush, where slight traces of still more ancient graves proved the antiquity of these simple but touching records of humanity. With all our art, we could do no more for the dead than these poor savages had done.' [B.S.]

#### VEGETATION OF KAMTSCHATKA, WITH TALL UMBELLIFERS—A BIRCH FOREST IN THE DISTANCE.

(Plate XVI., p. 1189.)

[REFERENCE.—a. b. Tall species of Nettle; a. *Ang. 404.*]

Gigantic umbelliferous plants are more characteristic of the grassy plains of Kamtschatka than of any other part of the Bolschaja Reka district. The tallest among them are the *Heracleum dulce* (?), and a species of *Angelica* of surprising dimensions: it abounds in a few level valleys of the western slopes, principally in the district traversed by the Baunaja Reka, a tributary of the Bolschaja Reka, but is not met with again even in the neighbourhood of its real home. This stately herb is known throughout the country by the Russian name of 'Medweshie Koren' (Bear's root); its hollow stems are dark reddish in the autumn. Another plant is a tall, always gregariously growing nettle (*Urtica dioica*), which contributes an essentially characteristic feature to the country, but which does not occur anywhere in such masses as in these western districts. It is generally ten feet high. Its long stems yield a superior fibre for nettle yarn, which in former times was the only material the Kamtschatkans had for fishing-nets; lately it has in some

measure been displaced, on the Kamtschatka river, by plantations of hemp, which also attains an astonishing height. In the western plains, however, it abounds in such quantities as to have preserved its place in the domestic economy of the inhabitants. The forest at the background consists of *Betula Ermanni*, edged by low willows. [B.S.]

#### CACTUS VEGETATION ON THE BANKS OF THE GILA, NEW MEXICO.

(Plate XVII., p. 256.)

[REFERENCE.—a. *Cereus giganteus*.]

The *Cactaceae* or family of Cactuses furnish perhaps the most singular plants of the present creation. Though a few species are found in the Old World, the bulk of this natural order is confined to the New; and in no part of America do we encounter a greater number both of species and individuals than in Mexico, California, and those countries until recently part and parcel of Mexican territory. In that region, but seldom visited by refreshing showers of rain, the Cactus is the leading plant, imparting a peculiar character to the landscape. The greater number of Cactuses are without leaves, and they generally present fleshy, globular, oblong compressed, or cylindrical stems, densely covered with bundles of spines. An estimate may be formed of the number of these spines, by stating that a single specimen of an *Echinocactus Virens*, the Toothpick Cactus, was found to have 51,000, and a *Pilocereus sentile*, the Old Man Cactus, 71,000. Yet the specimens on which they were counted were only such as had been brought over to England. The giants met with in Mexico and surrounding regions have hundreds of thousands of spines. The favourite haunts of Cacti are the mountain ridges which intersect or border the Mexican tableland, 5,000 to 7,000 feet above the sea. The view chosen as an illustration of this singular vegetation is a landscape on the banks of the river Gila, in the Colorado region of New Mexico, representing the largest form of all known *Cactaceae*, the *Cereus giganteus*, which rises like a huge candelabrum amongst the rocks and ravines of that barren wilderness. In front is a specimen which, though already nearly sixty feet high, is still in vigorous health, and sending forth young side branches. On the right, a little towards the background, is a specimen in a decaying state, showing the form of a woody skeleton; and around them at short distances may be seen younger plants in various stages of development. A few *Opuntias* (Cactuses with compressed articulated stems), feathery *Mimosaes*, the usual companions of

## Illustrations of Phytogeography.

Cactus vegetation, affording shelter against the sun to the young plants, a couple of *Agaves* also typical of Mexico, and some herbs, are distributed over the soil, as yet the roving-ground of the wild Indian. Young plants of *Cereus giganteus* retain a globular shape for several years; and they begin to flower when about ten to twelve feet high. We have actual measurement of stems 46 feet high, so that there is nothing improbable in Colonel Emory's disputed statement that the *Cereus* attains 50 to 60 feet in height. The stem is thickest at or a little above the middle, and tapers upwards and downwards. It is mostly simple, but the older ones have often a few erect branches. Both stem and branches are ribbed, almost fluted like columns, and covered with bundles of spines. The flowers are produced in abundance near the summit, and the fruit has a crimson-coloured, sweet, but rather insipid pulp. [B.S.]

### HYPHÆNE OR DOUM PALM-TREES IN UPPER EGYPT.

(Plate XVIII., p. 612.)

As the traveller is leaving the lower and gradually ascending into the upper portion of Egypt, he meets with the most characteristic of African trees, in the shape of branched Palms, the famous *Hyphæne thebaïca*. They are seen in their full beauty about the cataracts of the Nile, as represented in our plate. The contrast between these trees and the rest of the palm tribe is very great. Whilst most of the palms have a straight pole to which at the upper extremity a number of feathery leaves are attached, we have here a regularly branched tree, somewhat like a screw-pine or *Pandanus*, and large fan-shaped leaves, between which grow large bunches of light yellow fruits with a thick mealy rind, so much resembling in look and taste real gingerbread as to have conferred upon the palm the name of Gingerbread tree. In Cairo and other towns of Egypt these bunches are exposed for sale in the market-places, together with dates, figs, oranges, and other produce of the country. The wood of the tree is used for various domestic purposes; the seed of the fruit is eaten; and the kernels turned into beads for rosaries, and at Kano into toys. From the hieroglyphics we know that it was cultivated more than 4,000 years ago in and about Thebes; but though always a leading tree and a most striking object of the Egyptian landscape of the Upper Nile, the *Hyphæne* does not seem to have exercised, as far as we know, any decisive influence upon ancient Egyptian architecture, like the date palm (*Phoenix dactylifera*) and the Deleb palm (*Borassus? æthiopicum*), for instance, have done. The peculiar swelling

of ancient columns is evidently copied from the trunk of the Deleb palm, of which a singular bulging out is one of the most striking characteristics; whilst the capitals of the column are, in many instances, slavish copies of the crowns of the date-palm, as may be seen in the ancient temple at Edfoo. The exact geographical range of *Hyphæne thebaïca* has as yet to be ascertained. We know it extends considerably into Central Africa, but do not know exactly where it leaves off, as we have no botanical specimens to decide the question, and have to depend upon the information of travellers not able to discriminate between this species and those allied to it. It is certain, however, that there are more than one species of *Hyphæne*, and that some of them at least have a straight cylindrical and unbranched trunk, like that of the generality of palms. [B.S.]

### VEGETATION ON THE ICE-CLIFFS IN KOTZEBUE SOUND, ARCTIC AMERICA.

(Plate XIX., p. 1028.)

The soil of the Arctic region is always frozen, and merely thaws during the summer months a few feet below the surface. But the thawing is by no means uniform. In peat it extends not deeper than two feet, while in other formations, especially in sand or gravel, the ground is free from frost to the depth of nearly a fathom. The roots of the plants, even those of shrubs and trees, do not penetrate into the frozen subsoil. On reaching it they recoil as if they touched upon a rock through which no passage could be forced. It may be surprising to behold a vegetation flourishing under such circumstances, existing independent as it were of terrestrial heat. But surprise is changed into amazement on visiting Kotzebue Sound, where, on the top of icebergs, herbs and shrubs are thriving with a luxuriance only equalled in more favoured climes. There, from Elephant to Eckscholtz Point, is a series of cliffs from 70 to 90 feet high, which present some striking illustrations of the manner in which Arctic plants grow. As may be seen in our plate, three distinct layers compose these cliffs. The lower, as far as it can be seen above the ground, is ice, pure ice, and from 30 to 50 feet high. The central is clay, varying in thickness from 2 to 20 feet, and being intermingled with remains of fossil elephants, horses, deer, and musk oxen. The clay is covered with peat, the third layer, bearing the vegetation to which it owes its existence. Every year, during July, August, and September, masses of the ice melt, by which the uppermost layers are deprived of support and tumble down. A complete chaos is thus created; ice, plants, bones, peat, clay, are mixed in the most disorderly manner. It

is hardly possible to imagine a more grotesque aspect. Here are seen pieces of peat still covered with lichens, mosses, and saxifrages; there a shoal of earth with *Salix* of willow; at one place a lump of clay with *Senecio* and *Polygonum*; at another the remnants of the mammoth, tufts of its hair, and some brown dust which emits the smell peculiar to burial-places, and is evidently decomposed animal matter. The foot frequently stumbles over enormous osteological remains—some elephant's tusks measuring as much as 12 feet in length, and weighing more than 240 pounds. Nor is this formation confined to Eschscholtz Bay. It is observed in various parts of Kotzebue Sound, on the river Buckland, and in other localities, making it probable that a great portion of extreme North-Western America is, underneath, a solid mass of ice. With such facts before us, we must acknowledge that terrestrial heat exercises but a limited and indirect influence upon vegetable life, and that to the solar rays we are mainly indebted for the existence of those forms which clothe with verdure and gay flowers the surface of our planet.

[B.S.]

#### HOLY CROSS ABBEY, COVERED WITH IVY.

(Plate XX, p. 572.)

It is now, thanks to the indefatigable labours of Mr. H. C. Watson, an easy task to give a scientific man a clear idea of the nature and extent of the flora of our British Islands, by explaining to him that the whole territory is divisible into six zones of altitude, the super-arctic, the mid-arctic, the infer-arctic, the super-agrarian, the mid-agrarian, and the infer-agrarian, and into botanical provinces, the boundaries of which are founded upon physical and not upon political differences; and that the vegetation comprised in these divisions is composed of so-called Germanic, Scandinavian, Iberian, Boreal, and North-American types. This explana-

tion, however, would convey but a vague notion of what the vegetation of the British Islands really looked like to one who had not had an opportunity of familiarising himself with the nature of the different zones, or the character of the types. To conjure up any idea of what the British flora really appears like, we should have to speak of waving corn fields, smiling meadows, shady lanes, mossy tombstones, yew-girt churches, gloomy pine woods, purple heather, and golden furze—objects which at once recall scenes and aspects of nature familiarised by the pen of the poet and the brush of the painter. For that reason we have chosen as one of the most characteristic features of the vegetation of the British Islands, Holy Cross Abbey covered with Ivy. This Ivy, it is true, is not peculiarly British, but diffused over the whole of Europe in several distinct varieties, some of which have white, some yellow, and some black berries. The yellow-berried Ivy is confined to the south of Europe, and is the plant with which in times gone by poets were crowned, and which played so prominent a part in the festivals held in honour of Bacchus. The black-fruited variety is much more common, and the one indigenous to our islands. Though it cannot claim the distinction of having encircled the heads of poets, it has furnished the theme of many a poet's song, and in no part of Europe does it thrive with such luxuriance as in the British Islands, especially in Ireland, where, favoured by a humid and mild climate, it ascends the tops of the highest trees, covers with its thick evergreen foliage rocks and walls, and gives a picturesqueness to many an old ruined castle or Gothic abbey. It has been mentioned that in remote times our European Ivy, *Hedera Helix*—at least the yellow-berried variety—was brought from the highlands of Asia; but the Ivy which flourishes in Nepal and throughout the Himalayas with such luxuriance is a species quite distinct, being covered with minute yellow scales instead of white stellate hairs, as our Ivy is. Our *Hedera Helix* is a strictly European plant, which may be said to attain in Britain its highest development, imparting to some of its landscapes a striking and characteristic peculiarity.

[B.S.]

# THE TREASURY OF BOTANY.

**AARON'S BEARD.** *Hypericum calycinum*.

**ABACA.** A name given in the Philippine Islands to *Musa textilis*, which yields Manila hemp.

**ABACOPTERIS.** A name given by Fee to a group of the species of *Nephrodium*, in which the veins of the fronds are united in numerous superposed angles. [T.M.]

**ADATIA.** A small genus of *Lythraceæ*, consisting of Peruvian and Brazilian shrubs with greyish tomentum; opposite, shortly stalked, undivided crenate-serrate leaves, and terminal racemes of rather small, dull purplish, apetalous flowers, with numerous stamens. [J.T.S.]

**ABBREVIATIONS.** Signs to express particular attributes are largely employed by botanists. The following are those most in use:

♂ = male.

♀ = female.

♂ = hermaphrodite, or bisexual.

♂ - ♀ - ♀ = polygamous.

♂ ♀ = dioecious.

♂ - ♀ = monoecious.

♂ - ♀ - ♀ = triecious.

Ⓐ or ○ = annual.

Ⓑ or ♂ = biennial.

℥ = perennial.

℥ = a tree or shrub.

∞ = an indefinite and considerable number of any thing.

! placed after a person's name, indicates that an authentic specimen from that person has been seen.

\* at the end of a citation, denotes that a plant is fully described in the place referred to.

v.v. = seen alive.

v.s. = seen in a dried state.

v.c. = seen cultivated.

v.sp. = seen wild.

" " " When these signs are placed after a number, they express a foot, an inch, or a line respectively; thus,

5' = 5 feet.

5" = 5 inches.

5" = 5 lines.

A very full account of all such signs is given in *Ludley's Introduction to Botany*, ed. 4, li. 384.

**ABELE TREE.** *Populus alba*.

**ABELIA.** A small genus of ornamental shrubs, found in India, China, Japan, and Mexico, and belonging to the natural order *Caprifoliaceæ*. The species are of slender branching habit, bearing opposite leaves and terminal bunches of showy tubular flowers. The genus is distinguished by having an oblong calyx-tube, which is connate with the ovary, and terminated by a five-parted limb of foliaceous segments; a tubular funnel-shaped corolla, with a five-lobed spreading limb; four subdidynamous or nearly equal scarcely exerted stamens; a capitate stigma; and a three-celled ovary, of which two of the cells are many-ovuled, but abortive, and the other one-seeded and fertile, becoming a coriaceous berry. *A. floribunda*, which is a native of Mexico, is a very handsome freely-branching shrub, naturally rather straggling in habit, producing opposite, blunt, ovate, crenate leaves, which are smooth on the surface; it produces large showy blossoms, which come from the axils of the leaves, at the ends of branches, so as to form a pendent leafy panicle. These flowers are a couple of inches in length, rich purple-red, tubular, the tube narrowing at the base and enlarging upwards, and finally spreading out into a limb of five nearly equal rounded lobes. *A. impectans*, a native of China, on the Chamoo hills, has shorter tubular flowers, of a pale rose colour, and forms a lovely dwarf bush, loaded towards autumn with its ornamental blossoms. The few known species are rather objects of ornament than of utility. [T.M.]

**ABELICEA.** A genus of *Ulmaceæ*, containing a single species from Greece and Eastern Asia. It is so nearly related to *Planera* that it would perhaps be better to consider it as a section of that genus, separated from the true *Planera* by its smooth capsule and subsessile leaves. Both have alternate, ovate, crenate-serrate leaves, like the elm. The flowers are hermaphrodite, or polygamous from the non-development of parts. They occur in axillary fasciculate clusters, the inferior flowers of the fascicle being staminal, the superior hermaphrodite or rarely pistilline. There are four or five stamens. The ovoid ovary is one-celled and one-ovuled, and crowned with two spreading styles, which are stigmatose down the inner side. [W.C.]

**ABELMOSCHUS.** The name applied to a genus of plants of the Mallow family

(*Malvaceæ*). The word is derived from the Arabic, signifying musk seed, and was given in allusion to the agreeable odour of the seeds of one species, *A. moschatus*, a native of Bengal. The seeds of this plant were formerly mixed with hair powder, and are still used to perfume pomatum. They possess cordial and stomachic properties and are mixed with coffee by the Arabs. In the West Indies the bruised seeds, steeped in rum, are used both externally and internally as a remedy for snake-bites. *A. eculeatus*, formerly called *Hibiscus* *t.*

ro boiled down in water to form essence of spruce, from which spruce beer is made. *A. balsamea* is the Balm of Gilead Fir, an American tree of much smaller stature than the common spruce fir, with flat leaves, which beneath its cones are erect. It

scope objects.

*A. canadensis*, or the Hemlock Spruce, is a native of North America and Canada, and, from its abundance and eminent beauty, is frequently referred to by the American poets under the name of the hemlock. The bark is much used for tanning purposes.

*A. Picea*, the Silver Fir, is so called from its leaves, which are whitish on their under surface, arranged in two rows, and have their points turned upwards. The cones are erect, of a greenish purple colour, their scales provided with long tapering bracts on their outer surface. The beauty of this tree is such that Virgil has applied to it the epithet *pulcherrima*, 'very beautiful.' It attains a height of 100 feet and upwards, and is a native of Central Europe and Northern Asia. Its timber is not so much prized as that of some other species, but is durable under water, and from its bark exudes a resin which, when purified, is known as Strasburg turpentine.

*A. Larx* is the common Larch fir. Its needle-shaped leaves are at first arranged in tufts, but subsequently become separated one from the other by the lengthening of the branch upon which they grow. They fall off at the approach of winter. The cones are small, erect, somewhat egg-shaped, but blunt-pointed, and the scales have irregular margins: for these reasons the larch is sometimes placed in a distinct genus, and called *Larix europæa*. The wood of the larch is much prized, and very durable; its bark is employed by tanners, and it, as well as the trunk, affords what is known as Venice turpentine, which differs from most other kinds of turpentine in not becoming hard by exposure to the air for a considerable period. A kind of sugary matter exudes from the larch in summer time, and is collected under the name of Manna of Briançon. The larch attains a great size, and forms a most beautiful object on the mountain sides in Switzerland and other Alpine districts of Europe, and is much cultivated in this country for the sake of its timber, while its pyramidal form, pendent branches, light green leaves, and purplish cones render it a very beautiful tree for ornamental purposes. Round some of the meres or lakes in Shropshire the larch is abundantly planted. Its leaves fall into the water, and become felted together into large ball-like masses by the agency of a peculiar species of *Conserva*. These larch balls may be met with of all sizes, from that of a marble to that of a child's head; they lie at the bottom of the lake, and are washed up round its margins.

*A. Cedrus*, or, as it is sometimes called, *Cedrus Libani*, is the well-known Cedar of Lebanon. It is principally distinguished

thickening soups, or rather from mucilage well fits them. The young pods are gathered green and pickled like capers. The plant is cultivated in the south of France for the sake of its pods, which when ripe are of a conical shape, covered with hair, and about an inch in length. All the species of this genus furnish excellent fibre. The genus is botanically characterised by a deciduous ten-leaved involucre; a spathe-like, tubular, conical, five-toothed calyx; spreading petals; one-celled anthers; a style cleft into five divisions at the top; a capsule with five cells and five valves, whose edges are not bent inwards. [M. T. M.]

**ABERRANT.** Something which differs from customary structure. Also a group of plants which stands intermediate, as it were, between two other groups:—e.g. *Fumariaceæ*, which are by some regarded as an aberrant group of *Papaveraceæ*.

**ABIES.** In this genus of the cone-bearing family (*Coniferae*) are included the plants commonly called Firs, in contradistinction to pines (*Pinus*). The firs are for the most part lofty trees, with small, narrow evergreen leaves, placed in two rows along the sides of the branches, or occasionally tufted. The flowers are unisexual; but the male flowers are borne upon the same trees as the female ones, and both kinds are produced in catkins. The mature female inflorescence constitutes the cone, which is usually of a cylindrical form, consisting of a number of woody scales overlapping each other, but not thickened at their points, as in pines. The species of fir are remarkable as timber trees, and for yielding turpentine, &c.

*A. excelsa* is the common or Norway Spruce Fir, which when well grown is a handsome tree, sometimes reaching the height of one hundred to one hundred and fifty feet. The leaves are of a dull green colour, of a four-cornered shape, and sharply pointed; the cones are cylindrical, pendulous, their scales bluish, or slightly waved or toothed. The tree is a native of Norway, Russia, and the mountainous parts of Europe generally, thriving best on a damp soil. Its timber is much used under the name of white deal. From its trunk exudes a resin commonly called frankincense, which, when melted in water and strained, constitutes Burgundy pitch. The young leaf-buds or shoots of this and other species

from the larch by its evergreen leaves, and by its cones, which are from three to five inches in length, oblong, blunt, erect, and composed of numerous densely packed scales of a purplish-brown colour. They are not fully ripened till the third year, and remain on the tree for several years. The tree is a native of the mountains of Lebanon and of Taurus, where its majestic form and huge spreading branches render it a very prominent feature. A recent traveller in Syria, Mr. Urquhart, thus speaks of it. 'The trunk dividing at from ten to twenty feet from the ground, the branches contorted and snake-like, spreading out as from a centre, and giving to the tree the figure of a dome; the leaf-bearing boughs spread horizontally, the leaves or spicula point upwards, growing from the bough like grass from the earth. The leaves are thick and short, about an inch in length. The cones stand up in like manner, and are seen in rows above the straight boughs. The timber is in colour like the red pine.' The wood has been said to be very durable, but there is some reason to think that the wood of a species of *Thuja* has been mistaken for that of the cedar of Lebanon, which is not so indestructible as was once supposed. From the noble appearance that the tree presents, it is frequently met with in parks, &c., the habit or general appearance of the tree, and the arrangement of its branches, differing considerably in different individual trees. Many magnificent trees of this species are to be seen in Blenheim Park, Oxfordshire; but scarcely any two are alike in the disposition of their branches or the colour of the leaves.

*A. Deodara*, or *Cedrus Deodara*, the Deodar or Indian Cedar, differs from the cedar of Lebanon, in having the cones placed on short thick stalks; and the scales of the ripe cone fall off, instead of being persistent, as in the Lebanon cedar, while its leaves are longer and more distinctly three-sided than in that plant; but it is by no means certain that the two plants are really specifically distinct. The individual plants forming the species of this genus differ so remarkably in habit and general appearance one from the other, that great caution is necessary in dogmatizing as to the distinctness of this or that form. The Indian or Deodar cedar is a native of Nepal and of the Himalayas, where it attains a height of from fifty to one hundred feet and upwards. Its timber is of great value from its durability, and it furnishes a turpentine which is much employed as a medicament by the natives in North-Western India. It was introduced into this country in the year 1822, and is now much cultivated as an ornamental tree, from its elegant form, gracefully pendent branches, and the glaucous hue of its foliage.

*A. atlantica*, the Algerian, or Mount Atlas Cedar, called also *Cedrus atlantica*, forms almost the entire vegetation of the upper mountainous regions of certain provinces of Algeria. According to M. Cosson, there is no doubt but that this is a mere variety of the Lebanon cedar, from which it differs

in the length of its leaves. The form and size of the cones are too variable to constitute a point of distinction.

Several other species of this genus are grown in this country as ornamental trees, among which *A. bracteata* and *A. Douglasii*

*Abies Douglasii* (cone).

may be mentioned as particularly interesting species. [M. T. M.]

**ABNORMAL.** Opposed to usual structure. Thus, stamens standing opposite to petals, and nowhere else, as in *Rhinnadea*, are abnormal, it being usual for stamens to be alternate with petals, if equal to them in number. Leaves growing in pairs from the same side of a stem, as in *Atropa Belladonna*, and flower-stalks adherent to the midrib of a bract, as in *Tilia*, are also abnormal.

**ABOLIA radiata** is a curious little Orchid from New Grenada, differing from *Odontoglossum* and *Oncidium* in having a slender delicate caudicle, and solid pollen masses. The flowers are brown, with yellow streaks, and a white lip.

**ABOLBODA.** A genus of *Xyridaceæ*, containing six or seven species of stemless plants, growing in tufts in the marshes of South America. This genus is nearly allied to *Xyris*, but differs from it in having the ovary and capsule always three-celled, while the predominant form in *Xyris* is one-celled, and, when otherwise, but imperfectly three-celled. The ovules also are attached to the central axis, while in *Xyris* they rise from parietal placentae. [W. G.]

**ABORTIVE.** Imperfectly developed; as abortive stamens, which consist of a filament only; abortive petals, which are mere bristles or scales.

**ABRICOT SAUVAGE.** A French name, used in the West Indies for the Mammee apple. Also applied in Cayenne to the fruit of *Couroupita guianensis*.

**ABRODICTYUM.** A name given by Presl to a very elegant species of *Trichomanes*, differing only in the form and arrangement

of the cells of its tissue. *A. Cumingii* is now generally called *T. Smithii*. Van den Bosch has revived the name under the form of *Habrodictyon*. [T. M.]

**ABROMA.** The name given to a genus of the Sterculiaceae family. They are small trees, with hairy lobed leaves, and terminal or axillary clusters of yellow or purple flowers. Their fruits are capsular, five-celled, with five membranous wings, and many seeds in each cell. They are natives of India, Java, and the tropical parts of New Holland. Three species are known: one of them, *A. angusta*, is the Wolnut Camul, or Wullut Camul, of the Bengalese. Its bark abounds with strong white fibres, which afford a good cordage. The plant grows quickly, and may be so managed as to afford three crops of cuttings in the year. The bark is separated from the shoots by maceration in stagnant water. From four to eight days is sufficient to effect this in hot weather, but in the cold season a much longer time is required. The fibre requires no artificial cleaning. Cord made from it, though not to be compared with that of hemp, is strong, and is not liable to be weakened, as many others are, by exposure to wet. [A. A. B.]

**ABRONIA.** A small genus of monocotyledonous plants, belonging to the order *Nyctaginaceae*. In this genus the leading peculiarities of structure are a five-leaved involucre, surrounding a close head of many flowers; a coloured corolla-like salver-shaped perigone, having the tube inflated below, and the deciduous limb five lobed, spreading, with obovate lobes; five hypogynous included stamens, connate at the base, and having oblong anthers; a simple style with a club-shaped stigma; and a one-celled ovary containing one erect ovule. There are but few species known, and these natives of N. W. America. *A. umbellata*, one of the best known, is a handsome dwarf trailing perennial herb, producing opposite stalked, bluntly ovate, rather succulent leaves, and, from their axils, long-stalked, close umbels of pretty primula-like flowers, of a purplish rose colour. These flowers consist of a coloured calyx, the corolla being wanting; and they are very deliciously fragrant, especially towards evening. The other species are of similar character. They are not applied to any use. [T. M.]

**ABRUPT.** Suddenly terminating; as abruptly pinnated, when several pairs of leaflets are formed without any intermediate one at the end.

**ABRUS.** The name of a genus of Leguminous plants, of which five species are enumerated. *A. precatorius*, the best known, was originally a native of India, but is now found in the W. Indies, the Mauritius, and most tropical regions. It is chiefly remarkable for its small nearly globose seeds, which are of a brilliant scarlet colour, with a black scar indicating the place where they were attached to the pods. These seeds are much used for necklaces and other ornamental purposes, and are employed in India as a standard of

weight under the name of Rati. The weight of the famous Koh-i-noor diamond was ascertained in this way. There is a variety with perfectly white seeds. The roots are made use of in the same manner as the roots of the liquorice plant. The *Abus precatorius* is of twining habit, with pinnate leaves, numerous stalked flowers in axillary clusters, a bell-shaped four-lobed calyx, and a pale purple corolla, succeeded by an oblong compressed pod containing four to six seeds. [M. T. M.]

**ARSINTHE.** (Fr.) *Artemisia Abinthum*. — **PETITE.** *Artemisia portica*.

**ABUTILÆA.** An E. Australian plant, not really distinct from *Abutilon*. [A. A. B.]

**ABUTILON.** A genus of *Malvaceae* (Malvaceae family), known by having a cup shaped calyx without an involucre, an ovary of five or more carpels, which are divergent at the apex, and naked within, containing three or more ovules, and inseparably adherent by their inner angles. They are annual or shrubby plants, often very ornamental, inhabiting the W. Indies, Siberia, and even Piedmont. The flowers of one species, *A. esculentum*, are used as a vegetable in Brazil. *A. indicum* and *polyandrum*, Indian shrubs, furnish fibre fit for the manufacture of ropes. Their leaves contain a large quantity of mucilage. [M. T. M.]

*A. striatum*, *venosum*, *insigne*, and some other species, are favourite plants, often seen in our gardens and greenhouses. They have palmately-divided or heart-shaped leaves, and axillary pendulous flowers, the petals of which converge so as to give them a semi-globular bell-shaped outline. They are of considerable size, yellow or white, beautifully veined with red. [T. M.]

**ACACALLIS cynnea.** Under this name Lindley describes a handsome Brazilian Orchid with the habit of a *Huntleya* and large light blue flowers. It is distinguished from that genus by having a long narrow hypochil with a deep sac at its point, surrounded by a five-lobed border. It was found by Spruce, on trees near the Rio Negro.

**ACACIA.** A genus of shrubs or trees belonging to the *Mimosa* tribe of the Leguminous family. Its principal points of distinction are the calyx, which is provided with four or five teeth, the corolla of four or five petals, the numerous stamens, and the pod, which is not divided into joints, and which does not contain a pulp. The great number of the stamens and the nature of the pod particularly distinguish this genus from the allied genus *Mimosa*. The flowers, which are small, are collected in large numbers in globular heads, or in long spikes. The true leaves are twice or thrice pinnated, and the small leaflets, being very numerous, confer a very elegant feathery appearance on the plants, but in many of the species, particularly those found wild in New Holland, the true leaves are seldom or never developed, but, to compensate for their absence, the leaf-stalk, which is usu-

VEGETATION OF NEW HOLLAND AND AN ACACTIA SCRUB  
(After Mitchell)

ally more or less cylindrical, and of small dimensions, becomes flattened out, and assumes a leaf-like appearance; these dilated leaf-stalks, or, as they are technically termed, *phyllodes*, fulfil the functions of the leaves, and are of very varied form in the different species. They are always so placed that their edges look upwards and downwards, so that by this means, as well as by the arrangement

*Acacia argyrophylla* (with phyllodes).

of the veins, they may be distinguished from true leaves, which have their surfaces looking upwards and downwards. It results from the singular position of these organs that the trees possessing them give but little shade, as the light is not intercepted in its passage to so great an extent as it is by the leaves of ordinary trees. This peculiar direction of the leaf is not confined to the acacias, but is also found in other Australian trees: e. g. *Eucalyptus*. At the base of the leaf-stalk of the acacias, where it joins the branch, are two small stipules, which are sometimes represented by spines.

The species of acacia are very numerous, and widely diffused in the warmer regions of the globe. *A. gummiifera* is found in Mogador. *A. Nemu* is abundant in the environs of Nagasaki, Japan. *A. glandulosa* and *A. brachyloba* adorn the banks of the Mississippi. Some of the species are of great importance, as furnishing gum; others contain an abundance of tannin, which renders them useful for tanning purposes, and in medicine as astringent drugs. Gum arabic, or gum acacia, is an exudation from various species of acacia, such as *A. Verck*, *A. arabica*, *A. vera*, *A. Adansoni*, and others, for the most part natives of Arabia, Barbary, and the East Indies. Gum Senegal is a similar product from other species of the genus. Some Australian kinds called Wattle trees furnish gum. The drug known as catechu is prepared from various trees, but especially from *Acacia Catechu*, the wood of which is boiled down, and the de-

coction subsequently evaporated, so as to form an extract much used in medicine as an astringent. The bark of *A. arabica* is used in India for tanning leather, under the name of Babul bark; that of *A. Melanoxylon* is used for the same purposes in Australia. The pods of other species are likewise similarly employed in Egypt and Nubia. Many furnish excellent timber, and the flowers of one species, *A. Farnesiana*, yield a delicious perfume. The pods of *A. concinna* are used in India like those of the soap-nut for washing the head; the leaves also are acid, and used in cookery like those of tamarinds. The pounded seeds of *A. Niopo* are employed by certain of the Indian tribes on the river Amazon as the basis of a snuff, into the composition of which lime and the juice of a species of *Cocculus* also enter; its effects are to produce a kind of intoxication and invigoration of spirits. Many kinds are cultivated in greenhouses in this country, for the beauty of their flowers or for their foliage; some few even, such as *A. Julibrissin* and *A. lophantha*, will succeed out of doors in warm situations. The name *Acacia* is also commonly given to the Locust-tree of North America, a very different plant. See ROBINIA, and MIMOSA. The aspect of an *Acacia* scrub, which is one of the characteristic features of Australian vegetation, is shown in Plate 15.

[M. T. M.]

**ACACIA BLANC.** (Fr.) *Robinia Pseud-Acacia*. — BOULE *Robinia umbra-cultifera*. — DE CONSTANTINOPLE. *Acacia Julibrissin*. — DE SAINTE-HELENE. *Acacia vestita*. — DE SIBERIE. *Caragana frutescens*. — PARASOL. *Robinia umbra-cultifera*.

**ACACIA, BASTARD or FALSE.** *Robinia Pseud-Acacia*, sometimes called the Locust-tree. — ROSE. *Robinia hispida*.

**ACENA.** A genus of the *Sanguisorbaceæ*. They are small herbs, mostly with woody stems. The leaves are unequally pinnate, the flowers small, white or purple, borne on scapes and arranged in terminal balls, or sometimes in spikes. Their calyxes are often beset with slender spines which are furnished at their apex with reflexed bristles. *A. ovina* is a common weed in S. Australia and Tasmania, and is troublesome in grazing districts from the bristles of the fruit getting entangled in the wool of the sheep; it is also a pest to housewives from their adhering to linen exposed to dry on the grass; and, as well as many of the species, a common annoyance to travellers by catching their dress. A decoction of the leaves of *A. Sanguisorba* is used in New Zealand as tea and as a medicine. It is the Piri Piri of the natives. There are upwards of forty species in the genus, chiefly natives of the temperate regions of S. America; commencing in California, they extend through the Andes (where some of them reach the elevation of 15,000 feet) to Cape Horn, and attain their maximum in Chili. [A. A. B.]

**ACALYPHA.** A large genus of Spurge-worts (*Euphorbiaceæ*), comprising upwards

of a hundred species, which are more or less distributed over all tropical and subtropical regions, attaining their maximum, however, in S. America. A goodly number are annual, but the great mass perennial shrubby plants, having much the appearance of nettles, and readily known in the family from their nettle-like leaves and the disposition of their flowers, which, usually of a green or reddish colour, and inconspicuous, are disposed generally in erect or drooping bracted spikes, which arise singly from the axils of the leaves or the end of the shoot, and vary in length from an inch to a foot, the upper portion of the spike bearing sterile, the lower fertile flowers, or the entire spike devoted to the one or the other. The sterile have a calyx of four triangular lobes, enclosing eight to sixteen stamens, whose curious flexuose anther cells are quite distinct from each other, and stand out nearly at right angles to their stalk. The fertile flowers have a calyx of three to five divisions, and a three-branched style, the branches deeply ramifying, crowning a three-lobed ovary, which, when ripe, is a three-celled and three-sided capsule of the size of a small pea. The Stringwood of St. Helena (*A. rubra*) is interesting as being one of a comparatively small number of plants now known to be extinct. It formed a beautiful small tree, and got its name of stringwood from the long spikes of reddish-coloured sterile flowers which hung in great profusion from the twigs. *A. indica*, an annual Indian weed, one to two feet high, with nettle-like leaves, and flower-spikes having toothed leafy bracts, has, according to Nimmo, roots which attract cats quite as much as do those of Valerian. This plant is the Cupament of Rhedeo, who says the root bruised in hot water is cathartic, and a decoction of the leaves laxative.

[A. A. B.]

**ACAMPE.** Under this genus Lindley collects a few Indian and Chinese epiphytal orchids, formerly referred to *Vanda*, from which they differ in having small brittle flowers with a lip adnate to the edges of the column. They are of no interest except to botanists. The handsomest is *Acampe* (formerly *Vanda*) *longifolia*, a fine-looking species with small yellow flowers, occasionally met with in gardens.

**ACANTHACEÆ.** An order of monopetalous exogens, belonging to Lindley's Bignonioid Alliance, and nearly related to Scrophulariads. In tropical regions they are extremely common, constituting a large part of the herbage. Nevertheless the genus *Acanthus* is found in Greece, and one species inhabits the United States. In a majority of cases *Acanthaceæ* are to be recognised by the presence of large leafy bracts, in the axils of which the flowers are partly concealed, and also by their calyx being composed of deeply imbricated sepals forming a broken whorl. But their most exact difference from other orders of the Bignonioid Alliance consists in the singular structure of their placenta, which expands into hard pro-

cesses, which are most commonly hooked. In the form of their embryo they agree with bignoniads. They are of little importance to man. The greater part are mere weeds, but some are plants of great beauty, especially the species of *Justicia*, *Aphelandra*, and *Ruellia*. For the most part they are mucilaginous and slightly bitter; occasionally the bitterness increases, and they become pectoral medicines; some are dyers' plants. The genuine *Acanths*, formerly called *Branc-uraines*, are emollients, as

capit in Archi se uic.

also is *Anisotes trisulcus*, an Egyptian plant. About 1500 species are mentioned in books.

**ACANTHE D'ALLEMAGNE. (Fr.) Heracleum Sphondylium.**

**ACANTHODIUM.** A genus of Acanthaceous plants, distinguished by Deille from the genus *Acanthus* by reason of its two-celled pod, each cell of which contains one compressed seed, the radicle or young root of which is placed near the scar of the seed, or that part where it is attached to the pod, whereas in *Acanthus* the rootlet is placed at a distance from the scar. The only species, *A. spicatum*, is a native of Egypt. It is provided with a very short stem, from which proceed three or four spikes of flowers, each provided with very spiny bracts. [M. T. M.]

**ACANTHOGLOSSUM.** An epiphytal orchid from Java, now merged in *Pholidota*.

**ACANTHOLIMON.** A genus of *Plumbaginaceæ* containing about forty species, most of which are natives of Persia, Asia Minor, and Greece. The technical characters are the union of the five styles at the base, and the capitate stigmas; but they are readily distinguished from their allies by their rigid, sharp-pointed leaves, which resemble those of juniper. The stems are very short, and much branched, so that the plants form dense prickly cushions on the rocks on which they grow; the flower-stalks are simple or forked; the spikelets in

a spike which is generally lax; the calyx white, its limb surrounding the rose-coloured corolla like a frill. *A. glumaceum* is a very pretty garden rock plant. [J. T. S.]

**ACANTHOPHIPPIUM.** A genus of terrestrial Orchids allied to *Bletia*, with large, fleshy tubular flowers, growing almost at the base of the leaves. These flowers are white or pink, and occasionally streaked with a deeper colour. The few species that are known come from the tropical regions of Asia.

**ACANTHUS.** The genus from which the order *Acanthaceae* derives its name. The species are all especially remarkable for the beauty of their foliage. The calyx consists of four unequal pieces, the two side ones being much smaller than the other two; the corolla is also irregular, and has but one lip; the stamens are four in number, one pair longer than the other; the anthers are one-celled, and covered with hairs; the capsule is two-celled, each cell containing two rounded seeds. *A. mollis* and *A. spinosus* both grow in Italy, Spain, and

*Acanthus spinosus.*

south of France, &c. The leaves of the latter plant are supposed to have furnished to Callimachus the model for the decoration of the capital of the columns in the Corinthian style of architecture. Several species are cultivated in this country, but are ill adapted to resist frost. [M. T. M.]

**ACARPHÆA.** A genus of the Composite family (*Compositæ*) containing but one species, *A. artemisiifolia*, a native of California. It is an herb with ragwort-like leaves three to four inches long, glandular above, and hoary beneath; the flower-heads few and stalked, the florets yellow. The name has reference to the absence of the chaffy pappus of *Chamaetis*, and the chaffy receptacle of *Madia*, to both of which it is allied. The name has been by mistake printed *Acicaphæa*, instead of *Acarphæa*, in some books. [A. A. B.]

**ACAULIS.** Having a very short stem:

literally stemless, but a plant without a stem cannot exist, unless it is a mere vesicle.

**ACAULOSIA.** A diseased condition of plants, in which the stem is imperfectly developed or wholly wanting. Its formation may moreover be retarded by the main powers of vegetation being directed to some other quarter, as in turnips to the formation of an enormous root. There may moreover be stemless varieties of some particular species; the primrose representing, for instance, a form of the cowslip in which the axis is reduced to little more than a point. The common hyacinth sometimes flowers imperfectly without any elongation of the stem, a state which arises from injury or decay of the roots; and from similar affections a like condition may be produced by heat. The stem of *Cnicus aculis* is not developed in poor dry pastures, though it occasionally acquires a foot or more in length. The stunted growth of trees also may arise from a like cause, but is more frequently produced by actual injury, intentional or otherwise. [M. J. B.]

**ACCRESCENT.** Growing larger after flowering. The calyx of *Melanorrhæa*, which is small and green when in flower, becomes large and leafy when the fruit is ripe, and is therefore accrescent.

**ACCUMBENT.** Lying against anything; used in opposition to incumbent, or lying upon something; a term employed in describing the embryo of Crucifers.

**ACER.** This name includes the Sycamore and the Maples, Aceraceous trees indigenous to the temperate regions of both the Old and New World. They are mostly of rapid growth, and easily propagated. For these qualities, and for the beauty and variety of their foliage, the species are much planted in England for ornamental purposes, while in America one species has great economic value, being employed in the manufacture of sugar, a substance which is found more or less in the sap of all. The flowers, though they display no striking colours, attract the attention from their number, graceful arrangement, or the multitude of winged insects which, at a season when flowers are scarce, resort to them for food. The leaves are mostly lobed and toothed, in some species very large; and the seed-vessels (called *samara* by botanists), which are winged capsules, each containing a single seed, and united by their bases into pairs, are strongly characteristic of the family.

The common Sycamore, *A. Pseudo-Platanus*, abundant as it is in England, and readily though it propagates itself by seed, is, on good grounds, supposed not to be indigenous, but to have been introduced from the European continent in the fourteenth century. Of a tree so well known it is unnecessary to give any description. Its uses are numerous. The wood is used for various articles of domestic furniture, musical instruments, and toys; as fuel it is

said to be the most valuable of all woods, and it may be converted into excellent charcoal. From the sap collected in early

*Acer Pseudo-Tataricum.*

spring, sugar may be made, but not in remunerating quantities. In Scotland it is popularly known as the Plane. The name kycamore was given to it at an early period, from a supposition that it was the tree mentioned in the New Testament, which, however, as the etymology indicates, is a species of fig (*figum*, a fig, and *morus*, a mulberry-tree, resembling the former in its fruit, and the latter in its leaf), *Ficus Syco-*

The Maple (*A. campestre*) is a low hedge tree most conspicuous for the golden and purple tints of its foliage in autumn. The gnarled stems and knotted roots of this species have long been prized by turners and cabinet-makers for making choice articles of furniture. The wood also makes excellent fuel, and the best of charcoal. But the most important species of this family is the Sugar Maple (*A. saccharinum*), a native of North America. This tree forms extensive forests in Canada, New Brunswick, and Nova Scotia, and yields a saccharine juice in such abundance that maple-sugar is an important article of manufacture. It has been computed that in the northern parts of the two States of New York and Pennsylvania there are ten millions of acres which produce these trees, in the proportion of thirty to an acre. The season for tapping is in February and March, while the cold continues intense and the snow is still on the ground. A tree of ordinary size yields from fifteen to thirty gallons of sap, from which are made from two to four pounds of sugar. The tree is not at all injured by the operation, but continues to flourish after having been annually tapped for forty years without interruption. Greater facilities of intercommunication and the decreased cost of cane-sugar, which is far superior, have tended of late years greatly to check the manufacture of sugar from the maple. Old trees of this species

are liable to a peculiarity of growth which gives to their timber the knotted structure known by the name of bird's-eye maple. The common Maple is the badge of the clan O'plian.

The wood called 'curled maple' is obtained from old distorted trunks of *A. rubrum*, a native of America. There are several remarkably ornamental Maples now in our gardens which have been introduced from Japan; these have small leaves, often deeply lobed, the lobes much dissected, and beautifully variegated with white, pink, or purple: they are chiefly varieties of *A. palmatum* (*p. polymorphum*). For an enumeration of other species, see Lawson's *Arboretum*. See also *Nipundo*. [C.A.J.]

**ACERACEÆ** (*Acer*; *Acerines*; the order of *Maples*). A natural order of trees and shrubs inhabiting Europe, the temperate parts of Asia, the north of India, and North America. The order is unknown in Africa and the southern hemisphere. The most important product is the sweet sap of some species, from which sugar is extracted. It is said, however, that their juices become acrid as the season advances. They yield a light useful timber. The bark of some is astringent, and yields reddish brown and yellow colours. The order only contains three genera, and rather more than fifty species.

**ACERANTHUS.** A genus of *Berberidaceæ* containing a single species from Japan, a slender plant nearly allied to *Epimedium*, but having plain or spurless and not spurred petals. [W.C.]

**ACERAS.** An *Orchis* without a spur, there being no other difference between the two genera, except that *Aceras* has only one pollen gland instead of two. The Man Orchis, *Aceras anthrophophora*, so called because of a fancied resemblance between its lip and the body of a man hung by the head, is common in meadows and grassy slopes all over Europe. It has greenish yellow flowers bordered with red, a pair of oblong knobs or tubercles for its roots, and a heavy rather unpleasant odour. *Aceras hircina*, theizard Orchis, is a much finer and rarer plant with long spikes of dirty rose-coloured flowers, the middle lobe of whose lip has the form of a long, twisted strap; they emit an unpleasant odour like that of a goat. This species is occasionally found in chalky districts all over the temperate regions of Europe. Haller says that the bruised root increases the flow of milk in milk cattle. Other species occur in Asia, reaching as far as Gossain than in the Himalayas; and one (*A. secundiflora*) found in Barbary and Madeira, is occasionally seen living in the gardens of curious collectors.

**ACEROSE.** Needle shaped; as in the leaves of beeches and pine trees.

**ACETABULARIA.** A beautiful genus of calcareous green-spored *Alga*, the species of which resemble little umbrellas or such delicate gill-bearing fungi as *Coprinus pilcatia*. An erect articulated stem bears above a whorl of threads which are united laterally so as to form an umbilicate orbicular disk, from the centre of which arises a bunch of delicate branched threads. The

most remarkable species is not uncommon in the Mediterranean, but none has yet been observed on our own coasts. [M. J. B.]

**ACETABULUM.** The receptacle of certain fungals.

**ACHÆNE** or **ACHENE.** Any small, brittle, seed-like fruit, such as *Linnæus* called a naked seed.

**ACHANIA.** The name given to genus *Malva*.

Mexico, the West Indies, &c. The calyx is double, the outer of many pieces, the inner tubular and five-toothed; there are five petals with appendages at their base; the filaments are united into a spirally twisted tube, bearing the anthers on the summit; and the flowers are succeeded by a five-celled fruit. *A. Malvastrum* is remarkable for the beauty of its scarlet axillary flowers, and its green, heart-shaped, sharply-pointed leaves. [M. T. M.]

**ACHARIA.** A genus of erect, slender, glaucous Cape herbs, belonging to the *Papaveraceæ*. The only species, *A. trugolida*, has alternate deeply trifid leaves, and axillary unisexual flowers, with a three-leaved involucre, and a campanulate trifid calyx. The male flowers have three stamens, alternating with three scales. In the females three scales surround the one-celled stipitate ovary. [W. C.]

**ACHE.** (Fr.) *Apium*. —**DEMONTAGNE.** *Levisticum officinale*. —**DES CHIENS.** *Ethusa Cynapium*.

**ACHE'E.** (Fr.) *Polygonum aviculare*.

**ACHIAI.** An Eastern condiment, formed of the young shoots of *Bambusa arundinaria*.

**ACHILLEA.** A name anciently given to a plant 'wherewith Achilles cured the wounds of his soldiers.' It is now applied to a family of plants belonging to the natural order of Compound flowers. Most of the species have deeply divided woolly leaves, and bear their flower heads, which are white, yellow, or purple, in flat clusters (corymbs) at the extremity of the stem. Two species only are native in Great Britain:—*A. Farnesula*, Sneezewort, an herbaceous plant, a foot high or more, bearing heads rather less in size than a daisy, which have the disk, as well as the ray, white. This is frequent in moist meadows, especially in the hill countries. It derives its name from its alleged property of exciting sneezing when pulverised, a virtue which it probably possesses, though not to an extent beyond that of many other plants undistinguished by special names. *A. Millefolium*, Milfoil or common Yarrow, is an herbaceous perennial, with tough upright stems, more or less woolly deeply-cut jagged leaves, and flat corymbs of flower-heads, containing very few florets, which are either white, pink, or, rarely, deep purple. Its properties are highly astringent, and it was anciently much prized as a vulne-

rary. The older English botanists called it Nose-bleed, 'because the leaves being put into the nose caused it to bleed.' Several foreign species are cultivated as border plants, and are conspicuous either by their flowers or hoary foliage. [C. A. J.]

**ACHIMENES.** An extensive genus of very handsome tropical and sub-tropical herbs, furnished with scaly underground tubers, by which they are perpetuated. They

are to be found in the original kinds, have been obtained in the cultivated state. They belong to the order *Gesneraceæ*, and their most obvious peculiarities consist in a five-parted sub-equal calyx, the tube of which is joined with the ovary at its base; a funnel-shaped corolla, of which the tube is somewhat oblique, and gibbous behind at the base, and the limb spreading five-lobed and nearly equal; four didynamous included stamens inserted on the tube of the corolla, with the rudiment of a fifth; a simple style with a subcapitate obsoletely two-lobed stigma; and an ovary coherent with the base of the calyx, bordered by an annular or ring-formed glandular disk, one-celled, containing many ovules, which are attached to a pair of parietal placentae. They have fleshy erect stems; opposite, serrated, often hairy leaves, and axillary flowers, the pedicels of which are not unfrequently accompanied by little scaly, bulbiform tubers, like those produced at the base of the stem beneath the surface of the ground. The genus has been divided into several by modern botanists, but few of the proposed groups have been generally received. The principal of these new genera, in addition to *Achimenes* itself,—which is made to consist of erect herbs with axillary flowers, having a membranaceous entire glandular ring, and a two-cleft stigma,—are the following:

*Kolkieria*: dwarf herbs with a terminal racemose inflorescence, a membranaceous nearly entire glandular ring, and a stomatomorphous stigma.

*Locheria*: erect herbs, with axillary or sub-panicled flowers, a thickened fleshy nearly entire five-angled glandular ring, and a two-cleft stigma.

*Guthnickia*: erect herbs, with axillary flowers, a thickened fleshy nearly entire five-angled glandular ring, and a stomatomorphous stigma.

*Scheeria*: erect herbs, with large axillary flowers, a thick fleshy subentire glandular ring, and stomatomorphous stigma.

*Mandrola*: erect herbs, with axillary or sometimes panicled flowers, having the glandular ring membranaceous, and composed of five crenatures or lobes, and a two-lobed stigma.

*Tydaea*: erect herbs, with axillary or somewhat panicled flowers, having the glandular ring composed of five distinct glands, and a two-cleft stigma.

Of these new genera *Tydaea* is the most distinct and the most generally accepted.

**Achimenes** as above restricted, consists of two distinct series, one of which is well represented by *A. saccinea*, a species found in Jamaica and Central America. This plant has slender, erect, branching stems a foot or rather more in height, furnished with small ovate, acute, serrated leaves, and axillary one- or few-flowered peduncles bearing small scarlet, somewhat salver-shaped flowers, having a broadish cylindrical or somewhat swollen tube, nearly equal at the base, and a spreading limb of five rounded segments. The other series is represented by the Mexican and Central American *A. longiflora*, in which the stems are also erect, about a foot and a half in height, with ovate, acute, serrated leaves, and axillary peduncles supporting one large flower, of which the tube is elongated, slender, curved, and deflexed, scaccate at the base, and the limb very broad, plane, and lying in a direction oblique to the tube. The species are for the most part natives of Central America. They are not applied to any use, but are much prized for their ornamental properties. The mode of increase from the scaly tubers is very curious, each one of the scales, when separated, being capable of forming a new plant. The name *Achimenes* is also a synonym of *Arisaema*, a genus of the order *Scrophulariaceae*. [T. M.]

**ACHLAMYDEOUS.** Having neither calyx nor corolla, so that the essential parts of the flower are without a covering.

**ACHOTE.** The seeds of the Arnotto, *Bixa Orellana*.

**ACH-ROOT.** The root of *Morinda tinctoria*, used in India as a dye.

**ACHYRACHLÆNA.** The generic name of a Californian annual of the Composite family (*Compositæ*), nearly related to the better known and much prettier genera *Callichroa* and *Oxyura*, but differing from them in the nature of the pappus which crowns the cylindrical achenes, and consists of about ten very thin and membranous silvery scales, each about half an inch in length. The whole plant is clothed with soft white hairs, whence its specific name of *mollis*. The stems are seldom more than eight inches high, branched or simple, furnished with grassy leaves one to two inches long, and terminate in a single head of flowers half an inch across, with purple inconspicuous florets. The plant has also been called *Leptodactylus madrioides*. It has been cultivated at Kew. [A. A. B.]

**ACHYRANTHES.** A genus of *Amaranthaceae*, found in the tropical and sub-tropical districts of the Old World and consisting of erect, procumbent, or sometimes climbing trees and shrubs, many of them being troublesome weeds in cultivated grounds. The flowers are in loose spikes, hermaphrodite, and have three spinous bracts. The calyx consists of five, rarely four, sepals. The stamens, the same in number as the sepals, are united at their bases into a cup. The one-celled ovary contains a single

ovule, and has a simple style, and capitate stigma. The leaves are opposite. *A. aspera* and *fruticosa* are administered in India in cases of dropsy; *A. globulifera* is used in Madagascar as a remedy for erythema. Upwards of thirty species have been described. Though natives of the Old World, three or four species have been accidentally carried to the United States, where they have rapidly spread, becoming perfectly naturalized. [W. C.]

**ACHYROPHORUS.** A genus of annual or perennial herbs belonging to the Chicory group of the Composite family, and only distinguished from *Hypochaeris* by the feathery pappus-hairs being in a single instead of a double series. Of about twenty-five species four are S. European and Altasian; and one of these, *A. maculatus* is also common to Britain, but usually placed in *Hypochaeris* in our floras. The remainder are entirely S. American, and chiefly extend from Chili southwards. A few, found in the Andes at elevations of 10,000 feet and upwards, are neat little stemless plants, with a rosette of linear or lance-shaped toothed or entire leaves, and nestling in their midst a large and handsome yellow flower-head often more than an inch across. One of this set, *A. sessiliflorus*, is called in N. Granada *Chicoria de la tierra Caliente*; and, according to Purdie, a decoction of its thick white tapering roots is employed in affections of the chest. In those species found at low elevations, the root-leaves are spreading, entire and grassy, or pinnatifid like those of our hawkbits (*Leontodon*), their surface smooth or hairy; the yellow flower-heads single on the ends of unbranched stalks, or the stalks branching and furnished with leaves at the points of forking. *A. apargioides* and *A. Scorzonera* are known in Chili as *Escorzonera*, and their tapering roots are eaten for their refreshing and purifying qualities, as those of the Spanish *Scorzonera* (*Scorzonera hispanica*) are in this country. [A. A. B.]

**ACIANTHUS.** A genus of Australian terrestrial Orchids with solitary heart-shaped leaves and erect racemes of small green or dull purple flowers. They inhabit shady or damp places, and represent in the southern hemisphere the *Malaxis* and *Liparis* of the northern.

**ACICARPHA.** A genus of *Calyceæ*, comprising seven species, all of them found in the provinces bordering on the river Plate. They are small herbs with toothed or entire leaves, and lateral or terminal heads of flowers which are enclosed in a spiny involucre. In general they are found in saline or rocky soils, and may be considered as mere weeds. They do not appear to be applied to any useful purpose. *Acicarpha* embraces most of the members of the family found on the eastern side of the Cordillera. A name very similar to this, *Acicorpha*, has by mis-spelling been given to *Acarpha* in some books. [A. A. B.]

**ACICULA.** A bristle. The bristle-like abortive flower of a grass.

**ACICULAR.** Shaped like a needle.

**ACICULATED.** Marked by fine impressed lines, as if produced by the point of a needle.

**ACIES.** The edge of anything. The angles of certain stems.

**ACINACIFORM.** Scimitar-shaped; that is, curved, rounded towards the point; thick on the straighter side, thin on the convexity.

**ACINETA.** Noble epiphytal Orchids from Central America, with angular pseudobulbs, membranous ribbed leaves, and large fragrant fleshy flowers in pendulous or occasionally erect racemes: some brownish-purple, others more or less yellow. The genus was founded upon the *Anguloa superba* of Humboldt and Bonpland, whose artist imagined the great drooping raceme to be erect, and otherwise misunderstood the true structure. Several species are known, but they are not very well distinguished; in all the lip is united to the column by a solid immovable concave base, is three-lobed in various ways, and is furnished with a singular fleshy appendage rising from the middle in the form of a truncated body or of a mere horn. The species mentioned in books are *A. Humboldtii*, *Barkert*, *chrysantha* (alias *densa*), *Warszewiczii*, *erythroxantha* (alias *chamaecynoches*), *sella turcica*, and *cryptodonta*, all fine plants, and with the exception of *sella turcica*, all in cultivation.

**ACINODENDRON.** A genus of Gronovius now reduced to *Sagraea*, and supposed by De Candolle to be the same as *S. guadalupensis*.

**ACINUS.** A bunch of fleshy fruits, as of currants or grapes. Now confined to the berries of such bunches.

**ACIS.** A small genus of bulbous plants, belonging to the order *Amaryllidaceae*, and separated from *Leucojum*, from which they are distinguished by having a filiform style, and fleshy angular seeds. Both have a bell-shaped perianth, consisting of six nearly equal divisions, six stamens inserted in the epigynous disk, and an inferior three-celled ovary, containing numerous ovules. The species referred to *Acis* are plants of Southern Europe and Northern Africa, and are pretty subjects for bulb gardens. *A. rosea*, one of the neatest species, has a small round bulb, narrow blunt linear green leaves, and from one to three one-flowered scapes, blooming in succession. The flowers pendent, pale rose-coloured. The other species are *A. autumnalis* and *A. grandiflora*. [T.M.]

**ACKAWAI NUTMEG.** The fruit of *Acrodictidium Camara*.

**ACKROOT** or **AKROOT.** An Indian name for the Walnut.

**ACLINIA.** A supposed genus of Indian

Orchids founded by Griffith upon monsters of certain species of *Dendrobium*, in which regularity in the parts of the flower is substituted for their customary irregularity; the lip resembling the sepals and petals, and the column being triandrous, or nearly so. Five cases of the kind are recorded by Lindley, in the *Journal of the Linnean Society* (August 1856).

**ACOCANTHERA.** *Lycium cinereum*.

**ACONIOPTERIS.** A group of the *Acrosticheae*, in which the parallel veins of the fronds are angularly united near the margin. It is now included in *Olfersia*. [T.M.]

**ACONITE.** *Aconitum*. — WINTER. *Eranthis hyemalis*.

**ACONITUM.** An important genus belonging to the order *Ranunculaceae*, and botanically characterised by the calyx being not of a green colour, but blue or yellow, of five pieces, the upper of which is convex, and in form like a helmet. Within this are concealed two singularly shaped petals, formerly considered to be nectaries; the form of these bodies is somewhat like that of a hammer. There are also three other petals, very small and inconspicuous, though occasionally they also become hammer-shaped, like the two upper ones. The stamens are numerous; and the fruit consists of from three to five follicles. The plants constituting this genus are found in Europe and Northern Asia, and a few are natives of North America. One species, *A. Napellus*, is said to have been found wild in Britain, but this is open to grave doubts. All the plants of this genus possess virulently poisonous properties; the roots of some of the Indian species produce the Bikh poison of Nepal, one of the most dangerous of poisons. The roots of *A. ferox* (supposed to be a variety of *A. Napellus*) are used in the northern parts of Hindostan for poisoning arrows, with which tigers are destroyed. A tiger shot from a bow in Assam was found dead at only sixty yards from the spot, so soon did the poison take effect. Several kinds are commonly cultivated in gardens, especially *A. Napellus*, the fleshy roots of which have been occasionally used by mistake for horse-radish, and produced fatal results. This plant has a stem about three feet in height, with dark green glossy leaves, deeply divided in a palmate manner; the flowers are placed in erect clusters, and are of a dull blue colour. The roots, or more properly rootstocks, are of a tapering form, of a dark brown colour externally, and white internally; the younger roots, which are placed on either side of the older one, are of a lighter colour. The taste is bitter at first, but after a time numbness and tingling of the lips and tongue are perceived. The root has none of the acidity or pungency that fresh horse-radish possesses. The two plants are so dissimilar that it would seem impossible so terrible a mistake should be made, but it has generally arisen from taking the root of the

aconite when the leaves and flowers, which are so unmistakable, have died away. The rootstock of the horse-radish is much larger than that of the aconite, not of a tapering form, dirty yellow externally, and the top or crown marked with transverse scars, indicating the position of the old leaves; its

*Aconitum Napellus*.

odour and taste are at first pungent and acrid. The venom of the aconite appears to depend upon the presence of an alkaloid called Aconitina, which is so extremely poisonous that so small a dose as one-fiftieth part of a grain has wellnigh produced fatal results. A tincture of aconite root, or a solution of the alkaloid, is occasionally used with much success as an application to relieve rheumatic pains, but it should be employed with the greatest caution.

*Aconitum variegatum* is also commonly cultivated; it has, as its name implies, flowers variegated with white and blue.

*Aconitum Lycoctonum*, or Wolfshane, is a common plant in the Alps of Switzerland and Styria. Its leaves are palmate and

*Aconitum Lycoctonum* (flower).

hairy, of a dull yellowish green. Its flowers, which are borne in slightly branching clusters, are of a dull yellowish colour, and the shape of the upper sepal is that of an extinguisher, with a thick rounded

knob at the extremity. This species does not possess such virulent properties as the others. [M. T. M.]

**ACONTIAS.** A genus of plants so named in allusion to the spots on the stem, which resemble those of a species of serpent so called. The genus belongs to the *Caladium* tribe of the *Arum* family, and has tuberous rootstocks, lobed pedate leaves, green erect spathes, enclosing a spadix or fleshy spike, with female flowers at the lower portion, and male flowers at the upper. The species inhabit Brazil. [M. T. M.]

**ACORE ODORANT.** (Fr.) *Acorus Calamus*.

**ACORIDIUM.** A genus of caespitose plants, natives of Manilla. They have slender stems, sheathed at the base, and bear dioecious flowers in a linear spike. They are too little known to refer them satisfactorily to their position, although they seem to be allied to *Burmanniaceae* and *Xyridaceae*. [W. C.]

**ACORN.** The fruit of the Oak or *Quercus* family. —, **SWEET.** The fruit of *Quercus Ballota*.

**ACORUS.** The name of a genus of plants referred by some to the *Araceae*, and by others to the *Orontiaceae*. The most interesting plant of the genus is *Acorus Calamus*,

*Acorus Calamus*.

or Sweet Flag, a plant apparently known to the Greeks, though not to be confounded with the *Calamus aromaticus*, which, according to Boyle, was a species of grass. The Sweet Flag grows in ponds, by the banks of rivers, and other wet places in England

It is also found in the cooler parts of Europe, of India, and of North America. From the lower part of the thick jointed stem or rhizome, the plant sends down numerous roots, while from the upper surface it pushes upwards a number of lance-shaped leaves from two to three feet in length, sheathing at the base, also a long leaf-like stalk, from one edge of which, a foot or more above the rootstock, issues a spike of densely packed greenish flowers, each provided with a perianth of six pieces, enclosing six stamens and a three-celled ovary with a sessile stigma. All parts of the plant, but especially the rhizome, have a strong, aromatic, and slightly acrid taste; hence it has been used as a stimulant and mild tonic in medical practice, especially in some kinds of indigestion, and is said to be useful in ague. The rhizome is also used by confectioners as a candy, and by perfumers in the preparation of aromatic vinegar and other perfumed articles. *A. gramineus*, a much smaller plant, is sometimes cultivated in gardens. The Hindustani name is Butch; the Tamil name Vasa-mamba. [M. T. M.]

The *Acorus Calamus* imparts at once an aromatic taste, and an agreeable bouquet, to liquids in which it is infused. Professor Johnston states, in his *Chemistry of Common Life*, that it is used by the rectifiers to improve the flavour of gin, and is largely employed to give a peculiar taste to certain varieties of beer. According to the same authority, the London market used to be principally supplied from the rivers of Norfolk: as much as 40℥ having been sometimes obtained for the year's crop of a single acre of riverside land, on which it naturally grows. [T. M.]

**ACOTYLEDONS.** A name often applied to *Cryptogams*, or flowerless plants, in consequence of their reproductive organs or spores, when germinating, having no seed-leaves or cotyledons. There is, however, no rule without an exception, and some *Lycopods* present when young something very like cotyledons. Though *Cryptogams* have no true cotyledons, their spores produce, mostly by cell-division, a mass of threads, a leafy expansion, or a solid body, to which the name of false cotyledons pseudo cotyledonal has been given, and such productions, as the false cotyledons of mosses for example, have often been considered as distinct plants, belonging to a distinct natural order from the parent plant. Under this name are included all those plants called by Linnaeus *Cryptogamia*, because he was unable to discover their organs of fertilisation, if they had any. They comprehend Sea-weeds, Fungi, Lichens, Mosses, Ferns, and their allies: which see. It is now known that all are multiplied by a sexual apparatus in structure wholly different from that of phanogamous plants, but in function the same. One very great peculiarity is that in the majority of the orders a true locomotive action is observable in the matter emitted by the male organs; and that in the higher orders, that is to

say in Ferns, *Lycopods*, and *Horsetails*, the plant, properly so called, does not proceed directly from the spore or seed, but from a rudimentary intermediate organ, called prothallium, on which the organs of fertilisation are formed, those organs not producing a spore or seed, but the very plant itself.

**ACOTYLEDONOUS.** Having no cotyledons, as in *Cuscuta*. In systematical botany, applied to spore-bearing plants which do not produce cotyledons; also to spores themselves, which are embryos without cotyledons.

**ACOUCHI RESIN.** The inspissated juice of *Ictou heterophylla*.

**ACRADFNIA.** A plant found wild in the neighbourhood of Macquarrie Harbour, Tasmania, is the type of this genus of Rutaceous plants of the tribe *Bor-nia*, the distinguishing characters of which are the following:—parts of the flower in fives; stamens five, not united together, perfectly smooth; anthers smooth, not provided with any appendage; ovaries adhering closely together, and everywhere clothed with a dense woolly covering, except that each bears at its summit a small gland, whence the name of the genus. The endocarp has been described as not separating, but the only fruits known are open, and have already shed their seed; and on comparing them with other genera in a similar state, Mr Benham concludes that, as usual in the tribe, the endocarp has been cast with the seed. *A. franklinia*, the only species, named after Lady Franklin, is a shrub now in cultivation at Kew, with opposite terete leaves, which are thick, very rough and harsh on the upper surface, smooth on the under surface, and fragrant. [M. T. M.]

**ACRÆA.** A small genus of terrestrial Orchids with fleshy fasciculate roots, and close racemes of yellowish, downy flowers. In general aspect the species resemble the European *Spiranthes*. The three or four that are described come from Central America.

**ACRAMPHIBRYA.** Plants that grow both at the point and along the sides, as endogens and exogens.

**ACRIOPSIS.** In Burmah, Borneo, and the Malay Archipelago, are found several epiphytal Orchids with small reddish paniculate flowers, having their lip united firmly to the front of the column, from which it projects at right angles, in addition to which the column has two glandular arms, and is extended behind into a hood covering the anther. They belong to the van-deous sub-class, and are nearly related to the South American genus *Asparia*. Three or four species are known, of which two, *A. densiflora* and *picta*, have been cultivated. Beyond the very curious structure of the parts of fructification, they have little to recommend them to notice.

**ACROBRYA.** A term used by Endlicher, synonymous with *ACROGNA*. [M. J. B.]

**ACROCARPI.** A division of mosses containing those species in which the female fruit terminates the branches. Unfortunately even in the same genus, as *Pisidens*, species with lateral and terminal fruit occur, so that the distinction is not without grave exceptions. [M. J. B.]

**ACROGARPIDIUM.** The plants constituting this group of *Piperaceae* are now, by Casimir De Candolle, included in the genus *Peperomia*, from which they differ in habit and in the pseudo-pedicellate fruit. They are for the most part creeping plants, growing upon trunks of trees or mossy banks, with hairy or smooth, alternate roundish or kidney-shaped leaves, which have three or five prominent nerves; the flowers are placed in rings on long-stalked catkins with somewhat fleshy bracts; they have two distinct stamens, a simple stigma crowning the stalkless ovary, which latter ripens into a fruit so contracted at its base as to give an appearance as if it were placed on a stalk. They are natives of tropical America and the West Indies, and partake in some degree of the general cordial properties of the family to which they belong. *A. hispidulum* is made use of in the West Indies as a bitter and stomachic. Several kinds are cultivated in stoves as objects of curiosity or of botanical interest rather than for their beauty. They are best known under the old name of *Peperomia*. [M. T. M.]

**ACROCHAENE punctata.** An epiphytal orchid from the Sikkim Himalaya, where it was found by Dr. Hooker at the height of 4,000 feet above the sea. It has an ovate pseudo bulb, a long solitary coriaceous leaf, and an erect radical inflorescence. The flowers are straw-coloured, dotted with crimson. It is nearly related to *Scempia*, with which it agrees in having a couple of long taper caudicles for the pollen masses.

**ACROOLINIUM.** A beautiful genus of annual Composites, at present represented in our gardens by the *A. roseum*, a species introduced from the Champion Bay district, Western Australia. Its flower-heads resemble those of the well-known *Rhodanthe Manglesii*, but are larger, and the habit of the plant is entirely distinct. It produces numerous erect unbranched stems a foot or more high, the primary one emitting two opposite shoots from its base, each of which in its turn throws out two additional ones, which again become the parents of others, until the plant assumes a bushy character. The stems are clothed with numerous linear, smooth, pointed leaves, and bear at the summit a single handsome flower-head an inch and a half in diameter, consisting of a bright yellow disk of tubular florets, surrounded by a many-leaved, imbricated involucre, the innermost leaflets of which have spreading rose-coloured tips, presenting, as in *Rhodanthe*, *Helichrysum*, and other allied genera, the appearance of ray florets. The fruit, or, as it is popularly but incorrectly termed, the seed, is clothed with

snow-white silky down, and is surmounted by a pappus of from fifteen to twenty feathery hairs or scales, flattened and connected at their base, and tipped with a yellow tassell-like brush, by which characters the genus is chiefly distinguished. The yellow colour of the disk is due less to the colour of the florets themselves than to the brush-like tips of the pappus hairs, which under a lens are very interesting objects. Four other species occur in the same locality, but do not appear to have been yet introduced. [W. T.]

**ACROCOMIA.** The name given to a genus of Palms, in allusion to the elegant tufts of leaves at the summit of the stem. One species, *A. sclerocarpa*, grows almost all over South America, occurring in dry soil, rarely in woods. The tree belongs to the same tribe as the Cocoa-nut Palm; its trunk rises to twenty or thirty feet in height, and is sometimes swollen in the middle; the leaves are from ten to fifteen feet in length, pinnate, with from seventy to eighty leaflets on each side. The young leaves are eaten as a vegetable. It is cultivated in our hothouses. [M. T. M.]

**ACROGENS.** A large and most important division of **CRYPTOGAMS**, distinguished for the most part from **THALLOGENS**, as **FUNGUSES**, **SEAWEEDS**, and **LICHENS**, by their herbaceous growth, the presence of leafy appendages which are frequently furnished with stomates, the different mode of impregnation, and the presence of vascular tissue. A few acrogenous Liverworts have the habit of Lichens, but differ totally in structure.

The most important distinction, however, undoubtedly is that the impregnation takes place somewhat after the manner of **PHANOGAMS**, by an impression made upon the contents of the embryonic sac, and not upon the spore itself, as is decidedly the case amongst **Thallogens** where the mode of impregnation has been ascertained, as in *Alga*. In *Characae* alone the spore seems to be immediately impregnated, though even in this case it is uncertain whether impregnation does not take place before the spore is perfected.

In Mosses, Liverworts, and Ferns, the spore after germination produces at first either a web of threads, a solid mass, or a membranous expansion (*prothallium*). In the two former a distinct plant arises from the threads, with frequently symmetrical leaves, and on these plants urn-shaped organs are produced (called *archegones*) analogous to pistils, which contain at their base a cell which, after impregnation, produces the proper fruit. In perennial species a fresh crop of archegones may be produced in two or three successive years, which require a distinct act of impregnation for the development of the capsules. In Ferns and their allies, on the contrary, the archegones give rise to a new plant, which for one or for many successive years produces a fresh crop of fruit without further impregnation. The result of impregnation in the two cases, then, is quite

different. In Mosses the whole plant is, as to function, a prothallium; in ferns, merely the membranous expansion immediately produced on the germination of the spores. Further details may be reserved for each successive group. In those species of Fungi, as *Puccinia*, *Podisma*, &c., where a prothallium is produced, it has the nature of a spore, and germinates in the same manner.

As regards the tissues, it may be observed that the stem of many acrogens contains distinct vascular tissue. In *Jungermannia*, where such tissue is rare elsewhere, it almost universally accompanies the spores. In Mosses, as in *Sphagnum*, there are sometimes distinct spirals in the cells of the leaves. The vascular tissue in most of the higher cryptogams is scalariform; but in *Isaetes* and *Equisetum* it is annular, with transitions to short spirals, while in *Selaginella* and *Lycopodium* there is a transition from short spiral and reticulated cells to elongated cells, which may be called spiral vessels. In the stem of *Sphagnum* there is tissue closely resembling the glandular tissue of conifers. The spiral coats of the spores in *Equisetum* will be noticed hereafter. The impregnating bodies or spermatozooids have always flagelliform appendages, sometimes much more highly developed than in the spermatozoa of animals. The principal divisions of acrogens are:

1. CHARACEÆ. Spores solitary.
2. RHOCHACEÆ. Capsules valveless, without spiral cells or elaters.
3. MARCHANTACEÆ. Capsules dependent, containing elaters.
4. JUNGERMANNIACEÆ. Capsules erect, containing elaters.
5. MUSCI. Capsules mostly valveless, without elaters.

In these five orders the archegones give rise to the capsule.

6. FILICES. Capsules mostly with an elastic ring, but sometimes densely crowded and ringless.
7. OPHIOGLOSSACEÆ. Capsules ringless, bivalvate.
8. EQUISETACEÆ. Capsules dependent. Coat of spores spiral.
9. MARILLACEÆ. Capsules multilocular.
10. LYCOPODIACEÆ. Capsules axillary, unilocular.

In these five orders the spores produce a prothallium bearing archegones which yield new plants and not capsules. For further details see *Berkeley's Cryptogamic Botany*, p. 481. [M. J. B.]

**ACROGLOCHIN.** A genus containing only a single species, *A. chenopodioides*, from Nepal. It has been referred by some to *Salsolaceæ*, because of the horizontal position of the seed, as in *Chenopodium*; but the dehiscence of the utricle seems to separate it from the true *Salsolaceæ* and join it to the *Amaranthaceæ*, with which, however, it does not perfectly agree, for in this order the seeds are vertical. It in fact occupies

a position equally related to both these orders. The flowers are small, sessile, in axillary cymes. The calyx consists of five equal erect sepals. There are two stamens, and a unilocular ovary with a single ovule. The leaves are alternate, unequally dentate, and strongly reticulated below. [W. C.]

**ACROLASIA.** A genus of Chilian *Loasaceæ*, now referred to *Mentzelia*, from which it differs in having a definite number of stamens (ten), white flowers, and sinuate-pinnatifid leaves, which are opposite below and alternate above. [W. C.]

**ACRONIA.** A spurious genus of Orchidæ, now reduced to *Plourothallis*. The only species was *A. phalangifera*, which proves to be identical with *Plourothallis Mathewii*.

**ACRONYCHIA.** A genus of rue-like plants (*Eutaceæ*), distinguished by a short four-parted calyx, four petals, eight stamens inserted on a disk; style short; stigma capitate, four-lobed; fruit berry-like, four-celled, each cell containing one seed. As recently defined, it includes De Candolle's genus *Cyminoesma* (which see), and contains about fifteen species, extending over tropical Asia, and the islands of the S. Pacific, to New Caledonia and New Zealand. The flowers of *A. Cunninghamii* have a perfume like those of the orange. [M. T. M.]

**ACROPERA.** A genus of Mexican and Central American Orchidaceous plants, consisting of about four species, growing on the bark of trees. They have the habit of *Maxillaria*, with fleshy pseudo-bulbs and a drooping radical inflorescence. Their name, which signifies a pouch at the point, was given them in consequence of there being a sac at the end of their labellum. The flowers are of some dull yellowish colour, with very small misshapen petals. The genus is very near *Gongora*, to which it is reduced by Reichenbach.

**ACROPHORUS.** A genus of polypodiaceous Ferns of the group *Cystopteridaceæ*, distinguished by having its globose patches of fructification, situated mostly at the tips, rarely axillary in the forks of the veins, these sori being covered by suborbicular indusia affixed by their posterior side. They form a small genus, serving to unite the *Davallia* with the *Cystopteridaceæ*. The plants have creeping rhizomes, and very elegant membranaceous, pinnate or decompound, free-veined fronds, of which the divisions are either equal-sided or dimidiate. There are about a score of species, including those referred sometimes to *Leucostegia* and *Odontoloma*. The larger proportion of these are natives of India and the East. [T. M.]

**ACROPHYLLUM.** A genus of *Omeiaceæ*, founded upon a Tasmanian plant allied to *Weinmannia*, but distinguished by the absence of a disk in the flowers. *A. venosum* is a small erect shrub with evergreen leaves placed in whorls of three; they are nearly sessile, oblong, cordate, acute, serrated, and smooth; the stipules are small and membranous; and the flowers are small, white tinged with red, in dense

axillary clusters on the upper part of the stem and branches. Above the flowers there is a terminal tuft of leaves, from which the genus takes its name. The sepals and petals are five each, and stamens ten. It was introduced into this country in 1836, and forms a very striking and handsome greenhouse shrub. [J. T. S.]

**ACROPTERIS.** A name sometimes given to *Asplenium septentrionale*, and a few other asplenoid ferns. [T. M.]

**ACROSPIRE.** The first leaf that appears when corn sprouts. It is a developed plumule.

**ACROSTICHEÆ.** A section of polypodiaceous ferns, in which the sori occupy almost or quite the whole fructiferous surface, and are not confined to distinct and determinate points of the veins. [T. M.]

**ACROSTICHUM.** A genus of polypodiaceous ferns, typical of the group *Acrosticheæ*, with which, in the wider sense, it is synonymous. As restricted by modern pteridologists, the name is chiefly confined to a somewhat variable subaquatic tropical fern found in different parts of the world, which is distinguished by having the veins of its fronds uniting everywhere in a close network of small meshes, and by the lowermost leaflets or pinnae being sterile, and the upper ones fertile. The fertile parts, both in this genus and the rest of the *Acrosticheæ*, are entirely occupied by the densely packed spore-cases, which thus form universal or shapeless masses, without any special covering or indusium. The typical species is *A. aureum*, which, in one or other of its forms, is found in the West Indies, South America, Australia, the Pacific Islands and Eastern Archipelago, India, Mascaren Islands, Madagascar, South Africa, and Tropical Western Africa. It is a tall-growing plant, eight to ten feet high, with a thick rhizome or rootstock, and bold pinnated fronds, the upper pinnae of which are smaller, and clothed with the dense mass of confluent spore-cases. The plant is generally found near the sea, in morasses or moist situations. There are very few other species retained in the genus, and these mostly of doubtful character. [T. M.]

**ACROTOME.** A genus of *Labiata*, containing three species, natives of Southern Africa. They are shrubs or herbaceous plants, with small opposite leaves. The flowers are in dense verticillasters in the axils on the upper portion of the stem. The calyx consists of a campanulate tube with ten nerves and five or ten teeth. The tube of the corolla is scarcely longer than the calyx; its upper lip is erect, entire, and slightly arching, the lower tri-lobed, the middle lobe being largest. The stamens and style are included. This genus is nearly related on the one hand to *Leucas*, and on the other to *Marrubium* and *Sideritis*, but it is distinguished from all of them by its distinctly one-celled anthers. [W. G.]

**ACROTRICHE.** A genus of *Epicridaceæ*, found in the eastern and southern portions

of Australia and Tasmania, and distinguished by having a bi-bracteate calyx; a funnel-shaped corolla, the segments of which are clothed at the apex with deflexed hairs, and five slightly exserted stamens, which are shorter than the lobes of the corolla. The fruit is a depressed globose berry. They are shrubs of dwarfish habit, the branches usually divaricate, and clothed with scattered ovate or lanceolate leaves. The flowers grow in short lateral or axillary spikes, and are white or paired. The name of *Fraxelia fasciculiflora* has been proposed for *Acrotriche ramiflora*. [R. H.]

**ACTÆA.** A genus of Ranunculaceous plants so called from the resemblance borne by their leaves and fruit to those of the elder, in Greek *akte*. The British species, *A. spicata* Baneberry, is rare, being found only in bushy, mountainous limestone districts in the north of England. It bears its flowers, which are white slightly tinged with blush, in a spike. The berries are black and poisonous. The root has been used in nervous disorders, but is said to be a precarious remedy. It is sometimes called Herb Christopher, a name also formerly given to the flowering fern, *Osmunda regalis*. It is indigenous to the greater part of Europe. Two American species are occasionally to be found in the gardens of the curious, introduced from their native country, where they are abundant in rocky mountainous districts, from Canada to Virginia, particularly about Lake Huron. These are considered valuable medicines by the natives, especially as a remedy against the bite of the rattlesnake; hence they are, with several other plants, sometimes known as the Rattlesnake herbs. [C. A. J.]

**ACTINIOPTERIS.** A genus of polypodiaceous ferns of the section *Asplenium*, and consisting of curious little plants like miniature fan-palms, by which appearance they may be known. The technical peculiarities of the genus among the *Asplenium*, consist in the simple, distinct indusia, free veins, and linear elongate sori, which are marginal on the contracted rachiform segments of the small tabelliform fronds. One of the species, *A. radiata*, is plentiful in Southern India; and both this and its ally, *A. australis*, occur in Africa. The former grows three to six inches high, and produces an erect tuft of fronds which have a roundish outline, and are divided inwards from the margin very much indeed like what occurs in the fan-palms. [T. M.]

**ACTINODAPHNE.** A name derived from Greek words signifying *ray laurel*, and applied to a genus of the Laurel family (*Lawraceæ*). The plants are Indian trees with alternate leaves, sometimes clustered or whorled, feather-nerved or somewhat palm-nerved. Flowers in clusters or tufts, the male and female sexes on different plants. The male flowers have nine fertile stamens, in three rows, those of the inner row having a gland on either side of its base. The style is thick, the stigma

disk-shaped, the fruit berry-like, placed in the cup-shaped tube of the calyx. [M. T. M.]

**ACTINOMERIS.** A genus of perennial N. American and Mexican herbs of the Compositæ family, closely allied to Sun-flowers (*Helianthus*), but differing in the compressed and winged,—instead of 4-sided and wingless,—achenes, which have a pappus of two smooth bristles. There are about eight known species, most of them tall branching herbs, with alternate or opposite ovate or lance-shaped serrate leaves, which are smooth or rough, often tapering to the base, and decurrent on the stem, thus giving it a winged appearance. The rayed flower-heads, disposed usually in a corymbose manner, are white or yellow, sometimes  $\frac{1}{2}$  inches across, and not unlike those of some species of *Coreopsis*. The generic name alludes to the fewness or irregularity of the rays. A number of the species is cultivated in collections of herbaceous plants. [A. A. B.]

**ACTINOPHLEBIA.** A small group of cyathaceous Ferns, now included in *Hemitelia*. [T. M.]

**ACTINOSTROBUS pyramidalis.** A small shrub from Swan River, belonging to the Coniferous order. The branches are three-cornered, and jointed like a *Callitris*, from which genus it differs in having six equal valves to its cones, and three winged seeds. It inhabits salt marshes.

**ACTINOTUS.** A genus of *Umbelliferae*, containing seven species, natives of the eastern districts of New Holland. It is nearly related to *Sanicula*, but differs from that and allied genera in having no petals. It is characterised also by a one-ovuled ovary, crowned by two styles; the fruit is ovate, villous, and marked with fine striæ. The leaves are alternate, petiolate, and deeply trisected. The umbels are simple and many-flowered, the flowers on short pedicels, and surrounded by a many-leaved large involucre, which gives the genus somewhat the appearance of belonging to the *Compositæ*. [W. C.]

**ACULEUS.** A prickle; a conical elevation of the skin of a plant, becoming hard and sharp-pointed: as in the rose.

**ACUMINATE.** A term applied to leaves or other flat bodies which narrow gradually till they form a long termination; if the narrowing takes place towards the base, it is so stated, e.g. acuminate at the base; if towards the point, the term is used without qualification.

**ACUTARI WOOD.** The aromatic wood of *Isca altissima*.

**ADA aurantiaca.** Under this name has been published a New Grenada epiphytal Orchid from the neighbourhood of Pimpona, at 8,500 feet above the sea. It has closely packed bright orange-coloured flowers, with much the same structure as *Brassia*, except that the lip is firmly consolidated with the base of the column.

**ADAM and EVE.** *Aplectrum hyemale*.

**ADAMS NEEDLE.** The vulgar name for *Fucca*.

**ADAMITA.** A genus of the order *Sarifragaceæ*, related to *Hydrangea*, found in India, China, and other eastern countries. It has a short five-toothed calyx, a five to seven-petaled corolla, ten to twenty stamens, and a half-inferior ovary becoming a berry, which is many-seeded. *A. versicolor*, one of the most beautiful of the reputed species, is a native of China, and forms a dwarf smooth-branched shrub, furnished with largish opposite leaves, and flowers collected into a pyramidal panicle, nearly a foot in diameter; they are each six or seven-petaled, forming a pointed star, and while in bud are whitish, but they gradually change to purple and violet; they have twenty stamens. The berries are blue. Mr. Benthams unhesitatingly unites, as slight varieties only, the three supposed species of this genus. [T. M.]

**ADANSONIA.** This genus belongs to the natural family *Bombacææ*. The *Adansonia* has been considered the largest tree in the world, but it must now give place to the Mammoth tree of California, and the Australian Eucalypts. Its height is from 40 to 70 feet, and not at all in proportion to the size of its trunk, which sometimes attains the great diameter of 30 feet. It soon divides into branches of great size, which bear a dense mass of deciduous leaves, somewhat like those of the horse-chestnut. The flowers are large, white, solitary, and pendent on long stalks, and when expanded are about 6 inches across. The fruit is an oblong woody capsule, covered with a short down, and from 8 inches to a foot and a half long, in appearance somewhat like a gourd; internally, it is divided into 8 or 10 cells, each cell filled with a pulpy substance in which the seeds are immersed.

*A. digitata*, the Daobab, Ethiopian Sour Gourd, or Monkey-bread, is a native of many parts of Africa. It has been found in Senegal and Abyssinia, as well as on the west coast, extending to Angola, and from thence across the country to Lake Ngami. It is cultivated in many of the warm parts of the world. It has been called 'the tree of a thousand years,' and Humboldt speaks of it as 'the oldest organic monument of our planet.' Adanson, whose name the genus bears, and who travelled in Senegal in 1794, has given an account of this tree. He made a calculation to show that one of them, 30 feet in diameter, must be 5,150 years old! He saw two trees, from 5 to 6 feet in diameter, on the bark of which were cut to a considerable depth a number of European names; two of these were dated, the one in the 14th, the other in the 15th century. In 1555, the same trees were seen by Thevet, another French traveller, who mentions them in the account of his voyage. Livingstone says of the tree, 'I would back a true *Mowana* (the name given to it in the neighbourhood of Lake Ngami) against a dozen floods, provided you do not boil it in

salt water; but I cannot believe that any of those now alive had a chance of being subjected to the experiment of even the Noachian deluge.'

The bark of the Baobab furnishes a fibra which is made into ropes, and in Senegal woven into cloth. The fibre is so strong as to give rise to a common saying in Bengal: 'As secure as an elephant bound with a baobab rope.' The wood is soft, and subject to the attacks of a fungus which destroys its life, and renders the part affected easily hollowed out. This is done by the negroes, and within these hollows they suspend the dead bodies of those who are refused the honour of burial. There they become mummies, perfectly dry and well preserved, without any further preparation or embalmment.' Livingstone speaks of a hollow trunk, within which 20 to 30 men could lie down with ease. The leaves pounded constitute *Lalo*, which the Africans mix with their soups, sauces, &c., not as a relish, but to diminish the excessive perspiration, and keep the blood in a healthy state. 'The pulp of the fruit is slightly acid, agreeable, and often eaten; and the juice expressed from it constitutes a drink which is valued as a specific in putrid and pestilential fevers. Owing to this circumstance it forms an article of commerce.' The ashes of the fruit and bark boiled in rancid palm oil are used as a soap by the negroes.

The only other species of the genus is *A. Gregorii*. It is a native of the sandy plains of N. Australia, and is known as Sour gum and Cream of tartar tree. It dif-

*Adansonia Gregorii*.

fers chiefly from *A. digitata* in its smaller fruit with a shorter foot stalk. The largest tree seen in Gregory's expedition was 85 feet in girth at 2 feet from the ground. The pulp of its fruit 'has an agreeable acid taste, like cream of tartar, and is peculiarly refreshing in the sultry climates where the tree is found. It consists of gum, starch, sugary matter, and malic acid.' [A. A. B.]

**ADDER'S MOUTH.** An American name for *Microstylis*.

**ADDER'S TONGUE.** The English name for *Ophitoglossum*. — **YELLOW.** *Erythronium americanum*.

**ADECTUM.** A synonym of *Dennstaedtia*, a handsome free-growing genus of ferns, related to *Dicksonia*. [T. M.]

**ADELASTER** (*Gr.* like something unknown). A name proposed for those garden plants which, having come into cultivation without their flowers being known, cannot be definitively referred to their proper genus. All *Adelasters* are therefore provisional names, to be abandoned as soon as the true names of the plants so called can be ascertained.

**ADENANDRA.** A genus of Rutaceous or rue like plants, so named on account of the presence of a small gland on the top of the stamens. They consist of small shrubs, natives of the Cape of Good Hope, and some of them are cultivated for the sake of their pink-coloured flowers. The genus is principally distinguished by its 5 sterile stamens, which are in form like the 5 fertile ones, but longer: both kinds tipped with a gland. The leaves are used for the same purposes as those of *Diosma* at the Cape. [M. T. M.]

**ADENANTHERA.** A genus of the *Poa* family (*Leguminosae*). The species are chiefly found in eastern India and the Malayan Islands, and one is wild in Madagascar. They are trees or shrubs, with bipinnate or compound leaves and spikes of small yellow flowers, the anthers of which are tipped with a stalked gland; and these gland-tipped anthers give rise to the generic name. *A. pavonina* grows to a great size in the East Indies, and yields a solid useful timber, called Red Sandal wood, a name which is also given to the wood of *Pterocarpus santalinus*. A dye is obtained by simply rubbing the wood against a wet stone; and this is used by the Brahmans for marking their foreheads after religious bathing. The seeds are of a bright scarlet colour, and are used by the jewellers in the East as weights, each seed weighing uniformly four grains. Pounded and mixed with borax, they form an adhesive substance. They are sometimes used as an article of food, and are frequently made into ornaments, such as bracelets, necklaces, &c. [A. A. B.]

**ADENOCALYMNA.** The name given to a genus of *Bignoniaceae*. The species are large climbers, and all of them natives of Brazil, where they scramble over trees, enlivening the forests with their clusters of bright-coloured yellow, orange, or pink flowers. Their stems are slender and often rough. Their leaves are ternate, or sometimes only binate; when this latter is the case, a tendril-like appendage takes the place of the third leaflet. Numbers of depressed circular glands are found on their surface, as well as on the calyx; and from this circumstance the genus receives

its name *Adenocalymna*, which is composed of Greek words signifying gland and covering. The flowers are borne on long racemes; they are trumpet-shaped, and, intermixed with them, are large bracts, which fall off early. Some of the species are cultivated in our stoves for their beauty. [A. A. B.]

**ADENOCARPUS.** This is a genus of the Pea family (*Leguminosae*), composed of plants which are most of them extremely handsome, from their bearing profuse racemes of yellow flowers. The genus only differs from that of the common English broom (*Genista*) in having pods covered with glands; whence its name *Adenocarpus*, which is derived from two Greek words signifying gland and fruit. They are found in the Pyrenees, the Sierra Nevada, and in other parts of southern Europe, but chiefly at high elevations. One species is found in Madeira, and a few in the Canaries. Mr. Bunbury, in writing on the botany of the Peak of Teneriffe, says: 'To the region of the heath succeed, as we ascend, that of the Codeso del Pico (*Adenocarpus frankenioides*). The limit of this plant is particularly well marked. For a little space it is intermixed with scattered and stunted bushes of the heath, but this soon thins out and disappears, and for miles the whole slope is covered with the *Adenocarpus* alone, as some of our commons and wastes in England are covered with furze. It is in general a low compact rigid bush, peculiar in its multitude of short lateral branches, and the minute closely-crowded grey-green leaves; by no means a handsome plant when out of flower; but here and there, in sheltered spots, it assumes the character of a little tree. It is one of the most eminently social plants in the world.' Several species are cultivated in gardens. [A. A. B.]

**ADENOPHORA.** A genus of plants allied to *Campanula*, and like it bearing bell-shaped flowers, the chief mark of distinction being that the style of the present plant is surrounded by a cylindrical gland, whence its name (from the Greek *aden*, a gland, and *phero*, to bear). The plants of this family are perennial, rarely biennial herbs, with erect stems, alternate or somewhat whorled leaves, which below are broad and stalked, but gradually becoming narrower as they ascend the stem. The flowers are blue, stalked and drooping, and for the most part are situated towards the top of the stem, where, in some instances, they form a spike or cluster, while in others they are few in number. Most of the species are natives of Siberia, China, and Japan. One species, *A. liliifolia*, or *A. suaveolens*, is found in many countries of eastern Europe, and occurs also in France, Hungary, and Candia. In this the flowers are numerous, sweet-scented, and disposed in a loose pyramidal panicle. The root is thick and esculent, as are those of some of the other species. All are elegant border flowers, and are, therefore, worth cultivating in gardens. [C. A. J.]

**ADENOPHORUS.** A small group of ferns, in which the sori are terminal on the free veins, the receptacle at the apex of the simple costa-like or central veins being dilated or obovate. The fronds are small, very elegant in character, and bear glands over their surface. The species are now referred to *Polypodium*. [T. M.]

**ADENOPUS.** A dioecious scandent genus of *Cucurbitaceae*, of four species, natives of Sierra Leone, Abyssinia, and West Tropical Africa. The leaves are three to five-lobed, with two glands at the apex of the petiole, except in *A. glandulosus*. The male flowers are racemose, have a tubular five-lobed calyx, a five-lobed rotate corolla, filaments free, inserted within the calyx tube, and three included anthers clustering in a cylindric column. The female flowers are solitary, large, white, and fragrant; the calyx-tube is not produced beyond the ovary, which is subglobose, with a short style, terminated by three broad stigmas. The fruit is many-seeded, spherical or broadly ovoid. [J. Br.]

**ADENOSMA.** A genus of *Acanthaceae*, containing eight or nine species, natives of Asia. They are annual herbaceous plants, having the odour of the Mints, with opposite leaves, and sessile flowers in the axils of the small leaves on the upper portion of the stem, so aggregated as to form a leafy spike. The genus is characterised by a five-partite calyx, a gaping corolla, four didynamous stamens, with anthers composed of two parallel cells. The long capsule is many-seeded. It differs from the allied genus *Libermarya* in the gaping corolla, and in the structure of the anthers. [W. C.]

**ADENOSTYLIS.** A genus of the composite family, comprising but few species. They are perennial mountain herbs, with alternate stalked, cordate, or reniform leaves, which are smooth, or covered with a loose white cotton. Their flower-heads are numerous in terminal compact corymbs, with florets of a purple or white colour. In appearance these plants are much like the common rotsfoot (*Thussilago Farfara*), but they differ from the rotsfoot in having all their florets fertile. They are all natives of mountain districts in southern Europe, the greater part of them being found in the Pyrenees, where they grow luxuriantly in stony places beside alpine rivulets. The leaves of *A. glabra* have been recommended in coughs. [A. A. B.]

**ADESMIA.** A large genus of the Pea family (*Leguminosae*), confined to the temperate parts of S. America. Commencing in the Bolivian Andes, they extend southward to Cape Horn; but are found in greatest numbers in Chili. They are annual or perennial; some of them shrubs four or five feet high, and most of them with alternate equally pinnate leaves terminated by a bristle. Their flowers are disposed in racemes at the apex of the branches, or solitary in the axils of the leaves, and are generally yellow with purple stripes. The pods are jointed, rough on

the surface, and sometimes beset with feathery bristles. One of the species, *A. aphylla*, has its leaves reduced to mere scales; and in another, *A. trifoliata*, they are not unlike those of the common wood sorrel. *A. balsamifera*, a Chilian species called Jarilla, is a plant of great beauty when in flower; it yields a balsam which has a very pleasant odour, perceptible at a great distance. This balsam is said to be of great efficacy in healing wounds. A few of the species have their abortive flower-stalks converted into forked spines. There are upwards of fifty species. [A. A. B.]

**ADHATODA.** A genus of Acanthaceous plants, consisting of herbs or shrubs with opposite leaves, and axillary spikes of flowers, each flower furnished with three bracts, the outer one of which is large and persistent, covering the calyx; the two inner ones smaller. The calyx is five-parted; the corolla two-lipped; the four stamens are inserted on the throat of the corolla; the anthers are two-celled, with a large connective, the lobes unequal, and the inferior ones often spurred; the filaments compressed, bent downwards; the style thread-shaped, bent downwards; and the capsule stalked, two-celled, four-seeded, bursting by two valves. *A. vasica*, the *Justicia Adhatoda* of Linnaeus, is a common plant in India; its wood is soft, and its charcoal is excellent for the manufacture of gunpowder. The flowers, leaves, root, and especially the fruit, are considered as antispasmodic, and are given in cases of asthma and intermittent fever. The word *Adhatoda* is a latinised form of the native Malabar or Cingalese name. [M. T. M.]

**ADIANTÆÆ.** A section of polypodiaceous Ferns, in which the receptacles to which the spore-cases are attached, are placed on the under surface of the indusium itself, so that the fructification is, as it were, upside down, and is hence said to be resupinate. [T. M.]

**ADIANTOPSIS.** A small genus of elegant polypodiaceous Ferns, of the section *Cheilanthes*, distinguished partly by their adiantoid aspect, but technically by having marginal punctiform sori terminal on the free veins, and covered by distinct orbicular indusia. The plants bear generally tufted stems, and small elegantly-divided fronds. The species are found in South America, the West Indies, and Africa. *A. radiata*, one of the best known of them, common in the West Indies and South America, grows about a foot high, from a tufted crown, the stipites shining black, and the fronds spreading out at top of the stipites into a radiate tuft of pinnate branches. The species are often seen in cultivation, on account of their small size and elegant character. [T. M.]

**ADIANTUM.** An extensive and much admired genus of polypodiaceous Ferns, typical of the group *Adiantææ*. The species are scattered nearly over the whole world, but are most abundant in tropical

countries. They have all black shining stipites, and mostly roundish or rhomboidal or lunately-curved pinnules, the fronds being very various in size and general character. The structure is very peculiar, unlike that of any other ferns. The sori are marginal, covered by indusia, which are either roundish and distinct, or become blended into a linear form, these two conditions respectively resembling the fructification seen in *Cheilanthes* and *Pteris*; but it is resemblance only, the fructification (spore-cases) being in the latter genera seated on the frond itself, and covered by the indusium, while in *Adiantum* they are not attached to the frond, but to the under side of the indusium, and are therefore turned upside down on to the surface of the frond. This structural peculiarity distinguishes *Adiantum* from all other ferns except *Hewardia*, which is known by having a reticulated venation, that of *Adiantum* being free. The genus is represented in the British Flora, by *A. Capillus-veneris*, the Maidenhair Fern, a very elegant plant, with a creeping scaly rhizome, and bipinnate fronds, the leaflets of which are between rhomboidal and wedge-shaped, margined with oblong sori, and more or less deeply lobed. This species is very extensively distributed in the temperate or tropical parts of Europe, Asia, Africa, and America, and not very materially varying in form, notwithstanding this wide range. Some species, as the *A. reniforme* of Madeira, have entire fronds; in others, as the *A. lunatum* of India, they are pinnate; not a few species are, like our native one, bipinnate; and numerous others are tripinnate, or still more divided. *A. pedatum*, a very beautiful North American species, which has the fronds pedate, the divisions pinnate, and the pinnules halved oblong and lunate, incised along the upper edge, is sometimes used in the preparation of capillare. The species are great favourites in both houses. [T. M.]

**ADLUMIA.** A climbing genus of Fumeworts, consisting only of the *A. cirræosa*, a pretty North American biennial, formerly known as *Corydalis fungosa*. It is distinguished from the other genera of the order by the permanent cohesion of its four spongy petals into one piece, and by a many-seeded pod, splitting, when ripe, into two valves. Its chief attraction consists in its delicate pale green triply pinnate foliage, the twining footstalks of which act as tendrils; the small flesh-coloured blossoms are freely produced, but possess little beauty. The plant neither climbs nor flowers till the second year. [W. T.]

**ADNATE.** Grown to anything by the whole surface; when an ovary is united to the side of a calyx it is adnate.

**ADONIS.** A small genus of Ranunculada, mostly European, comprising several popular border flowers, both annual and perennial. It is characterised by the absence of an involucre, and by having five sepals, a corolla of from five to fifteen

petals, and numerous dry ovate carpels, pointed with the style, and grouped in a short spike or head; all the species have the foliage cleft into numerous linear segments, and produce but a single flower at the summit of each stem and branch. Of the annual section, eight or ten species are described, but only two are to be found in general cultivation: *A. autumnalis*, and *A. autumnalis*, the former imperfectly established in England, both having small, deep crimson flowers, the petals in the latter much longer than the calyx, whilst in the former they scarcely exceed it. They are popularly known as Pheasant's Eye, and Flos Adonis. The perennial species are all showy, dwarf herbaceous plants, with black fascicled roots, and large glossy yellow flowers. The best and most commonly cultivated species is the *A. vernalis*, which is a very effective early or spring bloomer. [W. T.]

**ADOKA.** A small genus referred by Mr. Bentham to the *Caprifoliaceæ*, consisting of a single species, *A. Moschatellina*, the Tuberous Moschatel, found blooming in spring in woods and on shady banks in many parts of England, and extending through Northern and Central Europe and parts of Asia and North America, far into the Arctic regions. The genus is distinguished by bearing a calyx of two or three spreading lobes; a short-tubed corolla, with four or five spreading divisions; eight or ten stamens in pairs alternating with the divisions of the corolla, and inserted on a little ring at its base; three to five short styles united at the base; a three to five-celled ovary, with one ovule in each cell and maturing into a berry. The plant is a low herb, of four to six inches high, smooth, pale green, forming creeping half-buried runners, the leaves ternately divided, with broad deeply three-lobed segments, and the musky-scented flowers pale green in a little globular head at the top of the short leafy flower-stems. The upper flower in each head has generally a tetramerous arrangement of parts, two calyx lobes, four corolla lobes, and eight stamens; while the lateral ones have three calyx lobes, five corolla lobes, and ten stamens. The *Adoxa* has, until recently, been classed with the *Araliaceæ*. [T. M.]

**ADPRESSED.** Brought into contact with anything without adhering.

**ADELPHIA.** A fraternity—a Linnean term denoting a collection of stamens. *Monadelphia* = one such collection; *Diadelphia* = two such collections; and so on.

**ÆCHMEA.** A genus of *Bromeliaceæ*, having six-parted perianth, of which the three outer sepaline divisions are equal, and much shorter than the inner petaloid ones. The flowers have six stamens, and an inferior three-celled ovary containing numerous ovules, and becoming a sub-globose berry. The species are found in tropical America, often epiphytal on the trunks of trees in the dense forests. They have strap-shaped or sword-shaped leaves, some-

times spiny at the margin; and from the centre of these is developed the flower scape, which is branched in a panicled manner and bears numerous flowers. *Æ. discolor*, one of the most striking of the species, has broad recurved leaves, which are dull green above and purplish beneath. The panicle is longer than the leaves, of a scarlet colour in the upper part, bearing the flowers distantly spiked along the branches. The flowers are without bracteoles, in which respect it is peculiar. The calycine segments are oblique and obtuse, coral-red below, blackish above, the petaline ones twisted, purplish. The unexpanded buds have a most striking resemblance to the seeds of *Abrus precatorius*, commonly called crab's eyes, and sometimes strung as beads. [T. M.]

**ÆCHMOLEPIS.** A genus of *Asclepiadaceæ*, containing a single species, a native of Angola. It is a shrub with ternate leaves, glabrous above, hoary and reticulated beneath. It is characterised by its filaments being connate at their base and distinct above, by having its anthers cohering at the apex, though free from the stigma, and by its twenty granular pollen masses. [W. C.]

**ÆCIDIUM.** A genus of *Fungi*, comprising a large number of parasites, which grow upon the living parts of plants. The reproductive organs or spores are nearly globose, arranged in little necklaces, which radiate from a thin cellular base, and, as they easily break off, form a little dust-like heap, which is white, yellow, orange, &c., according to the species. The whole mass is surrounded by a membranous coat or peridium, which sometimes bursts irregularly at the tip, but more frequently splits into a number of nearly equal lobes, which curl back, and have a very pretty appearance under the microscope. They grow on the leaves, petioles, fruit, or young shoots, sometimes producing but little constitutional derangement, but occasionally causing the adjacent parts to swell, or producing great distortion, as in a species which attacks the shoots of elder in North America. Sometimes the whole appearance of the plant is altered, as in one which commonly attacks species of *Epilobium*; while, again, at times, particular leaves only are affected, as in the garden and wood anemone, where the outline is somewhat changed, and the substance is greatly thickened. Where the plant is only partially affected, the general health is not much impaired; but where the parasite is very vigorous, death may ultimately ensue. We are not aware that any species attacks our cereals. There has, however, been a very unjust charge brought against *Æcidium berberidis*, a beautiful species, which attacks the leaves, flowers, and young fruit of the berberry, as if it were the cause of mildew in wheat. Great, however, as are the changes which *Fungi* undergo occasionally in passing from one condition to another, there is not the slightest reason

for imagining that the *Æcidium* is a transitional state of wheat mildew. It has its own mode of propagation, and passes through nearly the same phases of vege-

*Æcidium tussilaginis*

tation as the mildew, without affording a suspicion that it is not a perfect plant. The whole story has no doubt arisen from the *Æcidium* being common on the herb-berly in hedges surrounding wheat fields; and there is reason to believe the report is true, that wheat has been especially mildewed in the neighbourhood of the *Æcidium*. The peculiar situation, however, may be equally favourable to either parasite; and it is to be observed, that mildew is peculiarly prevalent in districts where the herb-berly is unknown, except as a garden plant. *Æcidia* attack phænogamous plants of various kinds, but they are far less frequent on endogens than exo-gens. Species occur in all parts of the world, but are more common in temperate regions. See also *Barberi*. [M. J. B.]

**ÆGIALITIS.** A genus of *Plumbaginaceæ*, containing a small number of Australian and Indian undershrubs, with thick articulated stems, and alternate-stalked ovate or roundish leaves of leathery texture; flowers in spikelets, arranged in branched spikes; calyx tubular-cylindrical; petals small and white; styles quite free and glabrous with awl-shaped stigmas. The seeds of *A. annulosa*, which grows in mangrove swamps, are said to germinate while on the plant. [J. T. S.]

**ÆGICERACEÆ.** This name has been given by Blume to *Ægiceras*, viewed as the representative of a natural order containing no other genus than itself. It is, however, generally included in *MYRSINACEÆ*, which see.

**ÆGICERAS.** A genus of *Myrsinaceæ*, differing from all the other genera in that family by its follicular fruit. The species, of which there are five, consist of small trees, inhabiting swampy shores in the tropical parts of India, the Indian Archipelago, and Australia, where they form impenetrable thickets like the mangroves (*Rhizophora*), in consequence of their seeds

germinating while yet in the fruit, and sending down strong perpendicular roots into the mud, without separating from their parents. They have obovate entire dotted leaves, the upper surface of which is often covered with a saline incrustation, which, according to Blume, they secrete. Their flowers are white, fragrant, in terminal or axillary umbels; the flower-stalks articulated at the base. *A. majus* is the only vegetation to be seen for miles along the coast of Sumatra. [A. A. B.]

**ÆGILOPS.** A genus of Grasses allied to *Triticum*, or Wheat grass. It occurs wild in the south of Europe and parts of Asia. Botanists have recognised as many as three species; but from recent experiments in the culture of *Ægilops*, there is reason to believe, not only that all the so-called species are referable to one, namely, *Æ. ovata*, but that the *Ægilops* is, in reality, the plant from which has originated our cereal wheats. Upon this subject will be found an interesting paper, translated from the French, in the *Journal of the Royal Agricultural Society* (vol. xv), from which it would appear that M. Esprit Fabre, of Ayde, has made the *Æ. ovata* the subject of experiment, and that from it he obtained the form known as *Æ. trivoides*, the continued cultivation of which latter, for six years, resulted in the production of very respectable ears of wheat. The changes that occurred were a lessening in the numbers of the awns, and a gradual conforming of the chaff scales to those of wheat, a greater length and regularity of growth in the ear, an enlargement of the seed to that of the wheat, and a taller and more upright habit of growth of the whole plant. Both the experimental results, and the conclusions of M. Fabre have been doubted by some of the specific botanists, and we are, therefore, glad to have an opportunity of recording the result of our own experiments in this interesting matter. In 1834, we planted a plot with seed of *Æ. ovata*, from which was gathered seed for a second plot in 1855, leaving the rest of the first plot to seed itself, which it did, and came up spontaneously. This plot has since continued to bring forth its annual crop in a wild state, in which the spikes are short, and so brittle that they fall to pieces below each spikelet the moment the seed is at all ripe. The produce of the 1855 crop has, in the same manner, been cultivated year by year in different parts of the experimental garden of the Royal Agricultural College, and our crop for 1860 had many specimens upwards of two feet high, and with spikes of flowers containing as many as twelve spikelets. Our conclusions then are, that with us the *Ægilops* is steadily advancing; and we fully expect, in three or four years, to arrive at a true variety of cereal wheat. What too is confirmatory of this matter, is that the bruised foliage of the wild grass, and the cultivated wheat, emits the same peculiar odour, and, besides the *Ægilops*, is subject to attacks of the same species of parasites (blights),

our examples of this year being much affected with the rust (*Uredo rubigo*), mildew (*E. cinia graminis*), and others. These, it

*Eglisora*: — a *E. ovata*; b *E. ovata* triticoidea; c the same after four years' cultivation; d the same after five years' cultivation

would seem, are the effects of civilization; and it is not a little remarkable, that in this respect this grass should be so much like our field crops, which were particularly liable to blight in the straw and foliage during 1860. [J. B.]

**ÆGINETIA.** A genus of the Broomrape family (*Orobanchaceae*), found in India and the Islands of the Indian Archipelago. They are annual, leafless, parasitical herbs, growing on the roots of various grasses, their stems from three inches to a foot high, bearing a solitary terminal flower, and having at their base a few scales. The whole plant is of a brown colour, except the flower, which is large and tubular: the tube white, and the limb rose, or altogether purple outside, and the throat yellow. The calyx is one-leaved and cleft in front. A *radix*, prepared with sugar and nutmeg, is considered an antiscorbutic. [A. A. B.]

**ÆGLE.** The name of a genus of plants belonging to the Orange family (*Aurantiacae*). The fruit, known in India as the Bael fruit, is the product of *E. Marmelos*. In appearance it is much like the orange. The thick rind of the unripe fruit possesses astringent properties, on which account it is used in India in cases of dysentery and diarrhoea. The ripe fruit has an exquisite flavour and perfume. Not only the fruit, but other portions of the plant are used for medicinal purposes, and a yellow dye is prepared from the rind of the fruit. The genus is distinguished by its numerous distinct stamens from the Orange (*Citrus*), to which, in other particulars, it is closely allied. [M. T. M.]

**ÆGOCHLOA.** A group of dwarf, hardy annuals of the *Polemonium* family, chiefly Californian. Their tubular calyx, with unequal, rigid, multifid segments, and corolla with salver shaped limb, distinguish them from their near allies. The species have, for

the most part, pinnate or pinnatifid clammy foliage, more or less spinous, and small-clustered gills like flowers. None of them are remarkable for their beauty, and with the exception of *E. pungens*, are not known in British gardens. The species are referred by Dr Asa Gray to the section *Novaeboracensis* of the genus *Gilia*. By some authors they are classed under the genus *Novaeboracensis*, which is sometimes regarded as distinct. [W. T.]

**ÆGOPODIUM.** An Umbelliferous plant with smooth thrice-ternate leaves, unattractive white flowers, and an unpleasant odour when bruised: a common pest of orchards, shrubberies, and ill-kept gardens, where, by means of its creeping roots, or rather subterraneous stems, which are of rapid growth and singularly vivacious, it soon establishes itself when once admitted, and defies eradication, smothering all vegetation less rampant than its own, and disfiguring where it finds nothing to choke. Its old English names were Gout-wort or Gout-weed, Herb Gerard, Ash-weed, and English Master-wort. It was, as one time, accounted a specific for the gout, hence its specific name *Podagraria*; but though, like the rest of the umbelliferous tribe, partaking of aromatic properties, it is really of no more value in the pharmacopoeia than in the garden. Linnæus says it is eaten in Sweden, boiled for greens when tender in the spring. It is a native of the whole of Europe to Caucasus and Siberia. Gerard says of it: 'Herb Gerard's growth of itself in gardens without setting or sowing, and is so fruitful in its increase, that when it hath once taken root, it will hardly be gotten out again, spoiling and getting every year more ground, to the annoying of better herbs.' An Alpine species, which appears to possess all the bad properties of its congener, is found in Asia. [C. A. J.]

**ÆGOTOXICUM or EATOXICUM.** A genus doubtfully placed in *Euphorbiaceae*, and more recently in *Monmiaceae*. The species, *E. punctatum*, a native of Chili, is described as a sombre-looking tree, forming immense woods. The leaves are opposite, shortly stalked, oblong, and entire, the upper surface smooth, the under covered with rusty scales. The flowers are male and female, the males alone on one tree, and the females on another; they are disposed in axillary racemes. The fruit is a one-seeded drupe, about the size of a pea. Planks and beams are made of the wood; and the fruits are said to be a powerful poison to goats. [A. A. B.]

**ÆONIUM.** The plants that are comprised in this genus of *Cyrtaceae* are much more generally known as species of *Sempervivum*, from which, however, they differ in their seed-vessels being partially sunk in the receptacle, and not regularly opening by their ventral suture, but only at the base and back by an irregular tearing. *E. arborescens* is well known to gardeners as the Tree Houseleek; its loose panicles, with a profusion of clammy yel-

low blossoms, are very elegant. *Æ. tabulariformis*, as well as others of the genus, is remarkable for the stem being so contracted that the leaves are closely packed in flat rosettes. Like other succulent plants, their tenacity of life is remarkable. They are natives of the Levant, Madeira, the Canaries, &c. [M. T. M.]

**ÆQUALIS.** This term signifies equality or similarity in size, and is also used in the sense of uniformity; thus, an equal umbel, is an umbel of which the florets are all alike.

**ÆRANTHUS grandiflora**, is a Madagascar epiphytal orchid with distichous leaves, and large green solitary flowers at the end of weak, flexible scapes. It is sometimes seen in cultivation. From *Angrecum* it differs in having a lip articulated with the foot of the column.

**ÆRIDES.** A large genus of tropical Orchids, with distichous leaves, mostly channelled and unequally truncate, but sometimes terete. All the species inhabit the warmer parts of Asia. The flowers are usually among the largest of the order, of all tints except blue, and frequently extremely sweet. One of them, with small flowers, clings to the branches of trees in Sylhet with such long flat roots, resembling bands of a tape-worm, that it has gained the name of *Ærides tantale*. This is not in cultivation.

**ÆROCYSTS.** The air-cells of algae.

**ÆROPHYTES.** Plants growing wholly in the air; such as epiphytal orchids, many lichens, bromeliads.

**ÆRUA, or ARVA**, a genus of *Amaranthaceæ*, consisting of shrubs and herbaceous plants from Africa, tropical Asia, and probably Central America. The plants have a more or less white tomentose appearance. The leaves are alternate. The minute flowers are in dense terminal or axillary spikes, and are hermaphrodite, with three concave persistent bracts. The calyx consists of five nearly equal, erect, and hairy sepals; the five stamens are united into a cup at their base; the ovary is one-celled, with a single ovule in each cell; the fruit is a roundish utricle. Nineteen or twenty species have been described. The flowers of *Æ. tomentosa* are used in Egypt, under the name of Toorî, for stuffing mattresses. [W. C.]

**ÆRUGINOUS.** Verdigris-coloured.

**ÆSCHYNANTHUS.** A beautiful genus of tropical plants of epiphytal habit, belonging to the cyrtandrous group of the *Gesneraceæ*. The peculiarities of structure are a tubulous five-cleft equal calyx, a monopetalous corolla with a curved tube dilated at the throat, and a two-lipped spreading five-lobed limb; there are four didynamous stamens, and the ovary is surrounded by a fleshy hypogynous glandular ring. The species inhabit the tropical parts of Asia, and are among the most

gorgeous ornaments of hothouses in this country, many of them having been introduced to cultivation. They have mostly pendent stems, opposite fleshy leaves, and scarlet or orange-scarlet flowers. One of the finest species, *Æ. speciosus*, is of sub-erect habit, with ovate lanceolate acuminate fleshy leaves, and a terminal fascicle of from ten to twenty erect long-tubed flowers, of a rich orange-yellow below, passing into scarlet at the top, and marked on the face of the limb with yellow and black; the corolla tube in this species is narrow club-shaped, slightly curving towards the top, and the rich yellow of the throat, surrounded by a black band or zone, contrasting with the scarlet of the outer portion of the limb, produces a fine effect. This is a native of Java, as also is *Æ. longiflorus*, which has flowers of a similar shape, but of a deep crimson. The calyx, in these species, consists of narrow segments cut down nearly to the base; but in some other kinds, the calyx forms a deep vase-shaped tube, with a short slightly spreading limb. *Æ. Lobbianus* is one of these, with short elliptic leaves, and a large conspicuous purple calyx, covering half the length of the scarlet flower tubes. Another, *Æ. Javanicus*, has the long tubular calyx green edged with red, and the flowers bright red, marked with yellow rays from the throat; these are both natives of Java. A still different form is met with in *Æ. tricolor*, a slender drooping Bornean plant, with ovate leaves, in which the calyx is cup-shaped with five short rounded lobes, and the flowers have a much shorter tube than in the foregoing. There are many other species, nearly all of ornamental character. [T. M.]

**ÆSCHYNOMENE.** A genus of the *Pea* family (*Leguminosæ*), of which between thirty and forty species are known. They are herbs or small shrubs, with unequally pinnate leaves, and half arrow-headed stipules. The flowers are disposed in axillary or terminal racemes, and are often of a bright yellow colour. The pods are jointed. The species are found in the greatest numbers in Brazil, but they are to be met with in most tropical countries. The pith-like stem of *Æ. aspera* is, on account of its extreme lightness, used in India (where it is called Solah) for making hats, bottle-cases, swimming jackets, and for many other purposes where elasticity and lightness are required. To construct some of these articles, the wood is cut into thin slices and pasted together. It is sold in the bazaars of Calcutta, being brought from the neighbouring marshy places, where it grows to a great size. This substance is purchased by the natives, who use it for floats for fishing nets, and make fancy articles, as model temples, &c., from it. *Æ. monstrosoides* is called the 'Humming-bird bush' at Buenos Ayres, because that bird seems to take more delight in it than in any other flower. *Æ. viscidula*, a native of Florida, has sensitive leaves; and so also, as its name implies, has *Æ.*

sensitive, which is common in the West Indies. [A. A. B.]

**ÆSCULUS.** The Horse Chestnut. The name *Æsculus* (from *æscā*, food) was applied originally to a species of oak which, according to Pliny, was highly prized for its acorns; but how it came to be transferred to the horse chestnut is very uncertain: perhaps, as Loudon suggests, it was given ironically, because its nuts bear a great resemblance, externally, to those of the sweet chestnut, but are unfit for food. *Hippocastanum* (the specific name of the common sort) is a translation of the modern name, which was given, Evelyn tells us, 'from its curling horses broken-winded and other cattle of coughs.' The Horse Chestnut is a tree of large size, frequently reaching a height of fifty or sixty feet, with an erect trunk and a broad pyramidal outline. It may be readily distinguished, even in the depth of winter, by its unusually large buds, set on the extremities of thick and heavy-looking branches, which are evidently destined to bear a weighty tuft of foliage and leaves. These buds are covered thickly with a gummy substance, which protects the tender interior from the cold and wet. As the sun gains power, the gummy covering melts and yields to the expanding pressure from within, and then the scales on which it is overlaid fall off, and the delicate green leaves are rapidly unfolded, encircling a conical mass of embryonic flowers. In this stage the leaves present a singular appearance, drooping with their points towards the ground, as if not strong enough to assume a horizontal position. The buds expand very early in spring, but not prematurely, for within three or four weeks of their first unfolding they have attained their full length, amounting sometimes to eighteen inches. The leaves and flower-buds continue to increase in size until May, when the latter expand; and now the tree, having reached the meridian of its glory, stands forth prominently in all the gorgeousness of leaf and blossom. The downy covering, which was observable on the leaves in their early stage, has disappeared, and they have assumed instead a rich full green. Each leaf is composed of seven broad leaflets, unequal in size, which radiate from a common centre, a character of foliage different from that of any other British tree. The flowers, which grow in long cone-shaped clusters, are snowy white, dashed with pink and yellow, destitute of perfume, but attractive to insects, and, as long as they continue in perfection, very beautiful. They soon, however, become tarnished, and the tree consequently loses much of its grace; yet it is still a fine tree, readily distinguished at a considerable distance by its tiers of large and massive foliage. Out of the numerous flowers contained in every bunch, a few only mature their fruit; the rest drop off soon after they have begun to lose their beauty. The seed-vessels, which are set with short

rigid prickles, attain their full size in October, when they fall off, and, splitting with even valves, disclose three cells, in each of which is contained a roundish polished nut, resembling the sweet chestnut in colour, but not, like it, terminating in a point. It rarely happens that all three nuts are perfected; frequently only two are developed, but the rudiments of all may be discovered. The nuts abound in farinaceous matter, but are too bitter to be fit for human food. They serve, however, as food for goats, sheep, and deer, and are sometimes boiled and given to poultry. Reduced to powder, and mixed with a third part of flour, they are said to make better paste than that composed of flour alone. The timber, owing to its rapid growth, is soft and of loose fibre, and is consequently of little value. The Horse Chestnut is supposed to be a native of Asia, probably of northern India, whence it was introduced into Europe about the middle of the sixteenth century. There is a very fine variety with deep rose-coloured blossoms; and in North America is found another species, the *A. ohioensis* or Buckeye, which is far inferior to the common sort in the beauty of its flowers. The Scarlet Horse Chestnut belongs to a closely allied genus, *PAVIA*, which see. They belong to the order *Supinducæ*. [C. A. J.]

**ÆSTIVAL.** Of or belonging to the summer.

**ÆSTIVATION.** The manner in which the parts of a flower are folded up before the flower expands.

**ÆTHALIUM.** A genus of myxogastrous Funguses, inhabiting more especially stoves and garden-frames where a strong heat is kept up, and doing much damage, by first involving everything in a slimy mass, and then contaminating what it has not overrun, by its myriads of dust-like spores. The principal species, *Æthaliumparvum* (if, indeed, the others are not mere varieties, differing only in colour), appears first under the form of a yellow cream-like mass, which is found to consist, when closely examined, of little wavy viscid strings; this at length swells, and produces abundant dark spores, collected in little heaps separated from each other by thin irregular yellow partitions; the outer surface is rough and scurfy. It sometimes occurs on leaves and rotten wood, in groves and forests, and is found in various parts of the world. The best way of getting rid of it, is dusting the plant, as soon as it appears, with quicklime or salt. This treatment must, however, be followed up perseveringly, as the growth is so rapid that the dusty stage, in which the lime or salt is of little use, may recur before a second application is made. [M. J. B.]

**ÆTHERIA.** A genus of terrestrial Orchids found in the tropics of Central Asia, and nearly allied to *Goodyera*, from which it differs, indeed, in little except the presence of two callosities at the base of the lip. Five or six species are known.

**ÆTHIONEMA.** A genus of *Cruciferae*, containing fifteen or sixteen species, chiefly natives of southern Europe and Central Asia, closely allied to the cress (*Lepidium*), but differing from it, as well as from *Thlaspi* and *Hutchinsia*, by having its four longer stamens winged and with a tooth; also from *Teesdalia*, by having the placentas dilated at the base, and all the seeds attached to their lateral portions; and from *Iberis* by the petals being all equal. Some of the species, when in fruit, present a curious appearance, as the large dorsally-compressed and concave fringed pods are so closely imbricated, that the fruiting raceme resembles the fruit catkin of the hop, the individual pods representing the scale-like bracts. [J. T. S.]

**ÆTHUSA.** Under the name of Fool's Parsley, this plant is well known even to cottage gardeners. It is a common weed in cultivated ground, and is consequently likely to spring up uninvited in the parsley bed. When this happens, it runs a risk of being mistaken for true parsley, since it belongs to the same natural order, *Umbelliferae*; this, however, could never occur if curled parsley only were cultivated. It may also be distinguished by the bluish-green tint of its leaves, and by their fine subdivision. Being an annual, it comes into flower before parsley shows any indication of sending up a flowering stalk. By this unfailing criterion it may be discriminated when growing with the favourite pot-herb which it is supposed to simulate. By equally certain marks it may be distinguished from any other umbelliferous plant which approaches it in habit: each partial umbel, which helps to compose the general umbel of flowers termi-

floral leaves, which hang down vertically. Its flavour and odour are unpleasant, and the seeds are very nauseous. The whole plant is said to be poisonous, and there are instances on record of persons having been made ill by eating it, even in the small quantities in which it is likely to have been present when mixed with parsley. Of its two names, *Æthusa Cynapium*, the former is derived from the Greek *aithe*, to burn, from its acrid properties; the latter, *kynos apion*, 'dog's parsley,' would seem to denote its worthlessness. [C. A. J.]

**ÆXTOXICUM.** See *Agotoxiconum*.

**AFFINITY.** A term in systematic botany, signifying that one thing resembles another in the principal part of its structure, as is the case with Crowfoots and Poppyworts.

**AGALLOCHUM.** The fragrant resinous heart-wood of *Agallaria*; also called *Agila* wood, *Aloes* wood, and *Eagle* wood.

**AGALMYLA.** A small genus of *Generacra* allied to *Echynanthus*, having creeping stems, alternate leaves, and fascicles of axillary flowers. It differs in having the oblique five-lobed limb of the corolla scarcely two-lipped, and in having but two anther-bearing stamens. The species are tropical, inhabiting the islands of the Eastern Archipelago. *A. staminea* is a very handsome plant, epiphytall in habit, creeping and rooting on the trunks of trees, having robust stems, large fleshy gloxinia-like leaves, and axillary fascicles of from twelve to fifteen flowers, which are a couple of inches long, curved tubular, bright scarlet. The stamens are very much exerted. [T. M.]

**AGAMÆ.** A name sometimes given to cryptogams, resting on the supposition that they are asexual plants. [M. J. B.]

**AGANISIA pulchella** is an Orchid with a creeping stem, throwing off at intervals rib-leaved pseudo-bulbs, from the base of which arise spikes of white or cream-coloured flowers. A native of Demerara.

**AGANOSMA.** A genus of *Apocynaceae*, separated from *Echites*, with which it agrees, except that the coronet is cup-shaped or cylindrical, having its five parts so united that they appear only as lobes round the mouth of the cup, while in *Echites* the scales of the coronet are free or but slightly connate. The restricted genus contains eight or nine species, which are shrubs or creepers in the woods of India. Their large panicles of flowers have a showy appearance, and several have a fragrant smell. [W. C.]

**AGAPANTHUS** (literally Love-flower). A small genus of ornamental Liliaceous plants, natives of South Africa, and long cultivated as ornaments of our greenhouses and terrace-gardens. The perianth in this family is tubular, with a short tube and six-parted spreading equal limb; there are six stamens inserted at the base of the limb, with somewhat declinate filaments;

*Æthusa Cynapium.*

inating the stalk, has at its base three approximate narrow pointed bracts or

the ovary is three-celled, with many ovules arranged in two series. The species form fleshy growing perennial herbs, with thick fleshy roots, and linear or somewhat lorate arching radical leaves, from among which springs the scape terminated by a large umbel of bright blue flowers. The species differ chiefly in size, in the breadth of their leaves, and in the intensity of colour in the flowers. The common one is called *A. umbellatus*. [T. M.]

**AGAR-AGAR** (or Agal-agah). The native name of the Ceylon Moss, *Gracilaria hibernica*, a seaweed which is largely used in the East for soups and jellies. Another sign of equal excellence, *Gigartina speciosa*, is abundant on the coasts of the Swan River. The far-famed swallows' nests were formerly supposed to be formed of some seaweed abounding in gelatine; but it is now ascertained that they are formed from a peculiar secretion derived from the birds themselves. [M. J. B.]

**AGARIC BLANC**, (Fr.) *Polyporus officinalis*. — **CHAMPÊTRE**. *Agaricus campestris*.

**AGARICINI**. A group of *Fungi* agreeing with each other in having the hymenium or fructifying surface formed into distinct gill-like plates, the modifications of which, in combination with other circumstances, serve to distinguish the genera. The Mushrooms and Toadstools are familiar examples, in which the gills are highly developed. The Chantarelle, on the contrary, presents a case in which they are reduced to mere veins. Sometimes the gills become hard and corky, as in *Lenzites*, of which a common species, *Lenzites betulina*, grows on old rails. [M. J. B.]

**AGARICUS** (*Agarici*). One of the largest and most important genera of *Fungi*, containing some of the highest forms which these plants are capable of attaining, of which the Common Mushroom is one of the most familiar examples. It is distinguished by the more or less fleshy substance of the hat-shaped receptacle, by being furnished on the under surface, whether supported by a stem or not, with gill-like plates, easily separable in the centre, as if composed of two membranes, the central substance consisting, not of subglobose cells, but of delicate filaments, and being immediately derived from the flesh of the cap or pileus.

The pileus may be either central or lateral, and, in a few instances, where the stem becomes at length obsolete, or is wholly wanting, it is attached to the substance on which it grows by the upper surface, in which case the gills become superior instead of inferior: directed, that is, towards the light, and not, as is usually the case, away from it. Where there is originally a very short stem, the pileus is at first in the usual position, but gradually turns over, so as to bring the gills towards the light. Sometimes the border of the pileus, which was at first resupinate, or having the gills on the upper side, turns

over, so as to bring them into their normal position; in a very few instances alone, the whole plant is permanently resupinate.

The genus *Agaricus* is divided into five natural groups, according as the colour of the spores is white, pink, ferruginous, purple-brown, or black. These divisions, though presenting a few exceptional cases, are on the whole satisfactory, and, after a little experience, easy of determination. These groups are divided into sub-genera, according as they have a common wrapper or volva surrounding the whole plant, or a partial veil attached to the margin or forming a ring upon the stem; and then from various conditions of the stem and gills. Considering the fact that there are at least a thousand good species, it may readily be expected that some difficulties exist in the arrangement, and that the species are not always easily determined. Though, however, as in other parts of the vegetable kingdom, the limits of species are not easily defined, it may be asserted that no more certain species exist in the vegetable world, and that they are not to be considered as mere creatures of chance, without any stability. Many of them are of great beauty and elegance of form and colour, and are attractive from a thousand differences of sculpture, clothing, &c. They occur in all parts of the world, but abound most where the air is moist, with a tolerable degree of warmth. Some species afford the most delicious articles of food, while others are deleterious even when taken in small quantities. It is probable that the number of esculent species is far more numerous than is usually supposed; but as accidents are not unfrequent from confounding species altogether, or mixing poisonous kinds with those which are wholesome, they are far more neglected in this country than they deserve. It is impossible to give any positive rules for distinguishing those which are wholesome; but in general, where the taste of the raw agaric is not decidedly unpleasant, there is little danger, though even this is not without grave exceptions. With proper caution, the real useful kinds may readily be determined without the slightest risk. The common mushroom, however, is said to be poisonous in Italy, and as the bad properties depend upon the ———— which the poisonous alkali is developed — a circumstance which varies with climate, and situation — even those species which are usually wholesome may at times prove deleterious.

Agarics grow in various situations. A vast variety affect dead wood, fallen leaves, and other matters when passing into a state of decay. Some affect the half-dead roots of grass, or large herbaceous plants, as the *Eryngo*. Many grow in pastures, or on the naked ground. Several occur only on dung or in highly-manured land; while a few inhabit principally stoves and ———— structures where the temperature is artificially kept up. Occasionally they appear

under curious circumstances. In Naples, for instance, the grounds of coffee are placed in a heap in some subterranean place of moderate temperature, and an esculent species almost invariably makes its appearance. It is not, however, to be supposed that species which appear under such exceptional cases are creatures of spontaneous growth. They are generally mere altered forms of species which have usually a different habitat.

The word *Agaric*, amongst the old herbalists, had a wider signification than it has now, and was applied to many of the corky funguses. [M. J. B.]

**AGARUM.** A genus of olive-seeded *Algae*, distinguished from *Laminaria* principally by the frond being always perforated with roundish holes. These plants are peculiar to the northern parts of the Atlantic and Pacific Oceans, on the American and Asiatic shores. [M. J. B.]

**AGASTACHE.** A Tasmanian genus of *Proteaceae*, containing only a single species, *A. odorata*, which has yellow apetalous flowers of four sepals and four stamens, one of which is attached by a short filament to the middle of each sepal; the style is filiform, rather shorter than the stamens, and bearing a two-lobed stigma. The flower-spikes are numerous, and, as the name implies, very handsome, from four to five inches in length, and crowded with flowers. The leaves are about two inches long, obtusely lanceolate, occasionally notched at the apex, with a smooth plane surface, subsessile, and rather thick in substance. [H. H.]

**AGASYLLIS.** A genus belonging to the Umbelliferous order, and consisting of a single species, found in the Caucasus. It is a stout perennial herb, about three feet high, furnished with ternately decompound, slightly downy leaves, having lanceolate, decurrent, serrate leaflets. The stems terminate in many-rayed umbels, without general, but with partial involucre of narrow leaflets. The flowers are small and white. The chief characters of the genus are an obsolete calyx margin, compressed oval fruit, with five primary obtuse ribs to each carpel, the two lateral ones shorter than the others, and the number of vittae eight to ten on the back, and five to six on the face of each carpel. [A. A. B.]

**AGATHÆA.** A genus of the Compositæ family (*Compositæ*), comprising twenty species, one of them, *A. abyssinica*, found, as its name implies, in Abyssinia, the others all natives of E. Africa. They are herbs or shrubs, with opposite, toothed or entire leaves, and solitary terminal flower-heads; the ray florets blue and pistilliferous, those of the disk yellow, and having both stamens and pistils. They are nearly allied to the well-known *Michaëlis* Desai (*Aster*), from which they differ chiefly in the pappus of their achenes consisting of one series of bristles. [A. A. B.]

**AGATHIPIA.** A genus of Cape under-

shrubs, with alternate linear-filiform leaves and terminal flower-spikes, belonging to the natural order *Selaginæ*. The genus is characterised by having a five-toothed tubular calyx, an elongated tubular corolla, two included stamens, and a bilocular ovary with a single ovule. By the abortion of one of the cells of the ovary, the fruit is a simple achene, covered by the persistent calyx. [W. C.]

**AGATHOPHYLLUM.** A name intended to express the good qualities of the leaves of the plants to which it is applied. The genus belongs to the Laurel family, among which it may be known by its persistent calyx enclosing the fruit, and by its possessing nine stamens in three rows. The innermost stamens have, on either side of their base, a sessile awl-shaped gland or abortive stamen. The anthers are four-celled. One species, *A. aromaticum*, grows in Madagascar, where the natives use the leaves for a condiment. The fruit is aromatic, but encloses a kernel of an acrid caustic taste, known as Madagascar Clove Nutmeg. [M. T. M.]

**AGATHOSMA.** A genus of Rutaceous plants, so named from their fragrance. They are natives of the Cape, and have regular flowers. The petals are divided, with long claws. They have ten stamens, five of which are fertile, with the anthers tipped by a small gland, and five sterile, dilated above into a petal-like mass, thread-shaped below. The fruit is two to three-celled, each cell containing two ovules placed side by side. *A. pulchella* is said to be made use of by the Hottentots to anoint their bodies, a process very distasteful to European noses. Some of the species are cultivated for their pretty white or purplish flowers. [M. T. M.]

**AGATHOTES.** A genus of plants of the Gentian family, principally distinguished by its corolla, which is divided above into four pieces, while at the base are a number of small glandular pits, each protected by a fringed scale; and by the stamens, which are four in number, slightly connected together at the base. The dried stems of *A. Chirayta*, a native of the north of India, furnish a pure bitter, very similar in its properties to gentian, and used for like purposes under the name of *Chiretta*. By most authors this genus is included in *Ophelia*. [M. T. M.]

**AGATI.** A genus of the Pea family (*Leguminosæ*). *A. grandiflora* is the only species. It is a native of the East Indies and tropical Australia, but is commonly cultivated in tropical countries for the beauty of its flowers. It is a small slender tree twenty or thirty feet high, of rapid growth and short duration; its leaves alternate, abruptly pinnate, with from eight to ten pairs of small leaflets. Flower stalks axillary, bearing from two to four large pea-like red or white flowers. The pods are about eighteen inches long, and as thick as a common quill. In India the flowers, pods, and young leaves are used

by the natives in their curries; a juice is pressed from the flowers and used in curing dimness of vision; and the seeds are eagerly sought after by birds. The bark is powerfully tonic and bitter, and considered effective in small-pox. The wood is useless except for fuel. The tree, being a fast grower and sparingly clad with leaves, is used for the purpose of training the Bétel (*Piper Bétel*). [A. A. B.]

**AGAVE.** A noble genus of *Amaryllidacea*, principally found in Mexico and other parts of South America. The species, of which several are known, are mostly of large size, with massive spiny-toothed fleshy leaves, forming a large spreading tuft, from the centre of which rises the tall flower scape, supporting a large compound inflorescence. The perianth is funnel-shaped, persistent, parted into a limb of six nearly equal divisions; the stamens are six in number, inserted in the tube of the perianth, and becoming exerted after the expansion of the flowers; the ovary is inferior, three-celled, with many ovules in two rows in the central angle of each cell. Some of the species become caulescent, and they are mostly long-lived plants, making comparatively slow progress in growth until the appearance of the flower stem, which, on the other hand, shoots up very rapidly. The best known species, *A. americana*, commonly called the American Aloe, affords a very good illustration of the family. This species is almost stemless; that is to say, its tuft of massive leaves is seated close to the ground, and they spread out on all sides so as to occupy considerable space. These leaves are very thick and fleshy, consisting of hard, firm pulpy matter intermixed with fibres; they are from three to six feet long, furnished with hard spines, both along the margins and at the point. These leaves are very durable, continuing to exist for many years. The plants are long in arriving at a mature or flowering age; indeed, so slow is their progress, under the artificial conditions in which they are placed in our gardens, as to have led to a popular though erroneous notion that they flower once only in a century. In reality they flower but once, the mature condition being attained in a longer or shorter period, ten to fifty or seventy years or more, according to the accelerating or retarding influences under which they are placed. Having, however, acquired full growth, the plant produces its giant flower-stem from the centre of the leaves, after which it perishes. New plants are formed around the base of the old one in the form of suckers. After the first appearance of the stem, it grows very rapidly, until a height of from fifteen to twenty or even forty feet is reached; and, towards the top, many symmetrically-disposed horizontal branches are produced, at the ends of which other branches are crowded bearing the numerous erect yellowish-green flowers, by which a sweetish liquid is secreted. The flowering plant re-

mains for some weeks an object of interest, the flowers being durable and produced in succession.

The American Aloe appears to have been first introduced to Europe in 1561, at which date it is recorded as being in the possession of Cortusius. Parkinson, in 1640, relates that it was first brought into Spain, and from thence spread into all quarters, but is silent as to its being in England. A plant flowered in Paris in 1663. Mr. Verspitt, of Lambeth, flowered one, twelve to fifteen feet high, about 1698, it being then a great rarity. Two were bloomed at Hampton Court about 1714. There is a wood engraving extant with the inscription '*Aloe americana quæ Sonderbusa floruit 1662*.' A plant flowered at Leipzig in 1700. Mr. Cowell, in 1729, flowered one at his garden in Hoxton; and this, he asserts, was the first seen in England, the others, mentioned above, not being the true American Aloe. There is a plate of this plant, by Kirkal, in mezzotinto, dated September 23, 1729. Another flowered at Eaton Hall, in 1737; a plate of it, engraved by Toms from a drawing by Badeslade, bearing date November of that year. This plant opened the crown for flowering on June 5th; the stem-bud appeared on the 15th, and grew five inches a day for some weeks; the flower branches were perfected in twelve weeks, and then it stood for a month while the buds were forming; the number of flowers was about 1,050. Two plants, about fifty years of age, flowered at Hampton Court in 1743, their respective heights being twenty-seven feet and twenty-four feet. The flower stems appeared on June 3rd, were in perfection in the middle of August, and continued blooming till the middle of October. A plant which flowered near Carlsbad in 1754 was twenty-six feet high, and produced twenty-eight branches, which bore above 3,000 flowers. Another flowered at Leyden in 1760, and a third at Friedricksberg, in Denmark, twenty-two feet high, with nineteen branches and more than 4,000 flowers. The tallest of which we have any account, was one that bloomed in the King of Prussia's garden, and this reached forty feet in height.

The species of *Agave* are not only ornamental in character, but are important on account of their uses and products. The plants themselves, with their hard, unyielding spiny leaves, form impenetrable fences, and they are used for this purpose in many parts. The roots as well as the leaves of *A. americana* and some allied species, especially the *Pita* plant, furnish a fibre (*pita* thread) which is extremely tough, and is useful for making twine and rope, and for various other purposes, such as paper-making. Humboldt describes a bridge of upwards of 130 feet span, over the Chinbo in Quito, of which the main ropes, four inches in diameter, were made of *agave* fibre. The fibre is separated by bruising the leaves, steeping them in water, and afterwards beating them.

The juice of the *Agave* leaves yields a

very useful succedaneum for soap. For this purpose the juice is expressed, and then the watery part is evaporated, either by artificial heat or exposure to the sun, until it is reduced to a thick consistence, when it may be made up into balls with the help of lye ashes. This soap lathers with salt water as well as fresh. A gallon of the juice yields about a pound of the soft extract. The roots of *A. saponaria*, a powerful detergent, are employed in Mexico for a similar purpose.

The most important product, however, of the *Agave*, and especially of *A. americana*, is the sap, which continues to flow for some time upon cutting out the inner leaves just before the flower scape is ready to burst forth. The plant is called Metl by the Mexicans, and Maguay de Cocuza in Caracas. Pittes, Acameti, Sequameti, and Maguay-meti, are varieties of this species, which is stated to be common everywhere in Equinoctial America, from the plains even to elevations of 9,000 to 10,000 feet. *A. mexicana*, a closely allied species, is sometimes called Maguel-meti, and also Mangual. According to Humboldt, the plant is extensively cultivated in the interior table-land of Mexico, and, indeed, extends as far as the Aztec language. *A. vivipara* is Theo-meti or Manguel divinum, and in Cumana and Caracas, *A. cubensis* is called Maguay de Cocay.

The sap above referred to is of a sourish taste, and easily ferments, on account of the mucilage and sugar it contains, and in the fermented state is called Pulque by the Spaniards. This vinous beverage, which resembles cider, has an odour of putrid meat, extremely disagreeable, but Europeans who have been able to overcome the aversion which the foetid odour inspires, prefer the pulque to every other liquor. A very intoxicating brandy, called Mexican or Aguardiente de Maguay, is formed from the pulque. Royle states that the Government drew from the agave juice a net revenue of 166,497*l.* in three cities. The fresh leaves of *A. americana*, cut into slices, are occasionally used as fodder for cattle; and the centre of the flowering stem, split lengthways, is said to form no bad substitute for a European razor-strop, on account of the minute particles of silica in its composition. The leaves are also said to be used for scouring pewter. [T. M.]

**AGDESTIS.** A Mexican twining plant originally described by De Candoille, from a drawing of Mocino and Sesse's collection, and which has till lately been very little understood. Specimens recently examined have, however, shown that it forms a very distinct and somewhat anomalous genus of *Phytolaccaceae*.

**AGERATUM.** A genus of Compositae, belonging to the *Eupatorium* tribe of the order, of which the *A. mexicanum*, a well-known occupant of the flower-border, with densely clustered lavender-blue capitules, may be taken as the type. Botanically,

it may be distinguished by its cup-shaped involucre of numerous imbricated linear leaflets, its naked receptacle, and its elongated angular fruit, crowned by a pappus of several awned scales, which are dilated at the base. The genus includes some other annual species in addition to the *A. mexicanum*, but none of them exceed, and few equal it in value for gardening purposes. The *A. conyzoides* very closely resembles it, and has recently appeared in gardens under the name of *Phalacra caelestina*. The *A. angustifolium* and *A. latifolium* have white flowers, but are probably not in cultivation. There is a so-called white variety of *A. mexicanum*, but its flowers are really of a bluish cast. A few perennial species are comprised in the genus; they possess, however, but little general interest. The *Caelestina ageratoides*, a half-hardy perennial, with blue ageratium-like flower heads, much employed in bedding, must not be confounded with the true *Ageratum*. [W. T.]

**AGGLOMERATE.** Heaped up; as the stamens in *Anona* and *Magnolia*, or the male flowers in a pine tree.

**AGGREGATE.** Several things collected together into one body; as the achenes in the fruit of a strawberry; the flowers of *Cuscuta*.

**AGILA WOOD.** The fragrant wood of *Aquilaria evata*, and *A. agallochum*.

**AGLANDEAU.** (Fr.) A kind of Olive.

**AGLAOMORPHA.** A genus of poly-podiaceous Ferns, of the group *Polypodiceae*, distinguished by having the veins of the fronds reticulated, with free included veinlets in the areoles, combined with the following peculiarities:—the free veinlets are divaricated; the fronds are naked, that is, not clothed with scales; they are articulated with the rhizome, and dimorphous, that is, certain sterile dwarfed oak-leaf-like fronds are produced as well as the larger fertile ones; and, finally, the fertile ones have the fertile segments, which are the upper ones, much narrower than the lower sterile ones. There is but one species, *A. Meyeniana*, a native of the Philippine Islands. [T. M.]

**AGNOSTUS.** A synonym of *Stenocarpus*.

**AGNUS CASTUS.** *Filix Agnus-castus*.

**AGRAPHIS.** "The poets feign that the boy Hyacinthus, who was unfortunately killed by Apollo, was changed by that deity into a Hyacinth, which, therefore, was marked with the letters AI, alas! to express Apollo's grief. It is also feigned, that the same flower arose from the blood of Ajax when he slew himself: those letters being half the hero's name."—*Note in Martin's Virgil*. The flower referred to is now supposed to be the Martagon lily, the spots on the petals of which sometimes run together so as to assume the required form; but the name *Hyacinthus*

was given by the earlier botanists to a very different family, of which our common woodland plant, the wild Hyacinth or Blue-bell, was one. This, presenting no tracing of letters on its petals, even to the most imaginative eye, was named by Linnaeus *H. non-scriptus*, or uninscribed Hyacinth. It has now been removed by Link into a distinct genus and named *Agraphis*, a Greek compound bearing the same meaning as *non-scriptus*. The wild Hyacinth, as it continues to be popularly called, is a liliaceous plant common in woods, and too well known to need any description. The Blue-bell of Scotland, the Harebell in poetry, is a totally different plant, *Campanula rotundifolia*. [C. A. J.]

**AGRIMONIA.** A family of herbaceous perennial plants with yellow flowers, belonging to the natural order *Rosaceae*, among which they are distinguished by bearing their enclosed seeds in the hardened calyx, which is furnished on the outside with a circle of hooked bristles. The British representative of the genus, *A. Eupatoria*, is a common way-side plant, with interruptedly pinnate leaves, a scarcely branched stem about a foot and a half high, and an elongated spike of starry yellow flowers. When in fruit the calyx becomes inverted. The foliage is astringent and aromatic, and is an ingredient in several 'herb teas.' Its medicinal virtues, though far inferior to what they were anciently supposed to be, have retained for it a place in the repertory of herb collectors, who recommend it as tonic and astringent. It contains tannin, and will dye wool of a murren colour. A Canadian species is said to be used with success as a febrifuge. [C. A. J.]

**AGRIMONY.** *Agrimonia*. —, **HEMP.** *Eupatorium cannabinum*. —, **WATER HEMP.** An old English name for *Bidens cernua* and *B. tripartita*.

**AGRIOPHYLLUM.** A small genus of *Salsolaceae*, containing two species, natives of Caucasian Siberia. They are annual plants, with alternate, sessile, entire leaves, and sessile axillary flowers in short squarrose spikes. The calyx, when present, consists of a single membranaceous sepal. There are three to five stamens, and two filiform styles. The fruit is a vesicular compressed capsule. [W. C.]

**AGRIPAUME.** (Fr.) *Leonurus Cardiac.*

**AGROSTEMMA.** A genus of *Caryophyllaceae*, of the tribe *Sileneae*, founded by Linnaeus, but now generally regarded as a section of the genus *Lychnis*, from which it only differs in the elongated segments of the calyx limb, in the petals being without a prominent scale at the base of the expanded portion, and in the capsule opening by valves alternate with and not opposite to the calyx segments. *Lychnis (Agrostemma) Githago*, the well-known weed Corn Cockle,

with large, entire, purple petals, is the only species belonging to the section as it is now limited; the rest of the Linnean species being referred to the section *Coronaria*. [J. T. S.]

**AGROSTIS.** A genus of Grasses, typical of the tribe *Agrostideae*, and known by the English name of Bent grasses. The principal characters, which serve to distinguish this genus from its allies, are the flowers being single within the calyx glumes, and having short hairs at their base, and the upper glume being smaller than the lower. The species are numerous, no fewer than 171 being described in *Steudel's Synopsis Plantarum Graminearum*, and their range over the surface of the globe is also very extensive. The Falkland Islands, Nootka Sound, and Tasmania may be quoted as some of the outlying stations for this species of *Agrostis*. In the British Isles, the Bent grasses are of general occurrence on all damp pastures, as well as on dry waste ground. The Marsh Bent, *Agrostis alba*, is the once famous Florin grass of the late Dr. Richardson, who, by his writings on the subject, brought it prominently before the agricultural public, and caused it to be cultivated on a rather extensive scale, particularly in Ireland. It has not, however, been found to realise the expectations held concerning its worth, and, consequently, is not extensively grown at the present time. It is remarkable for having the long stems lying prostrate on the surface of the ground, and throwing out roots at their nodes or joints, by which means they frequently extend four feet or more from the main root of the plant without flowering. The Dog Bent, *Agrostis canina*, is the grass which sick dogs, and even cats, sometimes chew, for the purpose, it is supposed, of causing them to vomit. This species wants the inner glume or pale to the flower. *Agrostis pulchella*, a native of Quidia, is cultivated in gardens, for the beauty of its elegant panicles of flowers, which, on being cut before they are fully ripe, remain a long time in a dry state, without much alteration in their appearance. Some of the foreign species of this genus are valuable as pasture grasses in the parts of the world where they grow spontaneously. [D. M.]

**AGROSTOPHYLLUM.** A genus of *Jaya* Orchids with fleshy stems, narrow leaves, and small flowers packed closely in terminal heads. Two or three united species are known to botanists.

**AGUILBOQUIL.** A Chilean name for the berries of *Lardizabala interjecta*.

**AIAULT.** (Fr.) *Narcissus Pseudo-Narcissus*.

**AIGLANTINE.** (Fr.) *Aquilegia vulgaris*.

**AIGLE-IMPÉRIAL.** (Fr.) *Pteris aquilina*.

**AIGRELIER.** (Fr.) *Pyrus torminalis*.

**AIGREMOINE.** (Fr.) *Agrimonia*; also *Aremonia agrimonoides*.

**AIGUILLE DE BERGER.** (Fr.) *Scandix Pecten-Veneris*.

**AIL.** (Fr.) *Allium sativum*. — À TOUPET. *Muscari comosum*. — DES BOIS. *Allium ursinum*. — D'ESPAGNE. *Allium Scorodoprasum*. — DORE'. *Allium Moly*. — D'ORIENT. *Allium Ampeloprasum*.

**AILANTUS.** The *Vernis du Japon* of the French, *A. glandulosa* of botanists, is in its native countries, China and India, where it is called Ailanto, a tree of large size and handsome appearance, bearing numerous pinnate leaves from one to two feet long or more, and clusters of greenish flowers of a disagreeable odour. It is of rapid growth, making, when favourably situated, annual shoots from three to six feet in length. Its German name, Götterbaum, 'Tree of the gods,' is said to be a translation of *Ailanto*. French arboriculturists recommend that its lateral branches should be annually lopped off, when the main trunk will ascend perpendicularly and sustain a symmetrical spreading canopy. In France and Italy, it is

*Ailanthus glandulosa*.

much valued as a tree for shading public walks, and is planted for that purpose along with the tulip-tree, horse-chestnut, plane, &c. Its leaves are not liable to be attacked by insects, which is a great recommendation; nevertheless they are the favourite food of the silk moth, *Bombyx Cynthia*; and they continue on the tree and retain their green colour till the first frosts of November, when the leaflets suddenly drop off, the leaf-stalks remaining on often a week or two longer. The wood is yellowish-white, satiny, and well suited for the purposes of the cabinet-maker. There

specimens, both in England and of the Continent, exceeding sixty feet in height. The name 'Japan varnish,' seems to have been applied to it through some mistake. The genus belongs to the *Simarubaceae*. Other species are stove-plants. [C. A. J.]

**AINSWORTHIA.** A genus of *Umbelliferae*, containing three species, natives of Palestine, having the habit of and usually referred to *Tordylium*, from which, however, it differs in the absence of the calyx teeth, and in having the margin of the fruit smooth. This genus was separated from *Hasselquistia* by Boissier, because of the breadth of the oleiferous vittæ in the fruit, and also from the characters of the calyx and fruit, which are the same in *Hasselquistia* as in *Tordylium*. [W. C.]

**AIR PLANTS.** A common name for *Aerides*. The name is also applied to Epiphytes, or plants which grow on trees and other elevated objects, not in the earth, and derive their nutriment from atmospheric moisture. They are to be distinguished from terrestrial plants, or those growing in earth, and from parasites, which derive nourishment directly from other plants on which they grow. [T. M.]

**AIRA.** A genus of *Crassæe*, belonging to the tribe *Avneræ*, distinguished by having two perfect florets and frequently the rudiment of a third floret within the glumes. The pales are notched at the point, and bear short awns on the back, the awns being in most instances kneed or bent. The species are numerous, and have an extensive range of localities over the surface of the earth. Those that are natives of the British Isles are not held in great estimation for agricultural purposes, being of a coarse wiry, nature.

The tufted Hair-grass, *Aira cæspitosa*, is one of the tallest-growing British grasses: indeed, under favourable circumstances, the culms, or stems frequently attain a height of six feet. In boggy land, the close growing tufts form what are called tussocks, which are found extremely useful for stepping on when walking over soft watery places. [D. M.]

**AIRELLE.** (Fr.) *Vaccinium*. — RAISIN D'OURS. *Vaccinium Arctostaphylos*. — ROUGE. *Vaccinium Vitis idæa*.

**AIROCHLOA.** A name given to certain festucaeous Grasses, now generally referred to *Koeleria*. [T. M.]

**AIROPSIS.** A genus of Grasses belonging to the tribe *Avneræ*, distinguished from the genus *Aira* by the pales being partly attached, or adnate to the corn or seed. The majority of authors do not, however, consider this character, along with some others of minor importance, sufficient to separate it permanently from *Aira*, and, consequently, retain the species which Fries included under it, as a section of the genus *Aira*. The two British species, namely, *Airopsis coryophylla* and

*A. proceros*, are small elegant grasses, which flower in spring and the early part of summer, neither of them of much value as agricultural grasses, being only of annual duration, and loving to grow on dry barren sandy spots which produce little else besides them. [D. M.]

**AITONIA.** This name is applied to certain plants (usually referred, but with some doubt, to the family of *Rapindavea*), in honour of Mr. Aiton, the former superintendent of Kew Gardens. The calyx is deeply divided into four divisions; the petals are four; the stamens eight, projecting from the corolla, their filaments united into a tube arising from beneath the ovary, which latter is surmounted by a thread-shaped style, terminated by an obtuse stigma. The fruit is membranous and triangular, of one cell, with several seeds attached to a central receptacle. *A. cypensis* is a small shrub sometimes cultivated in this country. [M. T. M.]

**AIZOON.** A genus of plants referred by Endlicher to *Portulacaceae*, but separated from that order by Lindley on account of their want of petals and the small number of stamens, and formed, with some allied genera, into a distinct order, *Tetragoniaceae*. The calyx is five-partite, and coloured on the inner surface. The stamens, about twenty in number, are inserted singly or in from three to five bundles in the base of the calyx. There are five subclavate stigmas; the ovary has five cells, each containing from two to ten ovules. The genus contains more than twenty species of prostrate herbaceous plants, very abundant in Southern Africa, and found sparingly also in Southern Europe, Northern Africa, and Arabia. The ashes of *A. canariensis* and *A. hispanicum* abound in soda. [W. C.]

**AJAX.** A subdivision of the genus *Narcissus*, including the common Daffodil, and other species having a long trumpet-shaped coronet to the flowers. [T. M.]

**AJONC, or AJONG MARIN.** (Fr.) *Ulex europaeus*.

**AJOWAINS.** The carminative fruits of some Indian species of *Ptychotis*. Also called *Ajwain*.

**AJUGA.** A genus of plants belonging to the Labiate faml', presenting nothing remarkable in appearance, nor possessing any properties which render it valuable. The species are all herbaceous, and the majority are annuals. The flowers either grow in whorls of six or more, or singly in the axils of the opposite leaves: sometimes contracted so as to resemble a spike, in other species more loosely, but in all cases accompanied by leaves or leaf-like bracts. Several species are furnished with stolons or runners. Of the three British species, the commonest is *A. reptans* (common Bugle), a woodland and hedge-side plant, rendered noticeable by the dull purple tinge of its upper leaves

and bracts. A section of the family, named Ground Pine, is represented in Britain by *A. Chamæpitys*, a tufted spreading herb with three-cleft, very narrow hairy leaves, and yellow flowers dotted with red. Bugle was formerly held in high esteem for its vulnerary properties. 'Ruellius writeth that they commonly said in France, howe he needeth neither phisician nor surgeon that hath Bugle and Sanicle, for it doth not onely cure woundes, being inwardly taken, but also applied to them outwardly.'—Gerarde. Other medical virtues assigned to the Bugle have as little foundation, in fact, as the above. [C. A. J.]

**AKEBIA.** A small genus of *Lardizabalaceae*, distinguished by having separate male and female flowers; the former consisting of a three-leaved calyx of ovate-lanceolate, concave, nearly equal segments, six subequal free stamens in two rows, and the rudiments of six ovaries; the latter formed of three large roundish concave sepals, six to nine dwarfed abortive stamens, and from three to nine distinct oblong-cylindrical ovaries, crowned by a short peltate stigma. The species are climbing plants of Japan and China, commonly cultivated in gardens, and also forming welcome half-hardy climbers in those of our own country. One of them, *A. quinata*, has its freely running stems furnished with very pretty leaves, consisting of three to five ovate or obovate entire obtuse emarginate leaflets; and from the axils of these leaves grow the racemes of dull red-purple fragrant flowers, of which the upper are smaller and sterile, the lower larger and fertile. Mr. Fortune found this plant in Chusan, growing on the lower sides of the hills in hedges; when climbing on other trees, its branches hung down in graceful festoons, attracting attention by the delightful fragrance of their flowers, the colour of which, a dark purplish brown, is not particularly showy. [T. M.]

**AKA.** The New Zealand *Metrosideros scandens*.

**AKEE TREE.** *Begonia* (or *Cupania*) *sapida*.

**AKHROUT, INDIAN.** *Aleurites triloba*.

**AKRA.** The name, in India, of the fodder Vetch, *Vicia sativa*.

**AKUND.** The *Calotropis gigantea* of India.

**ALA.** One of the lateral petals of a papilionaceous flower. Also a membranous expansion of any kind; as that round the seed of a bignoniad, from the summit or side of a seed-vessel, or on the angles of a stem. Formerly, the axil, but not now employed in that sense. The word is generally used in the plural form, *alae*.

**ALABASTRUS.** A flower-bud.

**ALAMANIA panicea.** A little creeping Mexican Orchid, scarcely distinct from *Epidendrum*. It has crimson flowers, with a small bar across the lip.

**ALANGIACEÆ** (*Alangiads*). A natural order of plants inhabiting tropical Asia. With the exception of the genus *Nyssa*, which is found in the United States, all are trees or shrubs with inconspicuous flowers, structurally similar to those of certain myrtles. Their fruit is succulent and eatable, but not agreeable to European tastes. The principal genera are *Alangium* and *Nyssa*. Eight or nine species are all that are known.

**ALANGIUM**. A genus of Indian trees, containing two, or perhaps three species, and belonging to the natural order *Alangiaceæ*. The leaves are alternate, exstipulate, entire, and reticulated on the under surface with transverse veins. The calyx is campanulate, five to ten-toothed; the petals, equal in number to the segments of the calyx, are linear and reflexed. The stamens are twice or four times as many as the petals, and have filaments which are very hairy towards the base, and bear adnate anthers. The ovary is coherent with the tube of the calyx, and somewhat crowned with its limb; it is one-celled, with one pendulous ovule. The single subulate style is expanded at the base into a coloured thick fleshy disk, covering the top of the ovary. The fruit, a fleshy one-seeded drupe, is edible but not palatable, being mucilaginous and insipid. The roots are aromatic, and the timber good and beautiful. Some of the branches occasionally become spinescent. The Malays believe the species of *Alangium* to have a purgative hydragogic property. De Candolle established the natural order *Alangiacæ* on this genus, separating it from *Myrtaceæ* and other allied orders, because of its more numerous petals, adnate anthers, and one-celled fruit; and from *Combretaceæ*, on account of its adnate anthers, albuminous seeds, and flat cotyledons. [W. C.]

**ALARIA**. A genus of dark-spored *Algae*, consisting of a very few species, confined to the colder regions of the North Atlantic and Pacific. The frond is from three to twenty feet long, of a membranous substance, but is furnished with a strong central nerve or rib, and is frequently much torn and split by the action of the waves; it is supported below by a short cylindrical stem, from the sides of which finger-shaped processes are given off, in whose outer coat the spore cases are immersed, supported on short peduncles, the contents of which are ultimately divided into four spores. We have a single species only upon our own coasts, *Alaria esculenta*, which is, however, well known by the Scotch under the name of Badderlocks, Henware, Honeyware, and Murlins, and is the best of all the esculent *Algae* when eaten raw, the midrib and fruit-bearing appendages being the parts most in use. The name of Badderlocks, which has puzzled etymologists, is clearly a corruption of Balderlocks, or the locks of Balder, a Scandinavian deity to whom other plants have been dedicated. [M. J. B.]

**ALASANDI** or **ARHAR**. An Indian name for a common Eastern pulse, *Dolichos Catjang*.

**ALATE**. Furnished with a thin wing or expansion.

**ALATERNUS**. The common garden name of *Ehamnus Alaternus*, a well-known evergreen shrub.

**ALBEFACTIO**. A condition of plants induced by absence of light, commonly called Blanching, in which little or no chlorophyll is formed, the peculiar secretions are diminished, and the tissues are tender and unnaturally drawn out; and thus plants, which in a state of health are tough, unwholesome, and unfit for food, become palatable and wholesome. If light be restored, the plant may gradually recover its tone, but if it is absent for any great length of time death is sure to ensue. Some succulent plants, and those which have tubers, will sometimes survive the first season, but in general the confinement of a few months at the time of active growth is fatal. Flowers, when bleached, as of the phyllanthoid *Cacti*, sometimes recover their colour when exposed to light, but liliac which are blanched for ornamental purposes remain white, though their leaves acquire a yellowish-green tinge. [M. J. B.]

**ALBERTINIA**. A genus of the Composite family, containing about a dozen species. They are shrubs or small trees, with alternate, stalked, entire leaves attenuated at both ends, and either covered with short white hairs, or entirely smooth. Their flower-heads are arranged in compact globular bunches at the ends of the branches, each head containing from one to three florets. The hairs of the pappus are filiform, arranged in two or many series, and often rose-coloured. All of them are natives of Brazil. Their uses, if any, are not known. [A. A. B.]

**ALBIZZIA**. A genus of the Leguminous family, related to *Acacia*. The name *Besenna* was given by M. Richard to an Abyssinian tree, of which the flowers and fruits were unknown to him. Since then the plant has been found in flower, and proves to be a species of *Albizzia*. This plant, the *Albizzia anthelmintica*, is a small tree, with bipinnate leaves made up of one or two pinnae, each of which bears three or four pairs of obovate, unequal-sided leaflets, about an inch long and half an inch broad. The flowers are in axillary stalked heads. The Abyssinian name of the plant is *Besenna* or *Mesenna*, and its bark is much used in that country in the treatment of tapeworm (*Tania solium*), a pest to which the Abyssinians are much subject for their eating raw meat. [A. A. B.]

**ALBUCA**. A genus of African *Liliaceæ*, chiefly from the Cape of Good Hope, closely resembling *Ornithogalum*, but having the three inner segments of the perianth closed over the stamens, while the three outer ones are spreading; three of the

six stamens are often sterile. They are bulbous plants, easily cultivated in the greenhouse when grown in pots with sandy peat earth; but they are not very ornamental, having green or yellowish flowers striped with white, and leaves more or less like those of the hyacinth. Seventeen or eighteen species have been in cultivation in this country. [J. T. S.]

**ALBUMEN.** The matter that is interposed between the skin of a seed and the embryo, or the vitellus, if there is one. It is, in reality, whatever substance is deposited in the cells of the nucleus during the growth of the seed.

**ALBUMINOUS.** Furnished with albumen when perfectly ripe. A term exclusively applied to seeds.

**ALBURNITAS.** A tendency to remain like albumen. A disease of trees, when white rings of wood are interposed among heart-wood.

**ALBURNUM.** The sap wood of a tree; the younger wood, not choked up by sedimentary deposit, and therefore permeable to fluids.

**ALCAMPHORA.** A remedial preparation from *Croton perdicipes*.

**ALCÉE DE LA FLORIDE.** (Fr.) *Gordonia Lasianthus*.

**ALCHEMILLA.** A genus of herbaceous annual or perennial plants, belonging to the natural order *Rosaceæ*. All the species have lobed leaves, and inconspicuous yellow or greenish flowers. *A. vulgaris*, the common Lady's Mantle, is frequent in wet pastures and the borders of woods: the leaves are rather large, roundish, seven to nine lobed, plaited, and notched at the edges; the flowers, though small, are numerous, of a golden green colour, and collected into forked clusters. It often occurs in gardens, where it is valued more for the pleasant green of its foliage than for any shapeliness while in flower. Its properties are astringent, and slightly tonic; hence it comes within the province of the 'stimpler.' *A. alpina* is a mountain species, found on the banks of rivulets in Scotland and the North of England. The leaves of this species are deeply divided into five oblong leaflets, and are thickly covered with lustrous silky hair. A form of this plant in which the leaflets are connate for one-third of their length is known as *A. corymbosa*. *A. crevenole* (Parsley-Piert) is a small annual plant, a few inches long, with jagged leaves, and tufts of minute green flowers growing in their axils. It grows abundantly in cultivated fields, and on hedge banks. *A. alpina*, and some of the foreign species, are well adapted for rock-work. [C. A. J.]

**ALCORNOCO, or ALCORNOQUE BARK.** The bark of several species of *Syrcea*. The Alcornoque of Spain is the bark of the cork-tree.

**ALDER.** The common name for *Alnus*. — **BERRY-BEARING.** *Rhamnus Frangula*. —, **BLACK.** An old English name for *Rhamnus Frangula*; also applied in America to *Prinos verticillatus*. —, **RED.** A name given at the Cape of Good Hope to *Cunonia capensis*. —, **WHITE.** A name given to *Platylophus trifolius* in South Africa; also to *Clethra alnifolia* in North America.

**ALDROVANDA.** A genus of *Droseraceæ*, containing a single species found in Southern Europe, growing in still water. This plant, *A. vesiculosa*, is remarkable for its curious leaves, which are in whorls of six to nine; they are pellucid, and inflated at the extremity, so as to form a vesicle, which acts as a float; the leaf-stalk is flat (not inflated), with four or five bristles at the extremity; the stems are only a few inches long, generally simple, with the whorls of leaves approximate; the flowers are white, and rather small and solitary, borne on longish slender peduncles, springing from the axils of the leaves. [J. T. S.]

**ALE-COST.** An old English name for *Pyrethrum Tanacetum*, commonly known as *Balsamita vulgaris*, the Costmary of gardens.

**ALE-HOOF.** An old English name for *Nepeta Glechoma*, the Ground Ivy.

**ALEPYRUM.** A genus of *Desmodiaceæ*, containing three species of small tufted herbaceous plants, natives of the shores of New Holland. They have solitary or few terminal flowers, with two bracts; a single stamen; and six or eight ovaries, with simple styles to each. The genus differs from *Centrolepis* in wanting bracteoles, and in the spathe consisting of one or very few flowers. [W. C.]

**ALETRIS.** A genus of North American herbaceous *Hamodoraceæ*, distinguished by the following features:—The perianth is half-inferior, tubular, with a six-cleft spreading or funnel-shaped limb; the six stamens are inserted into the base of the perianth segments, and have flat filaments and somewhat arrow-shaped anthers; the ovary is three-lobed, pyramidal, with a style composed of three connate bristles, distinct at the base, but joined at the top into a simple stigma; the capsule is pyramidal, three-celled, trilocous, enclosed in the perianth, and opening at the point in three directions; and the seeds are numerous, minute, striated. *A. farinosa*, called Colic root and Star grass, is a dwarf perennial with somewhat distichous radical leaves, which are lance-shaped, ribbed, and sessile or somewhat sheathing at the base. The stem is simple, invested with remote scales, one to three feet high, terminating in a spiked raceme of short-stalked, white, oblong, bell-shaped flowers, the outer surface of which has a roughish frosted or mealy appearance. It is one of the most intense bitters known, and is used both as a tonic and a stomachic. [T. M.]

**ALEURITES.** A genus of the Spurge-  
wort family (*Euphorbiaceæ*). The only  
species, *A. triloba*, called the Candleberry  
tree, forms a tree of considerable mag-  
nitude, attaining the height of thirty to forty  
feet, and, though originally a native of  
the Moluccas and the S. Pacific Isles, is  
commonly cultivated in tropical countries  
for the sake of its nuts. The leaves are al-  
ternate, four to eight inches long, stalked,  
and without stipules, either oval acute and  
entire, or from three to five lobed, and,  
like all the young parts, covered with a  
whitish starry pubescence. The flowers  
are small and white, growing in clusters  
at the apex of the branches, the males and  
females together in the same cluster, the  
former being the most numerous. The  
fruit is two-celled, fleshy, roundish, and  
when ripe of an olive colour, its greatest  
diameter about two and a half inches; each  
cell contains one seed, in form something  
like a small walnut, the outer shell of which  
is very hard. The kernels, when dried and  
stuck on a reed, are used by the Polynesian  
islanders as a substitute for candles;  
and as an article of food in New Georgia.  
They are said to taste like walnuts. When  
pressed they yield a large proportion of  
pure palatable oil, used as a drying oil for  
paint, and known as Country Walnut Oil  
and Artists' Oil. In Ceylon it is called Ke-  
kune Oil, and in the Sandwich Islands,  
where it is used as an mordant for their  
vegetable dyes, 'Kukul Oil. In these is-  
lands alone about 10,000 gallons are an-  
nually produced. It has been imported to this  
country, but not to any considerable extent,  
and fetches about 20¢ per imperial ton. The  
cake, after the oil has been expressed, is  
esteemed as a food for cattle, and also as  
manure. 'The root of the tree affords a  
brown dye, which is used by the Sandwich  
Islanders for their native cloths.' The  
plant is known in India under the name of  
Indian Akhrout. [A. A. B.]

**ALEXANDERS.** A common name for  
*Smyrnum Olusatrum*. Sometimes written  
Alisanders. — **GOLDEN.** An American  
name for *Zizia*.

**ALFA.** The fibre of *Macrochloa tenacis-  
sima*, used in Algeria for paper-making

**ALFALFA.** The Spanish name of Lu-  
cerne, *Medicago sativa*.

**ALFREDIA.** A genus of the Composite  
family, founded on the *Chicus cernuus* of  
old authors, which was cultivated in this  
country so long ago as 1760 by Miller in  
the Chelsea garden, and was figured by  
him in a publication illustrating his re-  
nowned *Gardener's Dictionary*. *A. cernua*,  
a native of Siberia, is a rank-grow-  
ing, thistle-like plant, one to seven feet  
high, with stalked heart-shaped root-leaves  
nearly a foot long, having their serrate  
blades white underneath, and their foot-  
stalks crisped and prickly; the stem  
leaves are sessile and heart-shaped, except  
the uppermost, which are narrow lance-  
shaped. Each branch ends in a nodding

yellow thistle-head, rather more than an  
inch across, containing numerous tubular  
florets, enclosed by an involucre of spiny-  
pointed and lacerated scales. From *Ser-  
yatula* the genus differs in the pappus  
hairs (which crown the obovate streaked  
achenes) being bearded instead of rough,  
as well as in the long feathery tails of the  
anthers. Four species are known, all  
Siberian. [A. A. B.]

**ALGÆ.** A large and important tribe of  
*Cryptogams*, far the greater part of which  
live either in salt or fresh water, a few only  
deriving their nourishment from the mois-  
ture contained in the surrounding air.  
Though many of them are confined to par-  
ticular kinds of rocks, and have something  
resembling a root, it is not probable that  
they draw any important part of their  
nourishment from the substance on which  
they grow.

The higher *Algæ* have a distinct stem,  
from which arise variously-shaped expan-  
sions, which often assume the semblance  
of leaves; but, though these are often  
strictly symmetrical, they never follow the  
spiral arrangement which is so marked in  
phenogams, and which exists even among  
mosses. In many the stem is quite ob-  
literated, and the whole plant consists of  
an expanded membrane, consisting of one  
or more strata of cells, as the case may be.  
Frequently there is no expansion, and the  
whole plant, whether solid or fistulose,  
simple or branched, is everywhere more or  
less cylindrical. In other cases, again, it  
consists of a mere string of articulations;  
while in others, the whole is reduced to an  
adnate crust or a shapeless jelly, or to  
single cells. In one curious division, the  
frond, though often much divided, con-  
sists of a single cell only, however com-  
plicated, filled with endochrome. Whatever  
the colour of *Algæ* may be, it appears that  
they act upon the atmosphere in the same  
way as phenogams, that is to say, that  
they absorb carbonic acid and give out  
oxygen under the influence of light.

*Algæ*, whatever may be their outer form,  
or whatever their degree of complication,  
are cellular plants, in a very few instances  
only presenting anything like vessels,  
though the cell-walls themselves have fre-  
quently a spiral structure. The spores are  
often nothing more than the endochromes  
of cells, whether terminal, or chained to-  
gether like the beads of a necklace, more  
consolidated than usual, and occasionally  
broken up into four or more distinct re-  
productive bodies. There are often two  
sorts of fruit upon the same or on different  
fronds, the one of which is regularly tetra-  
sporous, the other variable in character,  
presenting often the appearance of a cap-  
sule perforated at the apex. Amongst the  
lower *Algæ* the spores are often furnished  
with one or more flagelliform processes, or  
with vibrating cilia, by means of which  
they move from place to place for a greater  
or less time, as if endowed with spontane-  
ous motion, till they become attached and  
germinate. In most of the subdivisions

sexual differences have been observed; the antheridia, or male organs, containing bodies often closely resembling the spermatozoa of animals. In some of the species fructification does not take place till the threads throw out little processes, by means of which a complete union with one another is established, the endochrome of the joint of one thread passing through their lateral tube and uniting with that of an opposite joint, and then forming a perfect spore.

In many of the lower *Algæ*, as indeed in some of the higher, reproduction takes place for an indefinite time by repeated subdivision of the original individual. At times, however, the proper fruit makes its appearance, and sometimes in such an anomalous form as to cause much perplexity.

*Algæ* are related on the one hand to Funguses, and on the other to Lichens. Distinctive characters are more easily derived from their respective habits than from differences of structure.

The term *Algæ* had formerly a far wider range than at present, and it is now almost entirely confined to aquatic cryptogams. There is no English word which will comprise the whole. The most convenient, perhaps, is that of *Hydrophytes*, which, however, does not apply to the aerial species, and is objectionable because there are many plants with a submerged habit which are not *Algæ*.

*Algæ* are divided into three great classes, each of which comprises a number of very distinct groups, the more prominent of which will be noticed in their proper order. These three classes are characterized by the colour of their seeds, which correspond for the greater part with the general tint of the plants.

1. MELANOSPERMÆ, or olive-spored
2. RHODOSPERMÆ, or rose-spored.
3. CHLOROSPERMÆ, or green-spored.

The first of these comprises the olive-coloured species, which from their size and abundance are so conspicuous on our shores, or which float in dense masses, sometimes many leagues in extent, on the surface of the ocean. On our own coasts they attain the length occasionally of twenty feet or more, and in the genus *Laminaria* individuals are sometimes large enough to be a load for a man; but this is nothing to the size attained in the southern seas, or even in some parts of the northern hemisphere. Individuals of the genus *Macrocystis* attain a length of a hundred feet or more, and *Lessonia* forms submarine forests, the stems resembling the trunks of trees. Some of the lower species have nothing like leaves, and are reduced to mere articulated threads, or a shapeless mass.

The second class comprises those charming seaweeds, remarkable for their elegance of form, delicacy of texture, and brilliancy of colour, which attract the at-

tention of all wanderers along the coast. These are often very abundant, but they seldom attain any considerable size, and some of them are as delicate as moulds.

The third class contains most of the smaller species, in which the frond seldom assumes the form of a membrane, but is more frequently reduced to a mere thread, or even to single articulations. A few only are conspicuous objects, amongst which the genus *Caulerpa* is most remarkable, affording on warm sandy coasts an abundant supply of nutritive food for turtles. Of the smaller and more obscure species, in which there is often no point of attachment, we have the most exquisite microscopical objects, exhibiting an almost inexhaustible variety of form and sculpture.

In the two latter classes, more especially, many species are so masked by calcareous matter as to present the appearance of corals, with which productions they have accordingly been arranged. A weak solution of hydrochloric acid, however, soon changes the fixed carbonate of lime into soluble chloride of calcium, and the structure and fruit are then unmasked and found to correspond with those of true *Algæ*. In *Diatomaceæ* silex instead of lime is imbedded in the substance of the cells.

Amongst the productions which appear upon rocks exposed to the action of the atmosphere, the lower *Algæ* are often the first to make their appearance. Even the cold surface of snow and ice produce the bright red *Algæ*, known under the name of Red Snow, while allied species appear on darker grounds. These gradually, by their decomposition, afford soil for higher growths.

The larger species of *Algæ* afford a useful though coarse article of food to men and domestic animals, not to mention the numberless tribes which they support in their own element. The Laver of our south-western coasts is, however, considered by many an object of luxury, though, like olives, it is not in general relished at first. With use, however, it is esteemed by many a most acceptable condiment. Many of the rose-coloured *Algæ* abound in gelatine, and in consequence they are collected to make a fine kind of glue, or as a substitute for isinglass. Carrageen or Irish Moss, which consists, in great measure, of common species of *Chondrus*, is a most useful article in cattle feeding, when boiled and mixed with other nutritious matters. Amongst the *Chlorosperms*, besides the Laver above mentioned, a species of *Noctac* is much used as an ingredient in soup by the Chinese; but it seems not to have much to recommend it beyond the quantity of bassorin which it contains. *Durrillaea nitida* is employed for the same purpose in Chili. The siliceous coats of *Diatomaceæ*, of which the substance called Tripoli is entirely composed, form a capital substance for polishing, and the close parallel lines of extreme fineness, with which they are frequently grooved, make them very useful in microscopical researches as a test.

The larger *Algae* were formerly much employed in the manufacture of kelp. More advanced chemical knowledge has, however, entirely suspended the practice, carbonate of soda being now obtained from other sources, to the great detriment of many of the proprietors on the sea-coasts of Scotland. They form also a very valuable manure, and it has lately been proposed by the writer of this notice to manufacture a portable manure from *Algae* partially dried and then ground down with conical crushers, the pulpy mass being mixed with peat ashes and dried in strongly ventilated sheds.

Some of the lower *Algae* approach, as before observed, very near to moulds, and in consequence many of these, when submerged and barren, have been assigned to *Algae*. Such productions, however, as yeast, and other matters which occur in fermenting bodies, are now pretty well understood, and are referred to a more befitting place in the vegetable kingdom. It is very doubtful whether any true alga is parasitic on animals, those which have been supposed to be so, as *Sarcina*, &c., being in all probability *Fungi*. The curious productions which grow on fish and other aquatic animals, as *Leptomitris*, &c., are the only exception, if, indeed, these also should not be excluded. *Algae* extend to the utmost limits of vegetation, and some of them are found at great depths in the sea. The limits of the distribution of species are not so extensive as in *Fungi*, though some have a very wide range. Many fossil species are described, but the nature of the greater part is obscure. [M. J. E.]

**ALGAROBIA.** The fruit of *Ceratonia siliqua*, —SOUTH AMERICAN. *Prosopis diaca*, and others. —DU CHILL. *Prosopis siliquastrum*.

**ALGAROVILLA.** The seeds and husks of *Prosopis pallida*, a tannin material obtained from Chili.

**ALHAGI.** An Arabic name applied to a genus of *Leguminosae*, characterised by having papilionaceous flowers in clusters, the pod stalked, woody, contracted between the seeds, but not dividing into separate joints. The plants are shrubby, with simple leaves and spiny flower stalks, and inhabit Southern Asia and Western Africa. A manna-like substance is produced from some of these plants in Persia and Bokhara, and is collected by merely shaking the branches. It is an exudation from the leaves and branches of the plant, only appearing in hot weather in the form of drops which soon harden by exposure to the air. Camels are very fond of it. *A. mazorum*, the plant mentioned as producing it, certainly does not do so in India. The secretion is supposed by some to be identical with the manna by which the Israelites were miraculously fed. [M. T. M.]

**ALIAKOO** An Indian tree, *Momcydon tinctorius*, whose leaves are used for dyeing yellow.

**ALIBOUFIER.** (Fr.) *Silyris officinalis*.

**ALISIER.** (Fr.) *Pyrus Aria*. —DE FOR-  
TAINBLEAU. *Crataegus* or *Sorbus lasiofolia*.  
—FRANCHANT or DES BOIS. *Pyrus* for-  
*minalis*.

**ALISMA.** The typical genus of *Alismaceae*, characterised by the parallel veins of their leaves, and their unimportant flowers of three lilac petals. *A. Plantago* grows commonly in still water, and bears large smooth, taper-pointed root leaves on long stalks. These are thought to have some resemblance to the leaves of the plantain; and hence its name. The stem, which is leafless, is bluntly triangular, from two to three feet high, much branched in its upper part, and bearing numerous flowers in a loose pyramidal panicle or irregular cluster. It is mainly increased from eorm-like tubers given off from the root, which remain dormant during the winter, and contain a store of nutriment to be employed in the development of the new plant the following year. The solid part of the root contains farinaceous matter, and, when deprived of its acrid properties by drying, is eaten by the Kalmucks. From some fanciful notion that the fearful disease hydrophobia could be counteracted by water-plants, *Alisma* was idly pitched on as a specific by empirics, but is now no longer in repute. Two other species occur in Britain: one of these, *A. natans*, is a floating plant, with larger flowers than the common water plantain; the other, *A. ranunculoides*, is smaller in all its parts, and possesses no attractive qualities. [G. A. J.]

**ALISMACEAE** (*Alismoideae*), a small group of aquatic plants, with tripetaloid flowers and superior ovaries, each containing only one or two seeds. In some respects, although endogens, they much resemble ranunculaceous exogens, *Ranunculus parnassifolius*, having altogether the appearance of an *Alisma*. Although for the most part natives of the northern parts of the world, some species of *Sagittaria* and *Damasanthem* inhabit the tropics. *Alisma* and *Sagittaria* have a fleshy rhizome, which is eatable; a species of the latter genus, *S. sinensis*, is cultivated for food in China, although its herbage is acrid. Various Brazilian *Sagittarias* are very astringent; and their expressed juice is even employed in the preparation of ink. The whole number of species does not exceed fifty, divided among the genera *Alisma*, *Sagittaria*, and *Damasanthem*, which see.

**ALK.** A gum-resin obtained in North Africa from *Pistacia Terebinthus*.

**ALKANET.** The root of *Alkanna tinctoria*, which is used as a dye. Also applied in America to *Lithospermum canescens*.

**ALKANNA.** A genus of Mediterranean and Oriental *Borraginaceae*, closely allied to *Lithospermum*, of which it perhaps ought

to be considered a section, as it only differs by having the four small nuts which form the fruit contracted at the base. In habit it is, however, more like *Anchusa*, but the absence of scales closing the throat of the corolla, and the nuts not excavated at the base, are distinctive characters. The species are hispid or pubescent herbs, with oblong entire leaves and bracteated racemes, rolled up before the flowers expand. The corolla is rather small, between funnel and salver-shaped; usually purplish blue, but in some species yellow or whitish; the calyx enlarges in fruit. The root, which is often very large in proportion to the size of the plant, yields a red dye from the rind in many of the species. Alkanet, (*A. tinctoria*, *Anchusa tinctoria* of some authors, and *Lithospermum tinctorium* of others) is cultivated in Central and Southern Europe on account of this dye, which is readily extracted by oils and spirit of wine. It is employed in pharmacy to give a red colour to salves, &c., and in staining wood in imitation of rosewood, which is done by rubbing with oil in which the Alkanet root has been soaked. About eight or ten tons are annually imported from France and Germany. It is also said to be used in colouring some of the mixtures called by courtesy port wine; so it is to be feared that the whole quantity grown may not be applied to the legitimate purposes first mentioned. It is, however, perfectly harmless, which is so far satisfactory. [J. T. S.]

ALKE'KENGÉ. (Fr.) *Cardiospermum Halicababum*. — JAUNE DOUCE. *Physalis pubescens*.

ALKEKENGÍ. The common Winter Cherry, *Physalis Alkekengi*.

ALLAMANDA. A genus of *Apocynaceæ* consisting of handsome climbing shrubs, found in Brazil and other parts of South America. They are well known in gardens, where they are prized for the gorgeous profusion of their rich golden flowers. The peculiarities of the genus reside in a small five-parted calyx; a large funnel-shaped corolla, having the tube narrow and cylindrical, the limb campanulate, and then spreading out into five obtuse lobes, the throat bearing five ciliated scales; five included stamens inserted in the throat, and a one-celled compressed ovary, containing numerous ovules. There are several species. *A. Aubletii*, one of the commonest found in Guiana, is a shrub with long trailing branches, bearing whorls of oblong-lanceolate leaves, and terminal or interpetiolar many-flowered panicles of large, showy, rich yellow flowers, of which the tube is an inch long or more; and the limb forms an irregular bell, about two inches long. Another still finer species, of similar habit, *A. Schottii*, a native of Brazil, has larger flowers, which are of a full yellow, funnel-formed, the lower half, or rather less, forming a narrow contracted tube, thence suddenly expanding into a cam-

paux (throat), of a deeper yellow; the limb of five rotundate spreading segments, often with a tooth or angle on one side. *A. nerifolia*, another Brazilian species, has a more compact shrubby habit of growth, broader, more oblong leaves, and a panicle of many flowers, which are really terminal, but by and by become lateral, from innovations, or young shoots, which grow past them and terminate also in clusters of flowers. The flowers of this species have a shorter tube and a longer faux or throat, and are deep yellow, streaked with orange. Though generally producing yellow flowers, the family yields, in the *A. violacea* described by Dr. Gardner, a species with flowers of a reddish-violet colour. The genus has, moreover, a medicinal reputation; the leaves of *A. cathartica* (perhaps not different from *A. Aubletii*, already mentioned) being considered a valuable cathartic in moderate doses, especially in the cure of painters' colic, though in over-doses it is said to be violently emetic and purgative. An infusion of the leaves is used in Surinam as a remedy for colic. [T. M.]

ALLANTODIA. A genus of polypodiaceous Ferns, belonging to the *Asplenium*, among which they are distinguished by having the indusia simple and distinct; the veins of the frond reticulated, with free veinlets at the margin; and a vaulted or convex indusium. As thus defined, it includes one Indian species, *A. Brunontana*, with pinnated fronds of large size. With this are sometimes associated various free-veined species, with short tumid sori, which are not distinct from *Asplenium*. [T. M.]

ALLELUIA. (Fr.) *Oxalis Acetosella*.

ALL-GOOD. An old English name for *Chenopodium Bonus Henricus*.

ALL-HEAL. *Valeriana officinalis*. CLOWNS. *Stachys palustris*.

ALLIACEOUS. Having the smell of garlic.

ALLIAIRE. (Fr.) *Sisymbrium Alliaria*, often called *Erysimum Alliaria*, or *Alliaria officinalis*.

ALLIEZ. *Ervum Ervilia*.

ALLIGATOR WOOD. The timber of *Guarea grandifolia*.

ALLIONIA. A name given in honor of Charles Allioni, an Italian botanist, and applied to a genus of plants of the order *Nyctaginaceæ*. Some of them are cultivated as annuals in this country, though natives of central America. They are characterised by their flowers being placed within a three- or four-parted involucre; four free stamens arising from below the ovary, and included within the perianth, not projecting from it. The ovary is superior. [M. T. M.]

ALLIUM. A genus of bulbous plants of the lily family, remarkable for their pungent odour, having grassy or fistular

leaves, and star-shaped six-parted hexandrous flowers, growing in an umbel at the top of the scape. The species are numerous, very few of them ornamental; but several are cultivated as esculents.

The Onion, *A. Ceps*, has been known and cultivated as an article of food from the very earliest period. Its native country is unknown, but it is believed to have originated in the East. In the sacred writings (Numbers xi. 5) we find it mentioned as one of the things for which the Israelites longed when in the wilderness, and complained to Moses. To show how much it was esteemed by the ancient Egyptians, we need only mention that Herodotus says in his time there was an inscription on the Great Pyramid, stating that a sum amounting to 1,600 talents had been paid for onions, radishes, and garlic, which had been consumed by the workmen during the progress of its erection. Even at the present day, the people of Western Asia, as well as the inhabitants of cold countries, are all large consumers of Onions, which, for culinary purposes, are more universally cultivated than almost any other vegetable. It is distinguished from other alliaceous plants by its larger fistular leaves, swelling stalk, and coated bulbous root. The uses to which it is applied are very numerous. From the time the plants are as large as an ordinary needle, until they attain the height of five or six inches, they are chopped and mixed in salads, which, according to the witty Sydney Smith, would not be perfect without them—

'Let onions, *atoms*, lurk within the bowl,  
And, scarce suspected, animate the whole.'

When bulbing and mature, they form an indispensable component in all soups and stews; at least, Dean Swift says—

'This is every cook's opinion—  
No savoury dish without an onion;  
But lest your kissing should be spoiled,  
Your onions should be thoroughly  
boiled.'

The smaller-sized bulbs are highly prized for preserving in vinegar as a pickle. A number of varieties are cultivated, and esteemed in proportion to their being hardy, and good keepers.

The Under-ground, or Potato Onion, is supposed to be a variety of the common Onion, which it greatly resembles, but has the singular property of multiplying itself by the formation of young bulbs on the parent root, and thus produces an ample crop below the surface. Like the potato, its origin is not exactly known; but, from being sometimes called the Egyptian Onion, it is supposed to have been originally brought from Egypt about the beginning of the present century. In the West of England it is much cultivated, being quite hardy, productive, and as mild in quality as the Spanish onion.

The bulb-bearing Tree-Onion, *A. Ceps* var. *bulbiferum*, was introduced from Canada in 1820, and is considered to be a viviparous

variety of the common Onion, which it resembles in appearance. It differs in its flower-stem being surmounted by a cluster of small green bulbs, instead of bearing flowers and seed. These bulbs are very similar to small Onions, and are said to be excellent in pickles, for which their diminutive size is a great recommendation.

The Welsh Onion is *A. fistulosum*. How this obtained the name of Welsh Onion it is impossible to say, as it is a native of Siberia and certain parts of Russia, where it is known as the Rock Onion, or Stone Leek, and regarded as an article of food. It has been cultivated in this country since 1620. It never forms a bulb like the common Onion, but has long tapering roots and strong fibres. From being very hardy, it is sometimes sown to furnish small green onions for spring salads.

The Leek, *A. Porrum*, is of great antiquity, and, although said to be a native of Switzerland, and to have been introduced in 1563, we think it is far more probable that, like the Onion, it originated in the East, mention being made in the sacred writings of both having been cultivated by the Egyptians in the days of Pharaoh. According to Pliny, Leeks were brought into great notice by the Emperor Nero, and the best were produced at Aricia, in Italy. Tusser and Gerard, two of our earliest writers on gardening, speak of the Leek almost as if it were indigenous and in common use in their time. It is still very generally cultivated, not only in England, but more especially in Scotland and Wales, where it is esteemed as an excellent and wholesome vegetable. The whole plant, except the roots, is used in soups and stews. The stems are blanched by being planted deep for the purpose, and are much used in French cookery. The Leek, from time immemorial, has been regarded as the badge of Welchmen, who continue to wear it on St. David's day, in commemoration of a victory which the Welch obtained over the Saxons in the sixth century, and which they attributed to the Leeks they wore by the order of St. David to distinguish him in the battle.

The Shallot, *A. ascalonicum*, is a hardy bulbous perennial, native of Palestine, and more immediately of the neighbourhood of the once famous city of Ascalon, where Richard the First, King of England, defeated Saladin's army in 1192. It was first brought to this country in 1548. The bulbs are compound, separating into what are termed cloves, like those of garlic. They are used for culinary purposes, like onions, but are considered milder in flavour. In a raw state, they are occasionally cut very small and used to season chops or steaks; or mixed in winter salads. In French cookery, the Shallot is in great request, and several varieties are noticed by French writers, which have scarcely any other difference than that of the bulbs being larger or smaller than the ordinary size. They make an excellent pickle; and, by putting half a dozen cloves

into a quart bottle of vinegar, an agreeable sauce may be formed.

The Garlic, *A. sativum*, is a hardy bulbous perennial, indigenous to the South of France, Sicily, and the South of Europe. It is stated to have been introduced in 1548, but appears to have been well known to the ancients. Homer makes it part of the entertainment which Nestor served up to his guest Machaon; and among the Greeks and Romans we are told it formed a favourite viand of the common people. Even at the present day, in many parts of the Continent the peasantry eat their brown bread with slices of Garlic, which give it a flavour they seem to relish. At Ovar, in Portugal, a great deal of this root is grown for exportation to Brazil. The bulb is compound, being composed of ten or twelve smaller bulbs, called cloves; and, although seldom employed with us, it is much used in Italian cookery for flavouring dishes, and is far more powerful for this purpose than any of the other species.

The common Chive or Clive, *A. Schanoprasum*, is indigenous to Britain, having been found in Oxfordshire, as well as in Argyleshire, in the West of Scotland. It is perennial. The leaves, which rise from small slender bulbs, are about six or eight inches long, erect, awl-shaped and thread-like, and form dense tufts. They are generally cut off close to the ground, and used early in spring for salads, for which purpose they are much milder than onions or scallions—a name usually given to onions which have been sown thick for drawing, without forming bulbs. They are also used for seasoning soups, omelets, &c. In England they are little known; but in Scotland they are to be found in almost every cottage garden.

Rocambole, *A. Scorodoprasum*, is a native of Denmark and other parts of Europe, whence it was introduced in 1596. It is a hardy, bulbous-rooted perennial, with compound bulbs like garlic, but the cloves are smaller. It is used for nearly the same purposes as the shallot and garlic; and, although its flavour is considered more delicate than either, it is not much cultivated in this country. [W. B. B.]

**ALLOBIMUM.** A genus of *Viscaceæ*, consisting of yellowish-green woody parasites on the branches of trees, with jointed, much-branched stems; thick firm persistent leaves, or only scales in their place; and small axillary spikes of flowers. The flowers are dioecious; the calyx is globular and three-lobed, each lobe in the male flowers bearing a transversely two-celled sessile anther; in the female flowers the calyx tube adheres to the ovary, which has a sessile obtuse stigma. The ovary contains a single pulpy seed, with a small embryo. The species of this genus are natives of America. [W. C.]

**ALLOPLECTUS.** A genus of *Geenaceæ*, distinguished by having a free, coloured, five-leaved calyx; a funnel-shaped or club-tubulose corolla, with the tube gibbous at

the base behind, and often ventricose in front above, the limb five-toothed or shortly five-cleft; four didynamous included stamens, with the rudiment of a fifth; and a free ovary surrounded by an annular disk. The genus consists of tropical American soft-wooded or sub-shrubby plants, of scandent habit, with opposite, fleshy, often unequal leaves, and axillary flowers which are solitary or aggregated, sessile or racemose. There are several species, most of which form desirable hot-house plants. *A. dichrous* is a Brazilian sub-shrub, of erect habit, with ovate-oblong entire leaves, having several flowers seated in their axils; these flowers consist of a large purple-red calyx of five triangular or cordate lobes, the three outer of which are larger and include the two inner, and of a large club-shaped tubular yellow hairy corolla, the colour of which contrasts strongly with that of the calyx. *A. concolor* is of similar habit, but has rather smaller flowers, of which both calyx and corolla are scarlet. The corolla in this latter plant is inserted at what appears to be the side of the tube near the base, and thus forms a blunt spur, whilst above it is remarkably ventricose on the upper side, with the mouth very oblique, as if the opening were at the side opposite to that by which it is affixed, thus producing a very singularly curved flower. *A. capitatus* is very distinct from the foregoing kinds, having tall stout red stems and large ovate leaves, from which the axils of the uppermost leaves are produced on short stalks, a few dense globular heads or umbels of flowers, having a very large blood-coloured calyx, and a comparatively small yellow tubular corolla. The most remarkable peculiarity of the genus among generaceous plants, is the large coloured calyx, which adds much to the beauty of the flowers. [T. M.]

**ALLOSORUS.** A genus of dwarf elegant polypodiaceous Ferns, variously referred to the *Polypodieæ*, the *Cheilantheæ*, and the *Pteridæ*. They have punctiform sori at the apices of the free veins, and are without true indusia, the margin of the fronds being folded over the sori cases and somewhat altered in texture, so as to become indusia. Added to this, their fronds are dimorphous, the fertile and sterile being different in character, the former contracted by the involution of their margins, so that the divisions become pod-shaped or siliciform. One of the species, *A. crispus*, is a native of England, and is found also throughout Europe and in North America. This is a pretty dwarf deciduous species, with bipinnate or tripinnate fronds. It is called the Rock Brake. There is another species, *A. Stelleri*, found in Siberia, India, and North America. The genus has a very close affinity with *Cryptogramma*. The name has been applied to various other ferns, especially to certain species which are more correctly referred to *Cheilanthes* and *Platy-loma*. [T. M.]

ALLOUCHIER. (Fr.) *Pyrus Aria*.

ALLSEED. The common name for *Polycarpon*. Also sometimes applied to *Che-nopodium polyspermum*, and *Radiola Mil-legrana*.

ALLSPICE. The fruit of *Eugenia Pi-mentia*. — CAROLINA. *Calycanthus floridus*. — JAPAN. The common name for *Chimo-nanthus*. — WILD. *Benzoin odoriferum*.

ALLSPICE TREE. The common name for *Calycanthus*.

ALLUBODON, ALUBO. The wood of *Calyptanthus Jambolana*, a common building material in Ceylon.

ALMEIDIA. The founder of this genus of Eutaceous trees has devoted it to a Portuguese nobleman who assisted him in prosecuting his botanical researches in Brazil. The genus is allied to *Diosma*, but is known by its five equal, spoon-shaped petals, five fertile distinct stamens with flattened hairy filaments, an hypogynous cup-shaped disc, and a fruit opening by two valves. *A. rubra* is a handsome shrub with rose-coloured flowers, sometimes seen in hot-houses. [M. T. M.]

ALMOND. The fruit of *Amygdalus com-munis*; the Bitter and Sweet Almonds are the produce of different varieties of this species. — AFRICAN. *Brachyum stellati-folium*. — COUNTRY. The fruit of *Ter-minalia Catappa*. — JAVA. *Canarium commune*.

ALMOND-WORTS. An English name proposed for the group *Drupaceae*.

ALNUS. A family of trees belonging to the natural order *Betulaceae*, and all more or less approaching in character the common Alder, *A. glutinosa*. They inhabit most temperate countries of the northern hemisphere, and delight in a moist soil. The common Alder, in its young state, is a bushy shrub of a pyramidal form, heavily clothed with dark green leaves, which, as well as the young shoots, are covered with a glutinous substance. The leaves are stalked, roundish, blunt, jagged at the edge, shining above, and furnished at the angles of the veins beneath with minute tufts of whitish down. The flowers are of two kinds; the barren are long drooping catkins, which appear in the autumn and hang on the tree all the winter; and the fertile are oval, like little fir-cones, but are not produced till spring. When these ripen, the thick scales of which they are composed separate, and allow the seeds to fall, but remain attached to the tree themselves all the winter, and by them the tree may be distinguished when stripped of all its leaves. In young trees the bark is smooth and of a dark purple-brown hue, but in old trees it is rugged and nearly black. When allowed to attain its full growth, it reaches a height of forty or fifty feet, if the situation be favourable; but in the mountains and in high latitudes it does not rise above a shrub. The wood of the Alder is soft

and light; and if exposed alternately to wet and dry, will scarcely last a year; but if kept entirely submerged, or buried in damp earth, no wood is more durable. By lying for a long time in peat bogs, it acquires a black hue, but from its softness will not take a good polish. The young branches are much used for the purpose of filling in drains, and are more durable than any other kind of brushwood. The charcoal is highly valued in the manufacture of gun-powder, for which purpose it is in some places largely planted. The colour of the wood when first cut is white, but by exposure it becomes of a bright orange-red, as is shown by the chips which are left about where a tree has been felled. Several varieties are grown which differ from the typical species in having laciniated, lobed, or variegated leaves. Of the other species enumerated by Loudon, *A. cordifolia*, a native of Italy, is well adapted to this climate. It grows with rapidity, and is a most interesting and ornamental tree. The common Alder is the badge of the clan Chisholm. [C. A. J.]

ALOCASTA. A name applied to a section of the genus *Colocasia*, by some considered as a distinct genus. The species are natives of India, with peltate leaves springing from an erect root-stock; spathes glaucous, on short stalks. [M. T. M.]

*A. metallica* is a magnificent Bornean species, with very large cordate-ovate peltate leaves, having a rich bronze-coloured surface, and is a very conspicuous ornament of our hot-houses. The leaves look like great polished metal shields. [T. M.]

ALOE. A Latinised form of an Arabic name given to a genus of succulent plants of the Lily family (*Liliaceae*). The species of the genus vary very much in height, and in the appearance of their leaves and flowers, but are especially distinguished from allied genera by their having a stem, sometimes a very short one; permanent fleshy leaves; flowers arranged in erect spikes or clusters, each with a cylindrical perianth divided into six pieces, secreting nectar at the base; six stamens arising like the perianth from below the germen; a membranous fruit, consisting of three cells, each containing a great number of seeds. The species of Aloe are abundant in all warm countries, especially in the southern part of Africa and the Isle of Socotra, where 'the bristling aloes' give a character of their own to the landscape.

*A. vulgaris*, a native of the East and West Indies has been introduced into Italy, Sicily, Malta, and the Mediterranean region in general. The most important product of this genus is the drug known as aloes, which is the dried juice derived from the leaves of several species in the East and West Indies, Cape of Good Hope, and elsewhere. The finest kind of aloes is supposed to be derived from *Aloe socotrina*. The bitter resinous juice is stored up in greenish vessels, lying beneath the skin of the leaf, so that when the leaves are cut transversely, the juice exudes and is gradu-

ally evaporated to a firm consistence. The inferior kinds of aloes are prepared by pressing the leaves, when the resinous juice becomes mixed with the mucilaginous fluid from the central part of the leaves, and becomes proportionately deteriorated. In other cases the leaves are cut in pieces and boiled, and the decoction evaporated to a proper consistence.

The drug is imported in chests, in skins of animals, and sometimes in the cavity of large calabash gourds. It is largely used as a purgative, and in small doses as a tonic; the taste is peculiarly bitter and disagreeable, though the perfume of the finer sorts, when breathed on, is aromatic, and by no means so offensive as the taste. What is called aloes fibre seems rather to be the produce of an *Agave*, though it is stated that the negroes of Western Africa make nets and cords of the fibres of various species of *Aloe*.

Many of the species of *Aloe* are cultivated in this country, being extremely easy to grow, if planted in a dry soil and very little if any water supplied to them in the winter season. The thick leathery skin of the leaves prevents the internal moisture from escaping so readily, hence these plants retain their vitality for a long time under apparently adverse circumstances.

*Aloe ferax.*

Sailors sometimes bring home pieces of Aloe from the West Indies with a tarred cloth tied tightly round the cut end, so as to prevent the escape of the juices. Dr. Pereira mentions having had such a specimen suspended from the ceiling of his room for two years, and it was still living and growing when he wrote.

What is commonly known as the Ame-

rican Aloe is a species of *Agave* much like an *Aloe* in general appearance, but particularly distinguished from it by the perianth being adherent to the ovary, or, as it is called, superior. [M. T. M.]

**ALOE, AMERICAN.** *Agave americana*.  
**—FALSE.** *Agave virginica*.

**ALOE'S BEC DE CANNE.** (Fr.) *Aloe*, or *Gasteria disticha*. — **CORNE DE BE'LIER.** *Aloe arborescens*. — **LANGUE-DE-CHAT.** *Aloe* or *Gasteria lingua* and *angulata*. — **POUCE-E'CRASE.** *Aloe retusa*.

**ALOES-WOOD.** The wood of *Aloexylon Agallochum*.

**ALOEXYLON.** The name of a genus described by Loureiro, and doubtfully referred to *Leguminosae*, which is said to grow on the high mountains of Cochinchina. There is but one species, *A. Agallochum*, which is described as being a tree of about sixty feet in height, with simple, alternate, stalked, entire, lanceolate leaves, and terminal panicles of small flowers. The wood of this tree is one of the two woods known as Calambac, Lign-aloes or Eagle-wood. It yields the perfume the most esteemed by Orientals, who apply it to their clothes and apartments, and use it in medicine, in the treatment of paralytic affections. The perfume by some is said to originate by the concoction of oily particles into a resin; which action takes place in the centre of the trunk, and is occasioned by a disease which ultimately causes the death of the tree. This is, however, questioned by others. The wood is very valuable—selling at about 80¢ per cwt. in Sumatra. It is sometimes used for inlaying in cabinet work. Some of the most precious jewels of East Indian manufacture are set in it; and, so highly is it prized, that it is considered equal to gold in point of value. The perfume derived from it is thought by some to be alluded to in the Bible, where it is said (Psalm xlv. 8), 'All thy garments smell of myrrh, aloes, and cassia.' The wood is said to retain its fragrance for years. Many conflicting statements have been published about this tree, and the *Aquilaria Agallocha*, which is also called Eagle-wood, and belongs to a very different family; and it is possible that some of the statements above given may apply to the *Aquilaria* rather than to the plant under consideration, which is, botanically almost unknown. [A. A. B.]

**ALONA.** A small genus of South American *Nolanaeae*, separated from *Nolana* by having several ovaries, with from one to six cells (not five, each of them four-celled, as in *Nolana*). Mr. Miels restricts the genus *Alona* to the species with woody stems and fasciculate terete or trigonous leaves, as he finds that, in the allied genus *Sorema*, the way in which the carpels are combined varies in the same genus, and therefore cannot by itself be sufficient to make a generic distinction. The species have large handsome flowers, resembling those of the bindweeds. *A. ciliolata* is cultivated

**ALLOUCHIER.** (Fr.) *Pyrus Aria*.

**ALLSEED.** The common name for *Polycarpon*. Also sometimes applied to *Onopodium polyspermum*, and *Radiola Millegreana*.

**ALLSPICE.** The fruit of *Eugenia Pi-mentia*. — **CAROLINA.** *Calycanthus floridus*. — **JAPAN.** The common name for *Chimonanthus*. — **WILD.** *Benzoin odoriferum*.

**ALLSPICE TREE.** The common name for *Calycanthus*.

**ALLUBODON, ALUBO.** The wood of *Calyptanthus Jambolana*, a common building material in Ceylon.

**ALMEIDIA.** The founder of this genus of Eutaceae trees has devoted it to a Portuguese nobleman who assisted him in prosecuting his botanical researches in Brazil. The genus is allied to *Diosma*, but is known by its five equal, spoon-shaped petals, five fertile distinct stamens with flattened hairy filaments, an hypogynous cup-shaped disc, and a fruit opening by two valves. *A. rubra* is a handsome shrub with rose-coloured flowers, sometimes seen in hot-houses. [M. T. M.]

**ALMOND.** The fruit of *Amygdalus communis*; the Bitter and Sweet Almonds are the produce of different varieties of this species. — **AFRICAN.** *Brabejum stellatifolium*. — **COUNTRY.** The fruit of *Terminalia Catappa*. — **JAVA.** *Canarium commune*.

**ALMOND-WORTS.** An English name proposed for the group *Drupaceae*.

**ALNUS.** A family of trees belonging to the natural order *Betulaceae*, and all more or less approaching in character the common Alder, *A. glutinosa*. They inhabit most temperate countries of the northern hemisphere, and delight in a moist soil. The common Alder, in its young state, is a bushy shrub of a pyramidal form, heavily clothed with dark green leaves, which, as well as the young shoots, are covered with a glutinous substance. The leaves are stalked, roundish, blunt, jagged at the edge, shining above, and furnished at the angles of the veins beneath with minute tufts of whitish down. The flowers are of two kinds; the barren are long drooping catkins, which appear in the autumn and hang on the tree all the winter; and the fertile are oval, like little fir-cones, but are not produced till spring. When these ripen, the thick scales of which they are composed separate, and allow the seeds to fall, but remain attached to the tree themselves all the winter, and by them the tree may be distinguished when stripped of all its leaves. In young trees the bark is smooth and of a dark purple-brown hue, but in old trees it is rugged and nearly black. When allowed to attain its full growth, it reaches a height of forty or fifty feet, if the situation be favourable; but in the mountains and in high latitudes it does not rise above a shrub. The wood of the Alder is soft

and light; and if exposed alternately to wet and dry, will scarcely last a year; but if kept entirely submerged, or buried in damp earth, no wood is more durable. By lying for a long time in peat bogs, it acquires a black hue, but from its softness will not take a good polish. The young branches are much used for the purpose of filling in drains, and are more durable than any other kind of brushwood. The charcoal is highly valued in the manufacture of gunpowder, for which purpose it is in some places largely planted. The colour of the wood when first cut is white, but by exposure it becomes of a bright orange-red, as is shown by the chips which are left about where a tree has been felled. Several varieties are grown which differ from the typical species in having lacinated, lobed, or variegated leaves. Of the other species enumerated by London, *A. cordifolia*, a native of Italy, is well adapted to this climate. It grows with rapidity, and is a most interesting and ornamental tree. The common Alder is the badge of the clan Chisholm. [C. A. J.]

**ALOCASIA.** A name applied to a section of the genus *Colocasia*, by some considered as a distinct genus. The species are natives of India, with peltate leaves springing from an erect root-stock; spathes glaucous, on short stalks. [M. T. M.]

*A. metallica* is a magnificent Bornean species, with very large cordate-ovate peltate leaves, having a rich bronze-coloured surface, and is a very conspicuous ornament of our hot-houses. The leaves look like great polished metal shields. [T. M.]

**ALOE.** A Latinised form of an Arabic name given to a genus of succulent plants of the Lily family (*Liliaceae*). The species of the genus vary very much in height, and in the appearance of their leaves and flowers, but are especially distinguished from allied genera by their having a stem, sometimes a very short one; permanent fleshy leaves; flowers arranged in erect spikes or clusters, each with a cylindrical perianth divided into six pieces, secreting nectar at the base; six stamens arising like the perianth from below the germen; a membranous fruit, consisting of three cells, each containing a great number of seeds. The species of Aloe are abundant in all warm countries, especially in the southern part of Africa and the Isle of Socotra, where 'the bristling aloes' give a character of their own to the landscape.

*A. vulgaris*, a native of the East and West Indies has been introduced into Italy, Sicily, Malta, and the Mediterranean region in general. The most important product of this genus is the drug known as aloes, which is the dried juice derived from the leaves of several species in the East and West Indies, Cape of Good Hope, and elsewhere. The finest kind of aloes is supposed to be derived from *Aloe spicata*. The bitter resinous juice is stored up in greenish vessels, lying beneath the skin of the leaf, so that when the leaves are cut transversely, the juice exudes and is gradu-

ally evaporated to a firm consistence. The inferior kinds of aloes are prepared by pressing the leaves, when the resinous juice becomes mixed with the mucilaginous fluid from the central part of the leaves, and becomes proportionately deteriorated. In other cases the leaves are cut in pieces and boiled, and the decoction evaporated to a proper consistence.

The drug is imported in chests, in skins of animals, and sometimes in the cavity of large calabash gourds. It is largely used as a purgative, and in small doses as a tonic; the taste is peculiarly bitter and disagreeable, though the perfume of the finer sorts, when breathed on, is aromatic, and by no means so offensive as the taste. What is called aloes fibre seems rather to be the produce of an *Agave*, though it is stated that the negroes of Western Africa make nets and cords of the fibres of various species of *Aloe*.

Many of the species of *Aloe* are cultivated in this country, being extremely easy to grow, if planted in a dry soil and very little if any water supplied to them in the winter season. The thick leathery skin of the leaves prevents the internal moisture from escaping so readily, hence these plants retain their vitality for a long time under apparently adverse circumstances.

*Aloe ferax.*

Sailors sometimes bring home pieces of Aloe from the West Indies with a tarred cloth tied tightly round the cut end, so as to prevent the escape of the juices. Dr. Pereira mentions having had such a specimen suspended from the ceiling of his room for two years, and it was still living and growing when he wrote.

What is commonly known as the Ame-

rican Aloe is a species of *Agave* much like an *Aloe* in general appearance, but particularly distinguished from it by the perianth being adherent to the ovary, or, as it is called, superior. (M. T. M.)

**ALOE, AMERICAN.** *Agave americana*.  
—**FALSE.** *Agave virginica*.

**ALOE'S BEC DE CANNE.** (Fr.) *Aloe*, or *Gasteria disticha*. — **CORNE DE BE'LIER.** *Aloe arborescens*. — **LANGUE-DE-CHAT.** *Aloe* or *Gasteria Kingia* and *angulata*. — **POUCE-E'CRASE.** *Aloe retusa*.

**ALOE-WOOD.** The wood of *Alcockylon Agallochum*.

**ALOEXYLON.** The name of a genus described by Loureiro, and doubtfully referred to *Leguminosae*, which is said to grow on the high mountains of Cochín China. There is but one species, *A. Agallochum*, which is described as being a tree of about sixty feet in height, with simple, alternate, stalked, entire, lanceolate leaves, and terminal panicles of small flowers. The wood of this tree is one of the two woods known as Calambac, Lign-aloes or Eagle-wood. It yields the perfume the most esteemed by Orientals, who apply it to their clothes and apartments, and use it in medicine, in the treatment of paralytic affections. The perfume by some is said to originate by the concoction of oily particles into a resin; which action takes place in the centre of the trunk, and is occasioned by a disease which ultimately causes the death of the tree. This is, however, questioned by others. The wood is very valuable—selling at about 30*l.* per cwt. in Sumatra. It is sometimes used for inlaying in cabinet work. Some of the most precious jewels of East Indian manufacture are set in it; and, so highly is it prized, that it is considered equal to gold in point of value. The perfume derived from it is thought by some to be alluded to in the Bible, where it is said (Psalm xiv. 8), 'All thy garments smell of myrrh, aloes, and cassia.' The wood is said to retain its fragrance for years. [A. A. B.]

**ALONA.** A small genus of South American *Nolanaeae*, separated from *Nolana* by having several ovaries, with from one to six cells (not five, each of them four-celled, as in *Nolana*). Mr. Miers restricts the genus *Alona* to the species with woody stems and fasciculate terete or triquetrous leaves, as he finds that, in the allied genus *Sorema*, the way in which the carpels are combined varies in the same genus, and therefore cannot by itself be sufficient to make a generic distinction. The species have large handsome flowers, resembling those of the bindweeds. *A. caulescens* is cultivated

in this country for the beauty of its large pale blue flowers. It is a native of the coast of Chili.

[J. T. S.]

**ALONSOA.** A small group of the *Scrophulariaceae*, forming dwarf frutescent herbs, with opposite or ternately whorled serrated leaves, and axillary, subracemose, pretty vermilion-coloured flowers. They are commonly cultivated in green-houses, and in the open air during summer. The characteristic features are a five-parted, sub-equal calyx; a resupinate corolla, having a very short tube, and a sub-rotate, five-cleft limb, of which the front, or upper lobe, is larger, and all rotundate; four didynamous declinate exserted stamens, affixed to the corolla tube; and a two-celled many-seeded ovary. The few species are mostly natives of Peru, where one of the species is famed for its anodyne and stomachic properties; and several of them have been introduced to our gardens. *A. linearis*, a pretty dwarf, bushy, suffrutescent plant, of a span or foot in height, has the leaves, which are narrow linear, opposite or in threes, mostly fasciculate, from the non-evolution of the axillary shoots; and the branches terminate in racemes of curious, obliquely-rotate scarlet flowers, with a black spot at the base. In Peru it is called *Ricaco* and *Ricarco*, which mean Mask-flower. One of the best known species, *A. maculifolia* (sometimes called *Celastris arcticaefolia*), has ovate, acute, deeply-toothed leaves, and elongated racemose spikes of scarlet and black flowers. *A. Warszewiczii*, obtained from the mountains of Peru, has racemes of scarlet flowers, without the black spot which is conspicuous in the other species already noticed. Both are erect branched subshrubby plants. There are about a dozen described species.

[T. M.]

**ALOPECURUS.** A genus of Grasses called Fox-tail Grasses, of the tribe *Poaceae*, distinguished from *Phleum*, to which some of the species are nearly allied, by having only one inner glume or pale to each flower, this bearing a long awn attached to the back portion of it. The species are mostly from temperate climates, and have an extensive range from their southern to their northern limits. Among those which are natives of Britain, the meadow Fox-tail Grass is one of the very best kinds, and forms a portion of all good pastures and meadows—particularly on limestone soils: the seeds are consequently sown in most instances as part of a mixture of grass seeds. It is one of the earliest kinds to flower in spring, and, when chemically analysed, is found to contain a large share of nutritive matter in its composition. The other species which are natives of Britain are of less agricultural value. The alpine Fox-tail Grass (*Alopecurus alpinus*) is one of the rarest native species, being much prized and eagerly sought after as a botanical rarity.

[D. M.]

**ALOYSIA.** The genus to which the lemon-scented Verbena (*V. triphylla*), is sometimes referred.

**ALPHONSEA.** Certain Indian plants are comprised in a genus bearing the above name, in honour of M. Alphonse de Candolle, the eminent botanist who has especially studied the natural order *Anonaceae*, to which this genus belongs. Its principal characters are—petals valvate in the bud, nearly equal in size; stamens loosely imbricate. By these circumstances the genus may be distinguished from its nearest ally, *Saccolatum*. The species comprise tall trees furnished with thick shining leaves, and small flowers, closely packed in tufts opposite to the leaves.

[M. T. M.]

**ALPINIA.** A genus of plants deriving its name from Prosper Alpinus, an Italian botanist who lived in the 16th century. The genus belongs to the same natural family as the ginger (*Zingiberaceae*), and is known by its thick, tuber-like, aromatic rhizomes; and by its flowers arranged in terminal spikes. Each flower has an outer row of three pieces, and an inner of four pieces, the lowermost of which is three-lobed. The filament is petal-like, and not prolonged beyond the two-lobed anther, as in some of the plants of this order. Stigma triangular, on a long style. The fruit is a somewhat fleshy capsule of three many-seeded cells. The species are natives of tropical America, the Indian Archipelago, etc. *A. Galanga* and other kinds furnish the aromatic stimulant root known as Galangale root, employed by the natives in cases of indigestion. The fruits of *A. alba* are known as ovoid China Cardamoms; others, as *A. nutans*, are remarkable for the exceeding beauty of their flowers, and are therefore cultivated in our stoves.

[M. T. M.]

**ALPISTE.** (Fr.) *Phalaris canariensis*.

**ALSINE.** A genus of small Caryophyllaceous herbs, generally distributed in temperate regions, and in alpine situations in warmer climates; closely resembling *Arenaria*, from which it differs by having the valves of the capsule equal in number to the styles, and not twice as many. The leaves are generally narrow, often subulate; the sepals strongly nerved; the petals white. Four species are natives of Britain: *A. verna*, a tufted perennial, with the petals longer than the calyx; *A. rubella*, a tufted alpine perennial, with short flower-stalks, and the petals not exceeding the calyx; *A. uliginosa*, also tufted perennial, with the petals scarcely exceeding the calyx, but with long pedicels and smaller flowers than the last; and *A. tenuifolia*, a slender annual, not uncommon on wall tops and on dry commons in the South-east of England.

[J. T. S.]

**ALSODEIA.** A genus of ornamental plants, belonging to the order *Violaceae*, and inhabiting the islands of Madagascar and Timor. Some of the species are cultivated in this country. They are distinguished by their petals being all equal in size; by the absence of scales between the petals and stamens; the stamens spring from a disc surrounding the base of the

ovary, free above; filament dilated, not narrowed into a claw. They are woody plants, with white flowers, and thickly beset with leaves; hence the name—from the Greek *alodes*, leafy. [M. T. M.]

**ALSOPHILA.** A genus of cyatheaceous Ferns, representing the *Alsophytes*: often becoming magnificent unbranched trees. Among the cyatheaceous Ferns, which are known by the obliquity of the ring of their spore-cases, and by having an elevated receptacle, *Alsophila* is distinguished, primarily, by the absence of any indusium or cover to the sorus; and, secondarily, by producing only one sorus on each vein or venule. There are a considerable number of species, some of which have been imported for the decoration of our hot-houses. The species have bipinnate fronds, and a considerable number of them are found in the West Indies, South America, and Mexico, a few in Australia and the South Sea Islands, and several more in the East Indies and Malay Islands. *A. excelsa*—a native of Norfolk Island—is stated by Capt. King to grow to a height of eighty feet. 'The branches (fronds), which resemble those of the palm-tree in their growth, fall off every year, leaving an indentation on the trunk. The middle of the tree, from the root to the apex, consists of a white substance, resembling a yam, which, when boiled, tastes like a bad turnip: this the hogs feed on greedily. The outside of the trunk is hard wood, and full of regular indentations, from the top to the bottom.' Another tree of the same genus, cut down by Mr. Allan Cunningham, was fifty-seven feet long without the fronds; and Mr. Backhouse measured some forty feet high, crowned with magnificent circular crests of fronds. It is altogether a noble plant, having the stipes and main rachis of its fronds muricate, or rough, with small raised points. The fronds are bipinnate; the pinnae, or secondary divisions, oblong-lanceolate, acuminate, pinnatifid, with oblong acutish segments. *A. australis*, from the same region, is another fine species. In Tasmania, where Mr. Backhouse met with tree ferns in profusion, this species was seen with stems of all degrees of elevation up to twenty-five or thirty feet, some of them at the lower part as stout as a man's body, the whole length clothed with the bases of old leaves, which were rough, like the stems of raspberries, closely tied over each other, and pointing upwards. Some of the larger fronds were thirteen feet long—making the diameter of the crest twenty-six feet. Some of the Indian species are also remarkable for their stature. There is preserved in the British Museum a stately trunk, forty-five feet long, of *A. Brunonian*; and another of equal height, belonging to *A. gigantea*, is in the museum of the Linnean Society of London. Some of the species are, however, without these elongated trunks, although all produce fronds of large size. [T. M.]

**ALSOPHILEÆ.** A section of cyatheæ-

ous Ferns, in which the sort have no cover. The plants referred to here are sometimes not easily distinguished from *Polypodium*, the compression of the spore cases being less marked, and the receptacle less obviously elevated than in the more typical species. [T. M.]

**ALSTONIA.** A genus of the Periwinkle family (*Apocynaceæ*) differing from most others in the seeds having a tuft of silky hairs at each end, instead of at one end only; and from its nearest ally, *Blaberopus*, in the absence of the two nectary scales seen in the flowers of that genus. There are about a dozen species distributed over India, the Moluccas, tropical Australia, and West Africa. They are trees or shrubs with milky juice; opposite, often whorled, and entire leaves; small white flowers disposed in cymes at the ends of the branches, the corolla funnel-shaped with a flat border of five rounded lobes; and fruits consisting of two cylindrical pods (*follicles*) the thickness of a quill, and often a foot in length.

*A. scholaris*, called Devil-tree or Palt-mara about Bombay, is a widely-diffused plant in India and the Moluccas. It is a tree of fifty to eighty feet, with a furrowed trunk; oblong stalked leaves, three to six inches long, and two to four wide, disposed in whorls of four to six round the stem, their upper surface glossy, the under white, and marked with nerves running at right angles to the midrib. It has a powerfully bitter bark, which is used by the natives in India in bowel complaints, and its light wood is used in Ceylon for making coffins. The wood taken from near the root of what appears to be the same species in Borneo, is of a white colour, very light, and used for floats for nets, and household utensils, as trenchers, corks, &c. The genus bears the name of Alston, once Professor of Botany at Edinburgh. [A. A. B.]

**ALSTRÖMERIA.** A genus of very handsome Amaryllidaceous plants, distinguished by having a six-parted regular subcampanulate perianth, of which the interior segments are narrower, and two of them somewhat tubulose at the base; six stamens inserted with the perianth; a trifid stigma; and an inferior three-celled ovary with many horizontal ovules. They are tropical or extra-tropical herbs of South America, with fasciculate tuberous roots, and erect leafy stems, terminating in umbels of showy flowers. The numerous species, many of which have ornamented our gardens, are very similar in character. The leaves in this genus are, by the twisting of the petiole, resupinate; the upper surface, which is usually smooth, even, and destitute both of ribs and stomata, having the peculiar structure and performing the functions of the under surface. This curious economy in the leaves of *Alströmeria* was first pointed out by the late Robert Brown. Amongst the handsomest of the species may be mentioned *A. aurea*, an erect herb one to three feet high, with scattered, lanceolate, obtuse leaves, reversed, as is the

case throughout the genus, by the twisting of the foot stalk. The flowers are produced several in a terminal umbel, the perianth consisting of three outer spatulate, deep orange-coloured segments, and three inner ones, which are narrower, lanceolate, acuminate, orange-coloured, the two upper of them marked with several dark red lines distributed over their surface. Quite distinct from this is *A. Flos Martini*, the St. Martin's Flower of Chili, which has an erect stem, linear acute leaves, and a perianth consisting of three outer cuneately obovate yellowish-white segments, and an inner series of one short lower whitish lobe, and two upper oblong spatulate ones which are bright yellow in the upper half, and stained with irregular dark red spots, the spots becoming confluent towards the top. *A. Ligta*, so named because, according to Feuillée, it is called *Ligta* in Chili, is another very beautiful kind, in which the leaves are linear or linear-lanceolate, and the flowers, on corymbose two-flowered peduncles, are large, bluish-coloured, with obovate emarginate sepaline divisions, the two upper petaline divisions narrow spatulate, yellow, striped with red below, and tipped with crimson. *A. patinacea* has the flowers a little hooded, rich crimson at the base, and at the tips green, spotted with purple. Another fine ornamental species is *A. Simsiana*, which has orange-scarlet flowers. The greater number of the species are natives either of Chili or of the Andes of Peru, a few being distributed in other parts of South America. The *A. patinacea* turns in Chili a kind of arrow-root, which is prepared from its succulent roots. See also *DOMARUA*. [T. M.]

**ALTERNATE.** Placed on opposite sides of an axis on a different level, as in alternate leaves. Placed between other bodies of the same or different whorls, as in an umbellifer, where the stamens are alternate with, that is between, the petals.

**ALTERNATIVE.** A term applied to mutilation, when of the pieces of a flower, being in two rows, the inner is so covered by the outer that each exterior piece overlaps half two of the interior row.

**ALTHÆA.** The Marsh-Mallow is, as the name implies, one of the *Malvaceæ*, and is distinguished by its flowers having an outer calyx of from six to nine pieces, and an inner one, partly divided above into five pieces. In other respects *Althæa* much resembles *Malva*. *A. officinalis*, the common Marsh Mallow, grows in marshes near the sea in this country, and also in Central and Southern Europe. The rootstock is perennial; the flowering stems are erect, branched, three or four feet high, covered with a soft velvety down, as also are the stalked, egg-shaped, cordate leaves, which are slightly notched at the margin, the lower ones five-lobed, the upper ones three-lobed. The flowers are of a pale rose colour, on short stalks, which spring from the axis of the upper leaves. The roots are much used, especially in France, under the

name of Guimauve, to form demulcent drinks. *A. hirsuta* is a rare English plant, which has been probably introduced along with foreign agricultural seeds. It is an erect slender annual, much smaller than the preceding, with bright pink flowers, and covered with long spreading stiff hairs. *A. rosea* is the origin of the Hollyhock of gardens. It grows wild in China, also in the South of Europe. It possesses similar properties to the common marsh mallow, and is used for similar purposes in Greece. The leaves furnish a blue dye. Several species of *Althæa* are in cultivation, but the gay flowering shrub commonly called *Althæa frutes* is, properly speaking, a species of *Hibiscus* (*syriacus*). [M. T. M.]

**ALTHÆA FRUTEX.** The garden name for *Hibiscus syriacus*.

**ALTHÆA.** (Fr.) *Althæa officinalis*.

**ALTHENIA.** A genus of *Naiadaceæ*, containing a single species, a native of France. It is a slender tufted plant, growing in salt lakes, and resembling *Zannichellia*—except that that genus has male and hermaphrodite flowers; whereas, in *Althenia*, the flowers are dioecious; the male flowers being solitary, and below the female. [W. C.]

**ALTINGIACEÆ.** (*Liquidambar, Balsamaceæ, Balsamifluæ.*) A solitary genus, *Liquidambar*, represents this natural order, of which three species only are known—of trees of some magnitude—producing a fragrant resin called storax, or resembling that substance. They are nearly related to plane-trees and willows, from which they differ in having seed vessels with two distinct cells, instead of one; and seeds with broad membranous wings. See *LIQUIDAMBAR* and *STORAX*.

**ALUM ROOT.** The root of *Geranium maculatum*; also applied to some species of *Heuchera*.

**ALUYNE.** (Fr.) *Artemisia Absinthium*.

**ALVEOLATE.** Socketed, honey-combed; when a flat surface is excavated into conspicuous cavities, as in the receptacles of many Compositæ.

**ALVIER, ALVIES.** (Fr.) *Pinus Cembra*.

**ALYSSUM.** The generic name of several herbaceous annual plants with yellow flowers, belonging to the *Cruceæ* order, and generally employed in decorating rock-work, or the open border. *A. exaltate*, a native of Transylvania, &c., popularly known as Gold-dust—in French, *Corbeille d'Or*—has somewhat woody, diffuse stems, lanceolate, hoary leaves, and numerous small flowers of a brilliant yellow colour, growing in dense clusters. These appear early in May, when flowers are scarce, and are consequently much prized. This species, like the rest of the family, thrives best in dry, somewhat stony ground; but may be made to grow anywhere. Several other species are cultivated, under the name of Madwort. [C. A. J.]

**ALYSSUM, SWEET.** *Glyce* (or *Königa*) *maritima*.

**ALYXIA.** A genus of *Apocynaceæ*, containing sixteen species; natives of Australasia, Madagascar, and tropical Asia. They consist of evergreen trees or shrubs, with ternate, quaternate, or sometimes opposite, entire, and shortly-petiolate leaves. The flowers are fragrant, axillary or terminal and solitary, or in cymes. The calyx is five-partite; the corolla is hypocrateriform, its long tube is swollen above the middle; the five included stamens, on short filaments, and with lanceolate anthers, are inserted on the dilated portion of the tube; there are two ovaries, with a single included style. While this genus has all the habit and the structure of the flowers of the true *Apocynaceæ*, it differs from the other genera of the order in having baccate, or sub-drupeaceous fruits, in the shape of its seed, in its ruminate albumen, and in its erect embryo: in these two last particulars it agrees with *Anonaceæ*. The dark green foliage and fragrant flowers make the members of this genus an ornament in the conservatory, where they flower freely in the autumn. *A. stellata* produces a fragrant wood. [W. C.]

**AMADOU.** A soft leathery substance, derived from *Polyporus fomentarius* and some other *Polypori*, and used for tinder, moxa, and other economical or medical purposes. It is prepared by cutting off carefully the cuticle and pores of the fungus, dividing it into convenient slices, heating them out, and steeping them in a solution of saltpetre. Occasionally, it is used to make coarse clothing, and then the latter process is omitted. The best Amadou is prepared in Germany, from *Polyporus fomentarius*, but *P. igniarius* and other species afford an inferior quality. The softer and more silky the substance of the fungus, the better the material. The fungus is generally collected from trunks of trees in the forests, where it is tolerably abundant; but attempts have also been made at cultivating it by collecting timber in proper situations, and watering it at proper intervals. The species occurs pretty generally in this country, but is not sufficiently frequent to make its collection a matter of interest. [M. J. B.]

Amadou, is sometimes called German Tinder in the shops. The wood of *Hernandia guianensis* is used in a similar way in South America. [T. M.]

**AMADOUVIER.** (Fr.) *Polyporus igniarius*.

**AMALAGA.** *Chavica officinarum*.

**AMANDE DE TERRE.** (Fr.) *Cyperus*

**AMANDIER.** *Amygdalus*. — A LA MAIN, or DES DAMES. *Amygdalus fragilis*. — DE GE'ORGIE. *Amygdalus nana*. — SATINE'. *Amygdalus orientalis*. — DU BOIS. *Hippocratea comosa*.

**AMANITA.** A sub-genus of *Agaricus*, distinguished by its gills producing white spores, and the whole plant being covered at first by a distinct universal wrapper, or volva. It contains some of the most excellent and poisonous of *Agarici*—amongst the former being the Orange and *A. vaginatus*; and among the latter the Fly Agaric and *A. virosus*. Some of the species have a distinct ring upon the stem; while others are wholly deficient in this ornament. The Fly Agaric (*A. muscarius*), with its vermilion pileus studded with white or yellow warts, and its stately stem, is the ornament of beech woods in most parts of the kingdom, and seldom fails to excite admiration, especially when illuminated by a strong gleam of light. Several species—and especially those of Sikkim, where they abound—are amongst the largest of the fleshy *Fungi*. [M. J. B.]

**AMANSIA.** A lovely genus of rose-spored *Algae*, mostly inhabiting the southern hemisphere, with a pinnate frond and generally involute tips. The frond is ribbed; the membrane formed of oblong six-sided cells, of equal length, arranged in transverse lines; the tetraspores are in marginal or superficial podshaped processes—generally in two rows; and the pyriform spores form a little fascicle at the base of the sub-globose capsules, which are perforated at the tip. Some species have almost exactly the habit of *Jungermannia*. [M. J. B.]

**AMARACUS.** (Fr.) *Origanum Dictamnus*.

**AMARANTH, GLOBE.** *Gomphrena globosa*.

**AMARANTHACEÆ.** (*Amaranthi*; *Polycnemæ*.) Under this name are included about 500 species of weeds, or, occasionally, showy annual plants (very seldom undershrubs), with inconspicuous apetalous flowers, in almost all cases of a scarious texture, and most commonly with a white colour—now and then pink, orange, or crimson. They are very nearly the same as *Chenopods*; and belong to Lindley's *Chenopodal* alliance. They occupy dry, stony, barren stations, or thickets upon the borders of woods, or even salt marshes; are much more frequent within the tropics than beyond them; and are unknown in the coldest regions of the world. Many of the species are used, with the addition of lemon-juice, as pot-herbs, on account of the wholesome mucilaginous qualities of the leaves. *Gomphrena officinalis* and *macrocephala* in Brazil, where they are called Para todo, Perpetua, and Raiz do Padre Salerma, are esteemed useful in all kinds of diseases, especially in cases of intermittent fever, colic, and diarrhoea, and against the bite of serpents.

**AMARANTHUS.** A genus of tropical annual plants, the type of a natural order, to which it gives its name—the *Amaranthada*. They are readily distinguished from the few other genera of the order by their

three-bracted coloured calyx of three or five pieces, and their one-seeded fruit, splitting irregularly round when ripe. The genus includes several handsome garden plants, the chief being the *A. caudatus*, popularly known as Love-lies-bleeding, and in France as *Queue de Renard* and *Discipline de Religieuses*, having long pendulous compound racemes of crimson flowers; the *A. hypochondriacus*, or Prince's Feather, with erect flower spikes and purplish foliage; the *A. speciosus*, or larger Prince's Feather, resembling the last, but differing by its more vigorous growth; and the *A. tricolor*, from China, an interesting species, more remarkable for the vivid colours of its foliage than for its flowers, which are insignificant. The last-named is much more tender than the other species; and, in the open air in this country, it is only in warm summers that its leaves assume the glowing tints to which the plant owes its specific name. In the gardens of the Southern United States, these hues are so richly developed as to have procured for it the popular appellation of Joseph's Coat. The plant known as Globe Amaranth belongs to another genus—*Gomphrena*. The name of this genus is often written *Amarantus*.

[W. T.]

AMARANTINE. (Fr.) *Gomphrena globosa*.

AMARANTOIDE. (Fr.) *Gomphrena coccinea*.

AMARELLE. (Fr.) *Cerasus avium*.

AMARINIER. (Fr.) *Salix vitellina*.

AMARYLLIDACEÆ (*Narciss*). A large natural order, consisting for the most part of bulbous plants, but occasionally forming a tall, cylindrical, woody stem, as in the genus *Agave*. They differ from Irids in having six introrse stamens, and from Niliaceous plants in their ovary being inferior. A few species of *Narcissus* and *Gala-* are found in the North of Europe and the same parallels. As we proceed south they increase: *Pancratium* appears on the shores of the Mediterranean; *Ornithoglossum* and *Pancratium* in the West and East Indies; *Hemerocallis* is found for the first time with some of the latter on the Gold Coast; *Hippeastrum* show themselves in countless numbers in Brazil, and across the whole continent of South America; and, finally, at the Cape of Good Hope, the maximum of the order is beheld in all the beauty of *Hemerocallis*, *Ornithoglossum*, *Clivia*, *Cyrtanthus*, and *Brussavigia*. A few are found in New Holland, the most remarkable of which is *Dorothyanthus*. Poisonous properties occur in the viscid juice of the bulbs of *Buxifera toxicaria* and *Hippeastrum*; those of *Lomatium vernum*, the Snowdrop and Daffodil, and other kinds of *Narcissus* are emetic. Nevertheless the *Agave*, or American aloe, as it is called, has an insipid sweet juice. Others are detergent, and a few yield a kind of arrow-root. Between 800 and 400 species are

AMARYLLIS. The type of the Amaryllidaceous family, and formerly made to include a large number of species. It is now, however, generally limited in extent, and confined to those which have the tube of the perianth short, narrow funnel shaped, and ribbed; the three petaline filaments inserted at the base of the segments; the three sepaline ones adnating to the mouth of the tube; the style declinate; the capsule obovate. They are handsome bulbous plants, with an autumnal flower-scape appearing before the leaves, which are humal. The scape supports a many-flowered umbel of large stalked flowers, the anthers of which are incumbent, attached in the middle. The typical species is *A. Belladonna*, which is separated by some as a distinct genus. This plant is a native of the Cape of Good Hope, and is of vigorous habit, producing flower-scapes one and a half foot high, and large, showy, funnel-shaped flowers of a pale delicate rose beautifully pencilled with red, in the month of September, the flowers being succeeded by the leaves, which are ligulate or strap-shaped. *A. Josephine*, and *A. grandiflora*, sometimes placed in *Brunsvigia*, are referred hither by Herbert. Most of the plants called *Amaryllis* in gardens, e.g. *A. equestris*, are now referred to *Hippeastrum*; others, as *A. formosissima* to *Sprekelia*, *A. lutea* to *Oporanthus*, and *A. purpurea* to *Vallota*. The *A. Belladonna* has been said to be employed for poisoning in the West Indies, but this statement appears to be a mistake, and probably refers to some other plant of the same order, the *Belladonna* being a Cape plant. The name *Belladonna* Lily was given to the flower in Italy from the charmingly blended red and white of the perianth, resembling the complexion of a beautiful woman.

[T. M.]

AMARYLLIS CANDELABRE, or GIL-RANDOLE. (Fr.) *Coburgia multiflora*. — SALTIMBANQUE. *Sprekelia Cybister*. — DE GUERNESEY. *Nerine sarniensis*. — DE VIRGINIE. *Zephyranthes Atamasco*. — JAUNE. *Oporanthus luteus*. — REINE DE BEAUTE. *Sprekelia formosissima*. — VE'NE'NEUSE. *Buxifera toxicaria*.

AMASONIA. A genus of the Vervain family (*Verbenaceæ*) nearly allied to *Clerodendron*, and chiefly differing from that genus in its habit. The species enumerated are six, all of them natives of southern tropical America and the greater part of them found in Brazil. They are perennial dwarf shrubs, with alternate or opposite leaves, and terminal racemed panicles of flowers, each little group of yellow flowers being supported by a large scarlet-coloured or beautifully variegated bract, which bears on its outer surface a number of pellucid glands. They are well-deserving of cultivation, but seldom met with.

[A. A. B.]

AMA-TSJA. Tea of Heaven; a kind of tea prepared in Japan from the leaves of *Hydrangea Thunbergii*.

**AMAUROPELTA.** A name given by Kunze to a West Indian Fern, supposed to have some affinity with the davallioid group, sometimes called *Saccoloma*. It is now referred to *Lastrea*. [T. M.]

**AMBASHI** or **AMBRASCHIA.** *Hernimaria Elaphroglon*, alias *Edenaea mirabilis*, the Fish-tree of the Nile.

**AMBATCHIA.** *Arum abyssinicum*.

**AMBER TREE.** *Anthospermum*.

**AMBERROA.** A genus of Composites, several of the plants composing which have long been cultivated under the more familiar name of *Centaurea*, from which genus the present one differs only in a few obscure and minute characters of the fruit and pappus. The two best-known species are the *A. odorata*, or Yellow Sweet Sultan, and the *A. moschata*, or Purple Sultan. Both are branching annuals, growing a foot or more high, with oblong pinnatifid foliage, and large terminal showy flower-heads. Those of the first are characterized by having the outer florets much longer than those of the centre, and the fruit is crowned with a short pappus of hairs. In the case of the latter species, *A. moschata*, the pappus is altogether wanting, and the florets of the circumference are scarcely longer than the central ones. The odour of this species is hardly suggestive of musk, as its name would imply, but is rather honey like. [W. T.]

**AMBYOCARPUM.** The generic name of a Persian weed of no beauty, belonging to the Composite family, and closely related to *Carpesium*, but differing in the strap-shaped and female ray florets being in a single row, as well as in the achenes—which are five, angular, and without pappus—being beakless. The plant is called *A. musoides* from its resemblance to our Fleabane (*Inula Pulegioides*). Its lance-shaped leaves are, however, longer and smooth, not downy. The yellow flower-heads are single at the ends of the twigs, and nearly half an inch across. [A. A. B.]

**AMBYOLEPIS.** A Texan genus of Composites, of which a single species, *A. scitorea*, is in cultivation, and possesses some interest from the pleasing fragrance of its flowers, which they retain for many years when dried. This fragrance, which the seeds of the plants possess in a high degree, is doubtless due to the presence of coumarin, the chemical principle to which the well-known tonka bean, and the common vernal grass, *Anthoxanthum odoratum*, also owe their agreeable scent. The species in question is a dwarf, erect, branching annual, with entire, ovate, lance-shaped, stem-clasping leaves, two to three inches long, the branches being terminated by a single flower-head one and a half inch in diameter, with a ray of broadly wedge-shaped florets, and a disk of tubular ones, both being of a uniform orange-yellow colour. The involucre consists of about ten ovate, lance-shaped, spreading bracts, the receptacle is naked

and conical, and the villous fruit is crowned by a pappus of five broad, blunt, transparent, colourless scales. [W. T.]

**AMBORA.** A genus of *Monimlaceae*, consisting of trees from Madagascar and Mauritius, with entire evergreen leaves, and monœcious flowers, generally in racemes, though sometimes solitary, rising from the trunk or lower parts of the branches. The male flowers are scattered among the more numerous females. The stamens are numerous, with short filaments and bilocular anthers. There are many one-celled ovaries, each containing a single ovule. The fruit consists of many one-seeded drupes, enclosed in the enlarged calyx, which gives it a baccate appearance. The bark and leaves exhale an aromatic odour. [W. C.]

**AMBORN.** (Fr.) *Cytisus Laburnum*.

**AMBOYNA WOOD.** The beautifully mottled wood of *Pterospermum indicum*.

**AMBRETTE JAUNE.** (Fr.) *Amberboa odorata*. — **MUSQUÉE.** *Liliciscus Abelmoschus*.

**AMBRINA.** A genus of plants belonging to the natural order *Chenopodiaceæ*. It comprises annual or perennial plants, with alternate, nearly sessile, cleft or sinuous leaves, covered, like the whole of the plants, with resinous spots. The flowers are clustered in heads, which are placed in the axils of the leaves, or in leafless or leafy terminal spikes. The genus is allied to *Chenopodium*, from which it differs in its obovate fruit, not depressed in the centre, and by the seeds being placed vertically in the seed vessel, not horizontally. From the genus *Bitum* it differs in the calyx, becoming of a pentagonal shape when it invests the fruit. All the species have an aromatic odour, and possess tonic and stimulant properties. *A. pinnatifida* is cultivated for the sake of its elegant and aromatic foliage. *A. ambrosioides*, or Mexican Tea, originally a native of North America, but long naturalised in the south of Europe, is used medicinally in the form of an infusion, having antispasmodic vermifuge and carminative properties. *A. anthelmintica* is common in the Southern States of America, where it is employed as a vermifuge. [M. T. M.]

**AMBROISE.** A name given in Jersey to *Teucrium Scrodonia*.

**AMBROISINE.** (Fr.) *Chenopodium ambrosioides*.

**AMBROSIA.** A genus of the Composite family (*Compositæ*), chiefly annual coarse-habited weeds, with opposite, or alternate lobed, or dissected leaves and the flower-heads in racemes or in bundles in the axils of the leaves. The sterile and fertile flowers occupy different heads on the same plant. The sterile involucre, somewhat top-shaped, composed of seven to twelve scales, united into a cup, and con-

containing five to twenty staminate flowers. The fertile ones top-shaped, closed, pointed, and usually with four to eight horns or tubercles near the top in one row, and containing a single flower composed of a pistil only. The species, of which there are about twelve, are pretty widely diffused, being found in India, tropical Africa, South Europe, and in North and South America, growing in fields and waste places. *A. artemisiifolia* is very plentiful on the plains of the Saskatchewan and Red River; while *A. tenuifolia* is said to cover thousands of miles of the Pampas, south of Buenos Ayres, giving them a black appearance like that of the Scotch moors. *A. trifida* is called the Great Rag-weed in America, and *A. artemisiifolia* the Roman Wormwood; indeed, all the species bear a great resemblance to the Wormwood (*Artemisia*). *A. maritima*, found in Italy and the Levant, is said to be tonic and resolutive; all its parts give out a sweet odour and have an aromatic taste, a little bitter, but agreeable. [A. A. B.]

**AMBROSINIA.** A genus of *Aroidæ*, containing a few species, natives of Sicily and Sardinia. They are small land plants, with tuberous, stoloniferous rhizomes, entire leaves, and a small spathe, inclosing a couple of scentless flowers, of which the uppermost has many monadelphous stamens perfectly destitute of a calyx, and a single unilocular ovary. They are referred by Endlicher to *Aroidæ*, but Lindley considers that the paucity of flowers in the spadix affords sufficient ground for establishing another order, which he calls *Pistaceæ*, and which includes *Lemna*, *Pistia*, and some other allied genera. [W. C.]

**AMELANCHIER**, the Savoy name of the Medlar, is given to a family of Pomaceous trees, of Europe and North America, allied both to *Mespilus* and *Cotoneaster*. In British gardens they are cultivated for their flowers, which are white, abundant, showy, and produced early in the season; for their fruit, which ripens in June; and for the deep red or rich yellow hue which their foliage assumes in autumn. The common Amelanchier, *A. vulgaris*, has long been cultivated in England, where it sometimes attains the height of fifteen or twenty feet. It bears abundance of flowers, and its fruit, though not highly palatable, is eatable. This is a native of Southern Europe, where it grows in rocky mountainous woods. The American species, *A. betropium*, or the Grape Pear, bears sparingly small fruit of a purplish colour and of an agreeable sweet taste, which ripens in June, before that of any other tree. *A. ovalis*, considered by some to be merely a variety of the preceding, abounds, according to Dr. Richardson, in the sandy plains of the Saskatchewan. Its wood is prized by the Orees for making arrows and pipe-stems, and is thence termed by the Canadian voyageurs *Bois de Pécha*. Its berries, about the size of a pea, are the latest fruit in the country, and are used by

the Orees both in a fresh and dried state. They form a pleasant addition to pemmican, and make puddings very little inferior to plum-pudding. [C. A. J.]

**AMELINGUE.** (Fr.) A kind of Olive.

**AMELLON.** (Fr.) A kind of Olive.

**AMELLUS.** A genus of the Composite family (*Compositæ*), containing twelve species, all of them natives of South Africa. They are herbs or shrubs, their lower leaves opposite, the upper alternate, oblong, entire or toothed, and hairy or canescent. Flower-stalks terminal, bearing a solitary head of flowers; the florets of the disc yellow, those of the ray blue. *A. Lychitis* is cultivated in gardens. The flowers of it, and most of the species, are a good deal like those of the *Michaelmas Daisy* (*Aster*), to which genus this is allied, differing chiefly in the opposite lower leaves, and in having the bristles of the pappus in a single series. [A. A. B.]

**AMENTACEÆ.** Under this name were once comprehended all apetalous unisexual plants, whose flowers grow in catkins, or aments. Modern botanists find it more convenient to distribute them through several different orders, the chief of which are *Salicaceæ*, *Corylaceæ*, *Betulaceæ*, *Casuarinaceæ*, *Altingiaceæ*, *Myricaceæ*, which see. A forest of these amentaceous plants as they grow in the island of Java, is shown in Plate IX.

**AMENTUM.** A catkin. A deciduous spike of unisexual apetalous flowers, such as appears in the spring on the hazel and willow.

**AMESIUM.** A name once proposed to be given to *Asplenium septentrionale* and some allied species. [T. M.]

**AMETHYSTEA.** An insignificant Siberian genus of Labiateæ, belonging to the *Ajuga* or bugle division of the order, and distinguished by the very short upper lip of its corolla, and the abortion of its upper pair of stamens. The only species, *A. carulea*, was formerly cultivated, but is now seldom met with, so many more deserving plants being available. It is a hardy annual, growing a foot or more high, with erect, square, branched stems; opposite, three-parted leaves; the segments oblong lance-shaped; and short terminal leafy racemes of very small pale-blue flowers, the corollas of which are scarcely longer than the calyx. As an ornamental plant, it is entirely worthless, but it possesses the merit of being slightly fragrant. [W. T.]

**AMHERSTIA.** A genus of the Pea family (*Laguminoæ*), named in honour of the Countess Amherst. *A. nobilis* is the only species. It grows near Martaban, in the Malayan peninsula, and attains a height of about forty feet. When in flower, it is said to be 'one of the most superb objects imaginable, unrivalled in India or in any other part of the world.'

The leaves are equally pinnate, large, and, when young, of a pale purple colour. 'The flowers are large, scentless, and of a bright vermilion colour, diversified with three yellow spots, and disposed in gigantic ovate pendulous bunches.' The tree is cultivated in some of the largest English gardens; but, requiring so much space, is seldom met with in collections. The Burmese name of the plant is *Thoca*, and handfuls of the flowers are offered before the images of Buddha. [A. A. B.]

**AMIANTHIUM.** The name of a genus of North American plants, belonging to the same family—*Melanthaceae*—as the *Colchicum* and *Veratrum*. The species have a widely-spreading petal-like perianth, without glands; six stamens attached beneath the ovary, with their anthers bursting outwardly; a capsule of three cells, which separate one from the other when ripe. One species, *A. muscatolicum*, contains a narcotic poison which is injurious to cattle that browse on its foliage. Its bulbs, pounded and mixed with honey, are used as a fly poison. [M. T. M.]

**AMICI.** (microscopical observer.) Four species are known, one from the vicinity of Loxa, another from the Cordilleras of Mexico (at an elevation of 5,000 to 8,000 feet), and two from Bolivia and Columbia. They are straggling shrubs, having alternate pinnate leaves, with few leaflets. Their flower stalks are axillary or terminal, having at their base two large, kidney-shaped, coloured bracts. Two of the segments of the calyx are large compared with the others, and roundish in form. The pods are compressed, and jointed. All the parts of the plant are covered with pellucid, glandular dots, somewhat like those of St. John's wort. *A. syzomeris*, the Mexican species, is sometimes to be found in gardens, and is well worth cultivation, especially as it flowers late in autumn, or during the early part of winter. It is generally treated as a greenhouse plant; but, in the South of England, if planted out of doors in the spring, it generally flowers well in the autumn. The flowers are large, and of a pale yellow colour—about the size of an everlasting pea. [A. A. B.]

**AMIDONNIER.** (Fr.) *Triticum dicoccum*, sometimes called *T. amyleum*.

**AMMANIA.** A genus of inconspicuous herbs, of the order *Lythraceae*, growing in wet places in the warmer regions of the globe; mostly glabrous annuals, with square stems, opposite entire leaves, and small axillary, nearly sessile flowers, often without petals. Several species have been introduced, but are more curious than beautiful. *A. vesicatoria* has acrid leaves, which, when bruised, are used by the native practitioners of India to raise blisters. [J. T. S.]

**AMMI.** A small genus of Umbelliferous

plants, with the habit of the carrot (*Daucus*), spindle-shaped roots, and many-parted leaves; it is remarkable for the large size of the outer petals of the umbel. As the name denotes (from the Greek *amos*, sand), they affect sandy ground, but will thrive if sown in the common soil of the garden border. Common Bishop-weed, *A. majus*, is a native of the south and middle of Europe, Egypt, and the Levant, where it attains the height of three or four feet. Tooth-pick Bishop-weed, *A. Visnaga*, is so called on account of the use made in Spain of the rays or stalks of the main umbel. These, after flowering, shrink, and become so hard that they form convenient tooth-picks. When they have fulfilled this purpose, they are chewed, and are supposed to be of service in cleaning and fastening the gums; however this may be, the leaves have a pleasant aromatic flavour in the mouth. [C. A. J.]

**AMMOBIUM.** In a structural point of view, this genus is allied to *Gnaphalium* and *Antennaria*, from which it differs but slightly, except in habit. Two species are

row foot-stalk, those of the stem and branches very small, and prolonged downwards in a narrow, wing-like form. The flower heads, which are of the dry everlasting character so common to plants of the Australian continent, are nearly an inch across, with a disk of tubular florets; a receptacle set with oblong, pointed, toothed, chaffy scales; an involucre of imbricated leaflets, the inner series of which have membranous margins, and a four-angled, elongated fruit, furnished at the apex with four teeth, the two larger of which are terminated by a bristle. The plant remains some time in flower, and is not without a certain degree of interest; though, as an ornamental plant, it is almost superseded by the more recent species of *Helichrysum*, *Rhodanthe*, and *Acroclitum* from the same continent. [W. T.]

**AMMOCHARIS.** A genus of *Amaryllidaceae*, in which the tube of the six-parted perianth is cylindrical, enlarged, the sepaline divisions not imbricating thereon; the filaments of the stamens are adjusted almost equally at the base of the limb; the anthers are short, affixed in the middle; and the capsule is turbinate, three-celled. The leaves are vernal, and not sheathing. The genus is intermediate between *Crinum* and *Buphonia*, differing from the first in its anthers, its filaments inserted just within instead of without the tube, its shorter limb and wider-mouthed tube, and its leaves not sheathing; and from the last, by the wider mouth of the tube of the perianth, the insertion of the filaments within the tube, and the more numerous ovules. The two species, sometimes referred to *Brunsvigia*, are South African. *A. falcata* has ligulate glaucous leaves, and

a many-flowered umbel of greenish-white flowers, which afterwards become pinkish and finally rose-colour. [T. M.]

**AMMONIACUM.** A drug said to be obtained from *Dorema ammoniacum*, and also from *Ferula tingitana*.

**AMMOPHILA.** A genus of Grasses of the tribe *Arundineæ*, inhabiting the sandy sea-shores of the coasts of Europe and North America, and extensively cultivated in many places, as in the eastern counties of England and in Holland, for preserving the sand-banks which prevent the inroads of the sea. In the northern parts of England, it is used for making table mats and basket work. It is the widely-creeping and matted rhizomes which serve to bind together the sand-banks on which it grows. The stems grow two or three feet high, and bear long, narrow, rigid involute leaves and a spiked cylindrical panicle, with laterally compressed spikelets. The glumes are nearly equal, and lance-shaped, stiff and chaffy. The flowering glumes, or outer pales, are the shorter, with a tuft of hairs outside, but the inner pales nearly equal them in length. The genus is nearly related to *Calamagrostis*, from which the inflorescence, the stiff glumes, and the absence of an awn to the flowering glume, serve to distinguish it. The only species, *A. arundinacea*, or *Psamma arenaria*, is variously called Maram, Marrum, Sea-reed, or Sea-weed. [T. M.]

**AMNIOS.** The fluid that is produced within the sac which receives the embryo-rudiment and engenders it.

**AMOMUM.** A genus of aromatic herbs, belonging to the Ginger family, *Zingiberaceæ*. The root-stocks are jointed, creeping; the leaves placed in two rows, sheathing at the base, lance-shaped, and undivided at the margin. The flowers, in a spike or cluster, are provided with bracts, and but little raised above the ground; there is but one stamen, whose filament is prolonged beyond the two-lobed anther, so as to form a more or less lobed crest; the capsule is three-celled, and opens, when ripe, by three pieces, so as to liberate the numerous small seeds. These plants are natives of India, the islands of the Indian Archipelago, etc. Their seeds are aromatic and stimulant, and form, with other seeds of similar plants, what are known as Cardamoms, of which there are many kinds.

*Attare*, *Malaguetta* Pepper, or Grains of Paradise, are the seeds of one, perhaps two, species of this genus, *A. Grana Paradisi* and *A. Meleguetta*. They are imported from Guinea, and have a very warm, slightly camphor-like taste. These seeds are made use of illegally to give a fictitious strength to spirits and beer, but they are not particularly injurious; although, from the very heavy penalty inflicted on brewers who have them in their possession, and on druggists who sell them to brewers (300l.

and 500l. respectively), it would seem as if such an opinion were entertained.

The large round China Cardamoms are supposed to be produced by *A. globosum*, the hairy round China sort by *A. villosum*, Java Cardamoms by *A. maximum*; but the botanical history of the plants producing

*Amomum Grana Paradisi.*

the various kinds of Cardamoms, Grains of Paradise, etc., is involved in much confusion and obscurity. Several species of the genus are in cultivation as ornamental stove plants. [M. T. M.]

**AMOMUM.** (Fr.) *Solanum pseudo-Capsicum*.

**AMOREUXIA.** A genus of *Flacourtiaceæ* containing two species from Mexico and New Granada. They are herbaceous plants, with the habit of *Malva*. The root is a large ligneous tuber. The leaves are alternate, on long petioles, and digitato-partite. The large flowers are in terminal racemes, and consist of five oblong persistent sepals, and five caducous obovate petals. The stamens are indefinite and arranged in two bundles, the one having very much longer and stouter filaments than the other. The ovary is ovate and trilobular, with many ovules attached to a central placenta. M. Planchon has joined this genus with *Cochlospermum* to form a small order *Cochlospermææ*, which he places near *Malvaceæ* and *Egyphyllitaceæ*; but both it and *Cochlospermum* are united by Benth and Hooker with *Bixa*, to form the tribe *Bixææ* in *Flacourtiaceæ*. [W. C.]

**AMORPHA.** The flowers which belong to the natural order *Leguminosæ*, though composed of petals unequal in size and irregular in form, have, for the most part, these organs symmetrically arranged, after the type of the pea and bean. In the pre-

sent genus, however, the two pairs of petals, termed severally the wings and keel, are absent, the only representative of petals being the standard or vexillum, and hence its name *Amorpha*, 'deformed.' All the plants of the genus are deciduous shrubs, natives of North America. The leaves are pinnate with a terminal leaflet, covered with pellucid dots; and the flowers, of a blue-violet colour, are disposed in long spiked clusters, grouped at the tops of the branches. All the species are ornamental. The foliage is graceful; and the flowers, though individually small, are attractive from their numbers and colour, which is violet spangled with the golden anthers. As they only attain the height of a few feet, they are well adapted for small shrubberies, or the front of large ones, and thrive well in common garden soil. *A. fruticosa*, the commonest species in European gardens, was introduced to Britain in 1724 by Mark Catesby, who states that the inhabitants of Carolina at one time made a coarse sort of indigo from the young shoots. Hence it is sometimes called Bastard Indigo. [C. A. J.]

**AMORPHOPHALLUS.** A name given to a genus of plants of the araceous family, and used to indicate the exceedingly curious appearance of the plants, which are perennial, with tuberous rootstocks flattened on the upper surface. The leaves and spadices are solitary, invested below with imbricated scales. The spathe is spreading so as to fully expose the thick fleshy spadix, which is dilated and fungus-like at the upper extremity. The male flowers are placed above the females; their anthers are sessile and open by pores; the ovary has either two, three, or four cells, with erect ovules. These plants were formerly included in the genus *Arum*, from which they are distinguished by their spreading not convolute spathes; by their anthers opening by pores, not by longitudinal slits; by the numerous cells to the ovary; and by the solitary erect ovule, those of *Arum* being horizontal. They are natives of India and other parts of tropical Asia, where they are cultivated for the sake of the abundance of starch which is found in the rootstock. The presence of this starch, and especially the mode of preparation, deprives the roots of their otherwise acrid caustic properties. Dr. Wight says of *A. campanulatus*, that when in flower the fetor it exhales is most overpowering, and so perfectly resembles that of carrion, as to 'induce flies to cover the club of the spadix with their eggs.' [M. T. M.]

**AMORPHOUS.** Having no definite form.

**AMOURETTE.** (Fr.) *Briza media*; also *Saxifraga umbrosa*.

**AMPELOPSIS.** A North American genus of *Vitaceae*, distinguished from *Vitis* and *Cissus*, to which it is closely allied, by the absence of the disk or expansion of the receptacle in a ring round the base of the ovary. *A. hederacea*, the Virginian Creeper,

or American Ivy, is a shrubby climber, often planted in this country to cover walls, for which, from the rapidity of its growth, it is well adapted; the leaves, which have five large elliptical leaflets, turn red before they fall in autumn, when the plant presents a very beautiful appearance. The flowers are small and yellowish-green, in a many-flowered panicle. The tendrils are curious, adhering to supporting bodies by small sucker-like expansions which are formed at the apex of each of their divisions. This is particularly noticeable in the *A. tricuspidata*, cultivated under the name of *A. Vedoitt*. [J. T. S.]

**AMPELOPTERIS.** A name proposed by Kunze for a few Indian Ferns now referred to *Goniopteris*. [T. M.]

**AMPHIREPHIS.** A Brazilian genus of Composites, of which *A. intermedia* is occasionally found in cultivation. It is a branched spreading annual, growing a foot or more high, with ovate, serrated foliage, and terminal flower-heads, an inch across, composed wholly of tubular florets of a purple colour, and surrounded by a double series of leafy bracts or scales. [W. T.]

**AMPHIBLESTRA.** A genus of polypodiaceous ferns belonging to *Pteridea*, and distinguished in this group by having the veins of the fronds compoundly reticulated, with free included veinlets, or little veins within the meshes or areoles. It is a coarse-looking fern of South America, with much the aspect of *Aspidium trifoliatum*, but having the pteroid linear marginal indusiate fructification. [T. M.]

**AMPHIBOLIS.** A genus of *Zosteraceae*, formed to include a plant found in the Pacific Ocean and on the coast of New Holland; and considered by Endlicher and Kunth to belong to *Cymodocea*. The only species, *A. zosterifolia*, has branched annulated stems, and approximate alternate, linear, truncate, and bidentate leaves, with short truncated stipules. [J. T. S.]

**AMPHICOME.** A genus of the bignonia family (*Dignoniaceae*). Two species are known, and both of them natives of the temperate regions of North Western India. They are perennial herbs, with alternate, unequally pinnate leaves, and toothed leaflets. The flowers are pink, tubular, and arranged in axillary or terminal racemes. The fruits are about the length and thickness of a crowquill, and their seeds are provided with a tuft of hairs at each end, this circumstance giving rise to the name of the genus—*amphi*, on both sides, and *koma*, a head of hairs. They are both in cultivation. *A. Emodi* is a remarkably handsome plant, and well deserves a place in choice collections; it is about one foot high, and the flowers, which are large for the plant, stand erect when expanded. *A. arguta* is about the same size, but it has smaller drooping flowers. [A. A. B.]

**AMPHICOSMIA.** A genus of cyatheaceous ferns, belonging to the section

*Cyathea*, in which group it is distinguished by having beneath the sorus, on the hinder side, a half-cup-shaped indusium, and by having the veins of the fronds free. The species are sometimes referred to *Alsophila*, to *Hemitelia*, or to *Cyathea*. Several species, chiefly South American, agreeing in having the half-cup indusium and free veins, are referred to the genus in *Index Filicum*; but there is also one species from the Cape of Good Hope, two from India, and one from New Holland. The typical species is *A. capensis*, found both at the Cape and in Java, a tree-fern growing twelve to fourteen feet high, and of which, according to Dr. Harvey, there is a noble forest in the woods on the east side of Table Mountain. The fronds of this are three times pinnate, and unarmed. [T. M.]

**AMPHIDESMIUM.** A genus of cyathaceous Ferns, closely related to *Alsophila*. They are distinguished—having oblique-tinged spore-cases and naked sori with elevated receptacles—by producing two or three sori in different positions on the same vein, the veins in *Alsophila* bearing one only. They are also different in aspect, having bold pinnate fronds, which give them a noble appearance. The species *A. blechnoides* is found in various parts of South America and in the West Indies. [T. M.]

**AMPHIGASTRIA.** The so-called stipules of Scale-mosses, or *Jungernannias*.

**AMPHIGENÆ.** A name applied by Brongniart to Thallogens, implying that they are developed in every direction, without any distinct axis and appendages; and not especially at the apex, like ferns and mosses, to which he has applied the name of Acrogens, and which, in contradiction to Thallogens, are furnished with both axis and appendages. [M. J. B.]

**AMPHILOCHIA.** A genus of *Yockystaceæ*, containing four species from Brazil. They are trees, with opposite petiolate and entire leaves, and glands at the base of the petioles. The flowers are in terminal racemes. The calyx consists of five coloured sepals, combined at the base, the upper being much the largest and spurred. The corolla has only a single petal, inserted in the base of the calyx between the two front sepals. There are two stamens, one on either side of the petal. The ovary is three-celled, with few ovules. [W. C.]

**AMPHISARCA.** A many-seeded many-celled superior indehiscent fruit, woody on the outside, pulpy within.

**AMPHISTENON.** a genus of *Dioscoreaceæ*, formed by Grisebach by the subdivision of *Dioscorea* into many new genera. The section to which this name has been given, is separated from the others by having six short fertile stamens, which are inserted on the apex of the calyx tube. It contains eleven species of tropical, chiefly Brazilian, herbaceous plants. [W. C.]

**AMPHITROPAL.** When an ovule is attached by its middle, so that the two ends are equidistant from the point of insertion.

**AMPLEXICAUL.** Embracing; as when a leaf clasps a stem with its base.

**AMPOULLEAU.** (Fr.) A kind of olive.

**AMPULLA.** The metamorphosed flask-like leaves found on certain aquatics such as *Utricularia*; not different from *Ascidium*.

**AMSINCKIA.** A genus of the Boraginæ family, numbering seven species, found in Oregon, California, Mexico, and Chili. They are annual erect herbs, of little beauty; all their parts more or less clothed with rusty hairs. The stems, six inches to one and a half feet high, are furnished with alternate and entire linear, lance-shaped, or ovate leaves, one to five inches long, and terminate in one or more one-sided racemes of yellow funnel-shaped flowers, with a flat border of five rounded lobes. In the largest flowered species (*A. spectabilis*, from California), the corolla tube is three-quarters of an inch in length. The fruit consists of four triangular one-seeded nuts, their dorsal face smooth, or covered with warty excrescences. The seeds are remarkable, from having their cotyledons deeply biparted. [A. A. B.]

**AMSONIA.** A genus of *Apocynaceæ*, consisting of five species, natives of North America. They are perennial herbaceous plants, with alternate leaves, and pale blue flowers, in terminal paniced cymes. The calyx is small and five-parted; the corolla has the same number of long linear lobes; its narrow funnel-shaped tube is bearded inside, especially at the throat. There are five included stamens, with obtuse anthers, which are longer than the filaments; two ovaries, a single style, and a rounded stigma, surrounded with a cup-shaped membrane. The two pods are long and slender, with many naked cylindrical seeds, in a single row. [W. C.]

**AMYGDALOPSIS.** A supposed genus of *Drupaceæ* plants formed on the Japanese *Prunus triloba*. Its distinctive character is having several carpels in each flower instead of one; probably a mere malformation, such as occurs in the peach and plum themselves.

**AMYGDALUS.** The name applied to the genus to which the Almond, the Peach, and the Nectarine belong. It is placed by botanists in the *Drupaceæ* subdivision of the *Rosæ* family, and is especially known by the stone of the fruit, which encloses the kernel or seed, being coarsely furrowed or wrinkled, and by the leaves being folded in halves, not rolled round when young.

The Almond-tree (*A. communis*) appears to have been originally a native of Barbary and Morocco; but by long cultivation it has become distributed over almost the whole of the warmer temperate zones of

the old world. It is a small tree, with oblong lance-shaped leaves, slightly saw-toothed at the margin. The flowers, which appear in spring, before the leaves, are solitary and of a beautiful pink colour. The fruit is a drupe, which is somewhat egg-shaped, downy externally; its middle portion tough and somewhat fibrous; its inner portion forming the hard wrinkled stone enclosing the seed within it. Many varieties of the Almond are cultivated, differing in the nature of their fruits; but the two principal are the Sweet and the Bitter Almond. The Bitter Almond has larger flowers than the sweet variety, and they are of a white colour. The styles are not longer than the stamens, and the seeds are bitter. The seeds of the Sweet Almond are much esteemed at the dessert table, in spite of their indigestibility. The bitter almonds, though occasionally used for flavouring purposes, should be employed in small quantities, as they contain a poisonous principle which is similar in its effects to prussic acid. The essential oil of almonds, which is much used as a flavouring ingredient by cooks and confectioners, is a most virulent poison: it contains prussic acid, and should therefore be employed with great care and in a diluted form, as in what is called in shops Essence of Almonds. It is curious that this oil does not exist naturally in the almond, but is formed by the chemical agency of water on some of its constituents.

*A. persica* is the botanical name given to the Peach, which is sometimes included in a separate genus (*Persica*), but it only differs from the almond in having a fleshy, not leathery, drupe. Instances have been cited of almonds having fleshy drupes, and thus assuming the character of the Peach. Three principal varieties of the Peach exist—clingstones, melters or freestones, and nectarines. The latter only differ from the peach in having smooth, not downy fruits; but both peaches and nectarines are occasionally met with on the same bough. The leaves of the Peach and Nectarine contain a small quantity of prussic acid, and have the taste and odour of bitter almonds. The fruits, taken in moderation, are as wholesome as they are delicious; but the kernels and blossoms contain prussic acid. The Peach is very extensively cultivated in America, but little attention is paid to the culture: the fruits are used in the manufacture of peach brandy, and for feeding hogs! (M. T. M.)

The common Almond-tree grows to the height of about twenty feet. The leaves closely resemble those of the Peach (*A. Persica*), but the flowers are larger than those of that species. Its fruits, which are the Almonds of commerce, are well known. They seldom attain maturity in this country, in which, however, the tree is frequently to be seen, on account of its showy blossoms, which appear in great abundance very early in spring, when the season is not unusually cold; they often appear in February, and, in the mild winter of 1834, a standard almond-tree in

the neighbourhood of London was in full flower in the end of January. De Candolle is of opinion that the Almond is a native of Persia, Asia Minor, Syria, and even Algeria. It is found growing spontaneously in many other countries, to which, however, it is not supposed to be indigenous, the plants met with having probably been derived from others introduced for the purpose of cultivation. In Palestine, it appears to have been cultivated from the earliest ages; for we find it enumerated among the best fruits of Canaan which were sent into Egypt as a present for Joseph, upwards of 3,500 years ago. The fruit of the Almond is of an ovate, somewhat curved, tapering form. It consists of a husk, which dries up and splits at maturity, exposing the stone, within which is the kernel, the only edible portion. There is a variety with bitter kernels, from which, like the sweet, oil can be extracted, but which are otherwise unfit for use, as they contain prussic acid in notable quantity. There are several varieties of the sweet-kernelled; some with hard, and others with comparatively tender, shells or stones. The most esteemed is the large thin-shelled, or Jordan Almond.

The Peach (*A. persica*) differs essentially from the Almond in the nature of the covering of the stone, which, instead of a dry husk, is fleshy, succulent, and delicious, when the fruit is ripened under favourable circumstances. The species comprises the Peach and Nectarine, the skin of the former being downy, and that of the latter quite smooth. They were supposed to be natives of Persia, and, on their introduction into the South of Europe, were called the *Malus persica*, or Persian apple. Professor De Candolle is, however, of opinion that China is the native country of the Peach. His reasons are, that if it had originally existed in Persia or Armenia, the knowledge and culture of so delicious a fruit would have spread sooner into Asia Minor and Greece. The expedition of Alexander is probably what made it known to Theophrastus, B.C. 322, who speaks of it as a Persian fruit. It has no name in Sanscrit; nevertheless, the people speaking that language came into India from the north-west, the country generally assigned to the species. Admitting this to be its country, how can it be explained that neither the early Greeks, nor the Hebrews, nor the people who speak Sanscrit,—and who have all sprung from the upper region of the Euphrates, or from parts communicating with it,—had grown the Peach-tree? On the contrary, it is very possible that the stones of a fruit tree cultivated from all antiquity in China, may have been carried across the mountains from the centre of Asia into Oshmere, or Bokhara and Persia; for the Chinese had discovered this road at a very remote period. This importation must have been made between the time of the Sanscrit emigration and the intercourse of the Persians with the Greeks. The cultivation of the Peach-tree, once established at this point, would easily

extend on one side towards the west, and on the other, by Cabul, towards the North of India. In support of the supposition of a Chinese origin, it may be added that the Peach-tree was introduced from China into Cochinchina, and that the Japanese call it by the Chinese name, *Tao*. In the Japanese encyclopædia it is stated to be a tree from western countries, which applies to China with regard to Japan, or rather to the interior of China relatively to its eastern coast: the statement having been taken from a Chinese author. The Peach is mentioned in the books of Confucius, 5th century before the Christian era; and the antiquity of the knowledge of the fruit in China is further proved by the representations of it in sculpture and on porcelain. The above are some of the arguments adduced by De Candolle against the commonly-received opinion that the Peach originated in Persia: for the full investigation of the subject, we must refer the reader to his *Géographie Botanique*, according to which excellent authority the conclusion is that China is the native country of this esteemed fruit. That it is there cultivated extensively, and to great perfection, is certain. The Flat Peach of China was introduced into this country more than thirty years ago. It is figured in the *Transactions of the Horticultural Society* (iv. 512, t. 19); and, more recently, a very large variety was brought from Shanghai by Mr. Fortune, which has the usual form exhibited by those cultivated in Europe.

In the South of France, and in other Continental countries possessing a similar climate, Peach-trees ripen their fruit very well as standards in the open air; but at Paris they require a wall; and, with this assistance, they also succeed very well in the southern parts of England, but in the northern the aid of fire-heat, and the protection of glass, are necessary. In America, the Peach grows almost without any care—extensive orchards, containing from 10,000 to 20,000 trees, being reared from the stones. At first the trees there make rapid and healthy growth, and in a few years bear in great abundance; but they soon decay, their leaves becoming tinged with yellow, even in summer, when they should be green. This is owing to their being grown on their own roots; for when that is the case in this country, the trees present a similar appearance. They require, therefore, to be budded on the plum or on the almond. Some doubts have been entertained as to whether the Peach is not the same species as the Almond. They appear, however, to maintain their respective characters sufficiently distinct, unless artificially or by accident they are crossed with each other. The possibility of this being effected was successfully tried by Mr. Knight; and the circumstance of their crossing readily proves their close affinity. He fertilised an almond blossom with pollen from a Peach blossom. An almond was the result; but from its kernel he raised a tree which bore peaches of fair

size and round form, with succulent melting flesh, of tolerably good quality, better, indeed, than some seedlings of the Peach itself.

The varieties of Peaches and Nectarines are very numerous, and would be difficult to distinguish, were it not for a classification formed from certain characters afforded by the fruit, leaves, and flowers. In some varieties the fruit has firm flesh, adhering to the stone; such are termed clingstones. Others have melting flesh, parting readily from the stone; these are called melters or freestones. The leaves are either glandless, or are furnished with globose, or with reniform glands at their bases. And in some the flowers are large, in others small. Formerly the Peaches and Nectarines, known in Europe, had all bitter kernels; but sweet-kernelled varieties have of late years been introduced from Syria. The following are some of the best varieties of Peaches: Noblesse, Royal George, Acton Scot, Grosse Mignonne, Bellegarde, Late Admirable, and Walburton Admirable. Of Nectarines, the *Violetto Hâtive*, *Pitmaston Orange*, *Downton*, *Elruge*, *Impératrice*, and *Balgowan* are amongst the most esteemed sorts. [R.T.]

**AMYLACEOUS GRANULES.** Grains of starch.

**AMYLIDÆ.** Cells in algae, secreting starch.

**AMYLOUM.** Starch; that organised granular matter of plants which iodine stains violet or blue.

**AMYLOID.** A substance analogous to starch, but becoming yellow in water after having been coloured blue by iodine.

**AMYRIDACEÆ.** (*Terebintaceæ*, *Bursaceæ*, *Amyridæ*.) With the appearance of oranges, and sometimes with the dotted leaves of that order, these plants differ in their fruit, forming a shell whose husk eventually splits into valve-like segments. In general, moreover, the petals have a valvate aestivation. The genera collected under this name are by no means perfectly known, and demand a scrupulous revision. The tropics of India, Africa, and America exclusively produce the species. Their resinous juice is of great importance, forming an ingredient in frankincense and other preparations demanding a fragrant combustible matter. See *AMYRIS*, *BURSERA*, *BOSWELLIA*, *BALSANODENDRON*, *LOICA*, and *CANARIUM*.

**AMYRIS.** A genus of trees belonging to the order *Amyridaceæ*, known by their unequally pinnate leaves, and by their solitary ovary, which contains two pendulous ovules. The plants are natives of tropical America and India, and are remarkable for yielding resinous products. It is supposed that the resin called *Klemi* is produced from some species of *Amyris*, such as *A. hexandra* and *A. Plumieri*, though there is much doubt, not only as to the plant or plants producing the drug, but

even as to whence it is imported. Indian Bdellium, or False Myrrh, is obtained from *A. commiphora*; it is a gum resin, possessing properties somewhat similar to those of the Myrrh, but is not so highly valued. *A. balsamifera* yields some descriptions of the wood which is called Lignum Rhodium. *A. toxifera* is poisonous. See BAL-SAMODENDRON. [M. T. M.]

**ANABAINA.** A genus of green-spored *Alga*, the species of which consist of neck-lance-shaped threads, of which some of the articulations are much larger than the rest. They either form a shapeless scum on the surface of pools, or roundish patches on the bare soil. They never develop a distinct solid frond like that of *Nostoc*. One of the species, *A. licheniformis*, is extremely common in gardens where the ground has been much trodden, as amongst raspberry bushes. The threads are a pretty object under the microscope, the large articulations being reproductive. One or two closely allied *Alga*, as, for example, *Aphanizomenon*, are remarkable for being suspended in the water in which they grow, and giving to it a green tint. [M. J. B.]

**ANABASIS.** A genus of *Salsolaceæ*, consisting of trees and shrubs, natives of Central and Eastern Asia, and of the eastern shores of the Mediterranean. They are jointed plants, generally aphyllous, or with leaves small and opposite. The flowers are sessile and single, or in a glomerulus, hermaphrodite, and furnished with two bracts. There are five sepals, and the same number of stamens inserted in the receptacle; between these and united to their bases are five minute scales or staminodes. The ovary is unilocular and uniovulate, and the style double and divaricate. There are seventeen species. [W. C.]

**ANACAMPSEROS.** A genus of under-shrubs from the Cape of Good Hope, referred to the order *Portulacaceæ*. They are succulent plants with crowded, imbricated, sessile, ovate-trigonal terete or subglobose leaves with stipules cut into five segments, often hair-like. Flowers large, white, rose, purple, or yellow, with twelve to twenty stamens; peduncles in some species very short, in others elongated, simple or branched. Several species are cultivated in greenhouses. [J. T. S.]

**ANACAMPTIS.** A genus of Orchids, established by A. Richard for the *Orchis pyramidalis*, which differs from the rest of the species by two small plates or appendages at the base of the labellum. A South European species in which these two plates are united into one horse-shoe-shaped appendage has since been added, and some botanists unite both species with *Gymnadenia* or with *Aceras*, but in a more natural arrangement they would be retained in *Orchis*. The *Anacamptis* (or *Orchis*) *pyramidalis* is not uncommon in central and southern Europe, extending eastward to the Caucasus.

**ANACARDIACEÆ** (*Terebinthaceæ*, Cas-

*subiacæ*, *Spondiaceæ*, *Anacardæ*, *Terebinthæ*). When trees or bushes have a resinous, milky, often caustic juice, dotless leaves, and small inconspicuous flowers, with an ovary containing a single ovule suspended at the end of an erect cord, it is pretty certain that they belong to this order, of which more than 400 species are described, inhabiting the tropics both north and south of the equator, but not known to occur in Australia. *Pistacia*, and some kinds of *Rhus*, inhabit temperate latitudes. Among the products of the order are the Mango fruit, and that called in the West Indies the Hog Plum; the nuts named Pistachios and Cashews, the Black Varnish of Burmah and elsewhere, Mastich, Fustic, &c. These varnishes are extremely acrid, and produce dangerous consequences to persons who use them incautiously. See MELANORRHŒA, MANGIFERA, SPONDIAS, RHUS, ANACARDIUM, SCHINUS, &c.

**ANACARDIUM.** A genus of woody plants, from which the family to which they belong derives its systematic name, *Anacardiaceæ*. The plants of this group are chiefly remarkable for their kidney-shaped fruit, which is placed on the end of the thickened fleshy pear-like receptacle. *A. occidentale*, a plant cultivated in the West Indies and other tropical countries, produces the fruits known as Cashew Nuts. It is a large tree, somewhat like a walnut-tree in appearance, but with oval, blunt,

*anacardium occidentale.*

alternate leaves; the fragrant rose-coloured flowers are borne in panicles. The stem furnishes a milky juice, which, as it dries, becomes black and hard, and is used as a varnish. A gum is also secreted by this plant, having qualities like those of gum

arable. It is imported into this country from S. America, under the name of Cadjil gum, and is used in S. America by bookbinders, who wash their books with it, to keep away moths and ants. The thickened receptacle has an agreeable acid flavour, with some degree of astringency; the fruit at its extremity is kidney-shaped, of an ash colour; the shell of the fruit consists of three layers, the outer and inner of which are hard and dry, but the intermediate layer contains a quantity of black, extremely acrid, caustic oil, which gives rise to severe excoriation of the lips and tongue in those who attempt to crack the nut with their teeth. This oil is sometimes applied to the floors of houses in India, to protect them from the attacks of white ants. The acrid matter is destroyed by heat, hence the kernels are roasted before being eaten, and then become wholesome and agreeable. The process of roasting has to be carefully conducted, the acridity of the fumes being so great as to produce severe inflammation in the face of persons approaching too near. [M. T. M.]

**ANACHARIS.** A submerged aquatic, belonging to the natural order *Hydrocharidaceae*, having long, much-branched stems, small pellucid leaves, which are usually inserted in whorls of three, or less frequently four, and inconspicuous flowers: an American plant, which made its appearance in several remote parts of Britain almost simultaneously about the middle of the nineteenth century. How it was intro-

*Anacharis Alismastrum.*

duced is unknown, and it is equally a mystery by what means it traversed the wide tracts of country which separate the various stations in which it first appeared; for, as it is dioecious, and pistilliferous plants alone have found their way to this country, it perfects no seeds. It easily propagates

itself from a small portion either of stalk or root, and is of wonderfully rapid growth; hence it has in many instances destroyed the beauty of ornamental pieces of water, impaired navigation in not a few inland canals, and interferes with the working of water-mills, by choking the outlets of reservoirs, especially towards the close of summer, when its debris are often brought down by the current in large quantities. Great efforts have been made to eradicate it in various places, but with imperfect success. It is greedily eaten by swans and some other water-birds; but even this service is not without its disadvantages, since portions of the stem, torn off but not consumed by these seeming allies, are carried away by the current, and transplanted elsewhere. In some places it is said to have almost disappeared, from having exhausted of its specific nutriment the soil in which it was rooted; but whether the ground will not, after a certain lapse of time, recover its productivity, and bear a fresh crop of *Anacharis Alismastrum*, remains to be seen. See Mr. Babington's remarks in *Journal of Botany British and Foreign*, new series, i. 97. [C. A. J.]

**ANACHASTE sanguinea** is a terrestrial Orchid, found at the sources of the Amazon river by Warzewicz, a Polish traveller. It has the habit of *Epidendrum maculatum*, with rich blood red or rose-coloured flowers, having somewhat the form of a *Composita*, without the spur. Plants were introduced by Mr. Skinner in 1853. The genus is nearly related to *Cochlidium*.

**ANACYCLUS.** A genus of the Composite family (*Compositae*), comprising eight species, which are found chiefly on the coasts of countries bordering on the Mediterranean sea. They are herbs with alternate, pinnati-lobed, much-cut leaves, and terminal solitary flower-heads; the ray florets white. In appearance they much resemble *Chamomiles* (*Anthemis*), and are chiefly distinguished from them by their achenes being bordered with a membranous wing. *A. Pyrethrum* grows in Barbary, Arabia, and Syria, and is cultivated in many places for the sake of its roots, which are used in medicine, and are called Pellitory of Spain. They are imported by the French from Africa, in pieces about the size of the finger. These, when fresh, if applied to the skin, cause a singularly cold sensation, immediately followed by heat. It is very pungent, and causes the saliva to flow freely. Sometimes it is given in tooth-ache, but is seldom taken inwardly. 'When chewed, it causes a pricking sensation in the lips and tongue, and a glowing heat.' [A. A. B.]

**ANADENIA.** The name given to a number of plants belonging to the large family of *Proteaceae*, but which are now generally included in the genus *Grevillea*. They are shrubs chiefly of West Australia, with variously cut and lobed leaves. [A. A. B.]

**ANADYOMENE.** A genus of calcareous green-spored *Algae*, consisting of branched or dichotomous articulated threads, which are laterally confluent with each other, so as to form a more or less fan-shaped membrane. They are most beautiful objects under a low power of the microscope, and might suggest elegant designs for the silversmith. The species, which are few in number, occur in the warmer seas, and consequently we have none upon our own coast. Some species of *Cladophora*, of which we possess so many, give a good idea of the nature of the filaments. [M. J. B.]

**ANÆCTOCHILUS.** A genus of terrestrial orchids, nearly allied to *Goodyera* and *Ætheria*, with creeping slender-jointed rhizomes, one or two radical leaves, and spikes of white or yellow flowers. Some of the species have the leaves traversed by beautiful silver or golden veins, on a rich green or purplish ground; hence they have become favourites in the gardens of the curious. There are other tropical terrestrial orchids, with similarly veined leaves, belonging to other genera, one of the commonest of which is *Phyllurus plicatus*.

**ANAGALLIS.** An interesting genus of Primworts, consisting of dwarf trailing herbaceous plants, annual or perennial roots, angular stems, opposite leaves in pairs or threes, and pretty axillary blue or red flowers. The Pimpernel, by which name the species are popularly known, are easily distinguished from the rest of the order by their conspicuous wheel-shaped, five-parted corolla, five stamens with bearded filaments, and especially by their many-seeded globular pods, opening when ripe by a transverse fissure all round, the top falling off like a lid. With the exception of *Centunculus*, an obscure weed, no other genus of the order presents this feature. Every one is familiar with the common red Pimpernel (*A. arvensis*). The *A. latifolia*, with blue flowers, scarcely differs from it, except in colour and the larger size of its blossoms. Of much greater interest are the Italian Pimpernel (*A. Monelli*), with still larger flowers and of stronger habit, and the *A. collina*, a Barbary species, with handsome light red tinted corollas, which, unlike those of the other species, remain expanded even in the absence of sunshine. It is probable that most of the varieties now cultivated in gardens, among which may be mentioned *A. Philippii*, with deep blue, and *A. Parkii*, with red flowers, are either hybrids or mere seminal variations of these two species. [W. T.]

**ANAGYRIS.** A Leguminous genus of two or three species, of which *A. fatida* is the best known; this is a large bush, with trifoliate leaves, entire elliptical leaflets, and axillary racemes of yellow flowers, much like those of the laburnum. The pod is narrow, compressed, and curved backwards; and from this circumstance the genus is named—*ana*, signifying back-

wards, and *gyros*, a circle. It is found in the South of France, Spain, and other countries bordering on the Mediterranean Sea; also in the Canary Islands. The seeds are kidney-shaped, violet in colour, and are said to be poisonous, like those of the laburnum. [A. A. B.]

**ANALOGY.** Resemblance to a thing in form, but not in function; or in function, but not in form. Corresponding with a thing in many points, but differing in more, or in points of more importance. Thus, the flowers of *Potentilla* and *Banunculæ* are analogous.

**ANAMIRTA.** A genus of plants inhabiting Malabar, Ceylon, and the Eastern Isles of India, and belonging to the *Menispermaceæ*. The flowers are unisexual and dioecious—that is, the male blossoms are borne on different plants from the female blossoms. The sepals are six in number; there are no petals; the stamens are numerous, but united into one parcel, forming a globular head. The ovaries of the female flower are three in number, attached to a short thick hemispherical receptacle; they become succulent and drupe-like in the fruit. The most important, if not the only species of this genus, is the *A. Cocculus*, the plant which produces the fruits known as *Cocculus indicus*. It is a climbing plant, with ash-coloured, corky bark. The leaves are stalked, more or less heart-shaped, smooth above, pale beneath, and provided with tufts of hairs at the junctions of the nerves, the larger of which radiate from the base of the leaf. The flowers are borne in pendulous panicles. The fruits are roundish or kidney-shaped; the outer coat is thin and dry, of a dark brown or black colour and wrinkled appearance; within this is a white hard shell, divided into two pieces; this encloses the whitish seed, which is very oily, of a crescent-like shape, and much smaller than the fruit, so that it never entirely fills up the cavity.

*Cocculus indicus* is imported from the East Indies, and is used for adulterating porter, though, very properly, a heavy penalty is inflicted upon brewers detected in so doing, and upon druggists who supply brewers, as it contains an acrid irritant poison, called picrotoxin. It is used to poison fish, and to increase the intoxicating properties of porter, being employed in the shape of a black extract. Its effects are to produce giddiness, convulsions, and insensibility. It has been occasionally used externally to destroy vermin, and in some skin diseases. [M. T. M.]

**ANANASSA.** A genus of tropical *Bromeliaceæ*, having rigid foliage, with sharp spines along the edge, distinguished among the inferior-fruited genera of the order, chiefly by its berries being consolidated with the bracts into a compound or syncarpous fruit, which is edible.

The Pine-apple, *A. sativa*, is generally believed to have derived its name from the great resemblance which the fruit

bears in its form to the cone of some species of the pine or fir tribe. It is universally acknowledged to be one of the most delicious fruits in existence. Three hundred years ago it was described by Jean de Lery, a Huguenot priest, as being of such excellence that the gods might luxuriate upon it, and that it should only be gathered by the hand of a Venus. It is stated to be a native of Brazil, and having been carried from thence to the West, and afterwards to the East Indies, cannot be regarded as indigenous to the tropical parts of Asia, Africa, and South America. It first became known to Europeans in Peru, where it is called *Nanas*, and under this name it was described in 1555 by Andre Thevet, a monk, who says it was often preserved in sugar. The plant is biennial, not unlike an *Aloe*, but the leaves are much thinner, and of a hard fibrous texture, with numerous short sharp spines on the edges. The fruit is produced on a short stem which rises from the centre of the plant, and bears a scaly conical spike, surmounted by a number of small spiny leaves called the crown. This conical body, after flowering, gradually enlarges and eventually becomes the rich and succulent Pine-apple we so highly prize. Besides being the first of dessert fruits, it is made into marmalades and various confectioneries, and is used to flavour rum. The earliest account of Pine apples being seen in England, is that of some having been received as a present by the Protector Cromwell. We next find them noticed by the celebrated Evelyn, from whose Diary we subjoin the following extract:—'August 9, 1661. I first saw the famous Queen Pine brought from Barbados and presented to His Majesty' (Charles II.); again under date of July 19, 1668, he observes, 'I was at a banquet which the King gave to the French Ambassador. Standing by His Majesty at dinner in the presence, there was of that rare fruit called the King Pine, growing in Barbados, in the West Indies. The fruit of them I had never seen. His Majesty cutting it up was pleased to give me a piece from his own plate to taste of; but in my opinion it falls far short of those ravishing varieties of deliciousness ascribed to it.' It has been conjectured that from the crowns of these Pines, Mr. Rose, the royal gardener, succeeded in raising plants, and that one of the latter might have produced the fruit he is represented, in a well-known picture, as presenting on his knee to King Charles II. as the first Pine-apple grown in England. It is just possible that such might have been the case, but, except in the picture above alluded to (of which a copy is in the possession of the Horticultural Society), we have no evidence to show that the Pine apple was then cultivated in the royal gardens, or at any other place in this country, until many years afterwards. For its introduction into Europe we are indebted to M. Le Cour, a Dutch merchant, who about the middle of the seventeenth century made an attempt to cultivate it in his garden at Drie-hock, near Leyden.

After a great many trials he at last hit upon a plan by which he obtained a sufficient degree of heat to produce fruit equally good, though not so large, as that produced in the West Indies. According to the best authorities, the first plants introduced into England were brought from Holland by the Earl of Portland in 1690. Twenty years afterwards we find Pines successfully cultivated by Sir Matthew Decker, in his garden at Richmond; and to this gentleman the honour has usually been ascribed of having first fruited the Pine apple in Britain, about the year 1712. From that time to the present every possible means that art and ingenuity could devise for the culture of this fine fruit has been adopted, and in no other instance, perhaps, has the care and skill of the gardener been attended with more signal success. Pine-apples having been produced in this country far surpassing in size and flavour the very best of those matured in a tropical climate. The difficulties which formerly attended the cultivation of the Pine-apple have disappeared since the mode of heating hothouses with hot water was introduced, and handsome fruits weighing from six to twelve pounds are by no means uncommon; but he heaviest on record, we believe, was grown in 1826 by Dixon, gardener to John Edwards, Esq., Rheola, Nenth, Glamorganshire, and weighed fourteen pounds twelve ounces! The most remarkable experiment, however, that has been made in pine-growing was one by Barnes, gardener to Lady Rolle, at Bliton, in Devonshire, who, in September 1845, cut some excellent fruit of four and six pounds weight from plants that had been exposed in the open air during the whole of the summer. Pine-apples are no longer a novelty, large quantities being annually imported and sold at a cheap rate in the principal towns throughout the kingdom. Like most of our cultivated fruits, they vary in quality and appearance; no less than fifty-two sorts being described in the *Transactions of the Horticultural Society* (2 ser. i. 1). The greater number have been introduced from abroad; but several have originated from seed in England. That which is now so commonly imported from the Bahamas is a sort called the Providence, one of the least valuable of the race.

[W. B. B.]

**ANANDRÆ.** A name sometimes given to Cryptogams on the supposition that they have no male organs. See **ASEXUAL PLANTS**. [M. J. B.]

**ANANDRIA.** A genus of the Composite family, and of the tribe *Mulsicæ*, in which the florets are two-lipped. *A. Bellidistrum* is a stemless herb of Siberia and Japan, having rosettes of stalked lyrate toothed leaves, covered with white down underneath, and arising from their midst a flower scape bearing a single head about half an inch across, containing numerous white or purple florets. When the plant is in flower the leaves are seldom more than

three inches long, but, when mature, are from five to six inches. The flower scape also lengthens after the flowers wither, and is often upwards of a foot in length. The naked receptacle and broad-beaked achenes terminating in a small cavity, are the characters which distinguish the genus from *Perdicium*, to which this plant was formerly referred. It has been cultivated in this country, and is the only species of its genus. [A. A. B.]

**ANAPAUSIA.** A genus of polypodiaceous ferns belonging to the *Acrosticheæ*, among which they are distinguished by having a portion of their fronds wholly fertile, and the veins of their fronds compoundly reticulated, with free divaricate veinlets in the areoles. The species are mostly found in the West Indies and South America, and form coarse-growing herbaceous plants with compound fronds, a portion of which are entirely sterile, and the remainder somewhat contracted and covered with the fructification. *A. vesper-tilio*, a Javanese species, has coriaceous linearly bilobed sterile fronds, and linear-lanceolate fertile ones. [T. M.]

**ANARRHINUM.** A genus of biennial, or perennial herbaceous plants, natives of Southern Europe, Northern Africa, and Syria, belonging to *Scrophulariaceæ*, and containing seven species. The radical leaves are generally rosulate, the cauline opposite or alternate, sometimes both on the same plant. The flowers are small in spike-shaped racemes. The calyx is deeply five-lobed, the corolla tubular and bilabiate, the upper lip erect, then reflexed, the lower patent. The stamens are included, four being fertile, and the fifth sterile and undeveloped. The ovary is bilocular, with many ovules. [W. C.]

**ANARTHRIA.** A genus of *Rubiaceæ*, containing five species of perennial plants, with flattened simple or branched stems, indigenous to the eastern shores of New Holland. The flowers are dioecious, and have six glumes. The male flower has three free stamens, with bilocular anthers; the female has three styles. The capsule is three-lobed and tri-locular, with a single seed in each locument. [W. C.]

**ANASARCA.** A condition of plants analogous to dropsy, though not always attended by extravasation. In extremely wet weather the tissues get gorged with fluid, and as the vegetative powers are generally lowered by the decrease of temperature, the contents of the cells are badly supplied, and, in consequence, their walls, unconsolidated, become subject to decay, which is soon exhibited in a variety of untoward symptoms. Fruit, in consequence, which has been produced in a wet season, is notoriously subject to decay, except compensated, as in the late ungenial summer, by a high state of the hygrometer, a circumstance which may perhaps account for the extremely small quantity of decay which has been ex-

perienced in our autumnal fruits. In some cases, as in elms, there is sometimes direct extravasation, and then the fluid accumulates, and at length forces its way through the bark, producing permanent ulcers. [M. J. B.]

**ANASTATICA.** A genus of *Cruciferae*, consisting of a single species, the Rose of Jericho (*A. Hierochuntina*), a small annual growing in the arid wastes of the extra-European Mediterranean region, from Syria to Algeria. The stem is short, branched in a corymbose manner at the top; the leaves obovate, with stellate hairs, the lower ones entire, the upper remotely toothed; the flowers are small and white, forming spikes along the branches; the fruit is a short pouch, with two ear-like projections at the top, and divided by a transverse partition within into two cells, in each of which there is a seed. This plant is interesting on account of its hygroscopic properties: when the plant is in flower, the branches spread rigidly, but when the seed ripens, the leaves wither and drop, and the whole plant becomes dry, each branch curls inwards, until the plant presents the appearance of a little ball of wicker-work at the top of the unbranched part of the stem. In this state it is soon loosened from the soil, and carried about by the wind, and often blown into the sea. When this happens, or the plant is otherwise withered, the branches unbend, and the pods begin to open by splitting longitudinally, so that, when thrown on shore by the waves, the circumstances are favourable for the production of fresh individuals in a locality remote from the original place of growth. The plant retains its property of expanding when moistened, and again curling up when dry for a long time. Specimens, collected ten years ago, exhibit the phenomenon as perfectly as ever. In Palestine it is called 'Kaf Maryan,' or Mary's Flower; and there is a tradition that the plant expanded at the birth of the Saviour. [J. T. S.]

**ANASTOMOSIS.** The angle formed by the union of veins, or of their branches.

**ANATHERUM.** A group of grasses, the species of which are now included in the genus *Andropogon*. [D. M.]

**ANATROPA.** A generic name given to a small, succulent, herbaceous plant from Syria, belonging to the natural order *Elatinaceæ*. Except that it has stipules, it differs in no respect from *Tetradlea*, to which it is consequently generally referred. [W. C.]

**ANATROPAL.** When an ovule is turned down upon itself, so that the foramen, or true apex, points to the base, and the chalazæ is at the apex.

**ANBURY.** A gouty nodular condition of certain roots, as turnips, arising from the presence of grubs. It must not be confounded with dactylorhiza, which is a

very different affection, and entirely independent of the attacks of insects. [M. J. B.]

**ANCHITEA.** P. Anchitea, a Brazilian writer on plants, is commemorated in the name of this genus of Violetworts, *Violacea*. The species are shrubs, with undivided leaves, and small white flowers in axillary tufts. The calyx consists of five unequal divisions, not prolonged at the base; petals, four, unequal, the hindermost one large, and prolonged into a spur; filaments very short; anthers fixed together, membranous at the top, two of them prolonged by means of their connectives into the spur of the petals. Fruit large, capsular, membranous, and bladder-like. Of *A. sulcatris*, a creeping bush, with a nauseous taste, and a smell of cabbage, the root is used as a purgative by the Brazilians, and as a remedy in skin diseases. *A. pyrrolia* is an ornamental stove-creeper, with white flowers. [M. T. M.]

**ANCHUSA.** A genus of *Boraginaceæ*, consisting of rough or hispid plants, most of which are natives of Southern Europe and the East, resembling *Lithospermum* and *Alkanna*, but with the nuts which form the fruit hollowed out at the base, and the corolla, which is from funnel-shaped to salver-shaped, closed by five scales at the throat; flowers purple, blue or yellowish, in scorpioid racemes, which are generally bracteated, and in pairs. Three species occur in Britain, but two of them appear to be doubtful natives. The evergreen Alkanet, *A. sempervirens*, has broad ovate leaves, those of the root large, and on long stalks; with sky-blue flowers in short twin racemes on short stalks, from the axils of the leaves. The common Alkanet, *A. officinalis*, has narrow oblong leaves, and deep purple flowers, in several racemes, at the top of the stems. The small Bugloss, *A. arvensis*, is often separated from the other species, under the name of *Lycopsis arvensis*, on account of the tube of the corolla being curved: it is a very bristly annual, with small pale blue flowers, and narrow oblong leaves, and is a common weed on cultivated ground. The first two species are often cultivated in gardens, but the biennial European *A. paniculata*, or *italica*, is the most common in flower borders, as its flowers are as large as a fourpenny piece, and bright azure blue. *A. capensis* is from the Cape of Good Hope. *A. tinctoria*, the Alkanet, is now called *Alkanna tinctoria*. [J. T. S.]

**ANCHITOUS.** Two-edged, as the stem of an Iris.

**ANCISTROCLADEÆ.** Under this name Planchon proposes to form a new natural order, out of the solitary genus *Ancistrocladus*—which see.

**ANCISTROCLADUS.** A genus of climbing plants, inhabiting the East Indies. Its prominent characters are the branches, some of which are curved and hook-like; the alternate, stalked, leathery leaves unprovided with stipules; inflorescence a

panicle; ten stamens in one row, five shorter than the others, all slightly adherent one to the other at their base; the anthers have a slightly prolonged crest at the top; the one-celled ovary has a single ovule at its base, and ripens into a sort of nut, crowned by the persistent calyx. The genus is by Planchon referred to a new order, *Ancistrocladeæ*, more nearly allied to *Dipterocarpaceæ* than to any other group. 'It combines,' he says, 'with the vegetation of *Nepenthes*, the leaves of *Lophira*, the stamens and stigmata of certain malpighiaceus plants, the adherent calyx of *Dipterocarpus*, the adherent ovary of *Symplocos*, the hook-like branches of *Hugonia*, and a peculiar fleshy fungus-like embryo, with a cylindrical rather long radicle, and a disc-shaped cotyledonary mass.' [M. T. M.]

**ANCOLIE.** (Fr.) *Aquilegia*.

**ANDEK.** In names formed from the Greek = the male sex or stamen: thus *monander* signifies having one stamen.

**ANDERSONIA.** A genus of squarrose-leaved shrubs, belonging to the natural order *Epacridaceæ*, containing several species, remarkable for the great beauty of their flowers and the singular structure of their leaves. They are natives of New Holland. The flowers are terminal, and solitary or in spikes. The calyx is coloured, five-partite, with two or more bracts. The corolla is subcampanulate, hypocrateriform, and five-lobed, the lobes bearded at their base. The five hypogynous stamens just appear beyond the throat of the corolla. The existence of a nectary, consisting of five scales, separates this genus from *Sprengelia*, with which it is otherwise identical. The ovary is five-celled, with many ovules in each cell. The fruit, a berry, is esculent. [W. C.]

**ANDIRA.** A genus of the Peaflower tribe, of the natural family *Leguminosæ*. About seventeen species are known, all of them trees of moderate height, with alternate unequally pinnate leaves, about one foot long, of five to ten pairs of leaflets. The stipules are sometimes large and persistent, or they are small and fall early. The flowers are often showy, and are disposed in axillary or terminal panicles—the reddish blue of their petals contrasting well with the often dark purple branches of the flower-stalks. The pod is one-seeded, drupaceous, and somewhat like a plum in appearance. All the species are natives of tropical America, but a variety of *A. inermis* is found in Senegambia. This species is called in the West Indies the Cabbage-tree. Its bark is anthelmintic, but requires great care in its administration, being powerfully narcotic. It has a sweetish taste, but a disagreeable smell, and is given in the form of a powder, decoction, or extract. The decoction is generally preferred, and is made by boiling an ounce of the dried bark in a quart of water, until it assumes the colour of Madeira wine. The effects of an over-dose

are vomiting, delirium, and fever: the antidote for this is lime-juice or castor oil. The powder, administered in doses of three or four grains, purges like jalap. The bark is known as Bastard Cabbage Bark, or Worm Bark; formerly it was used as a medicine in English practice, but its use is now obsolete. *A. retusa*, a Brazilian species, has purple flowers, having an odour of oranges, with a slight aroma: the fruit is said to smell like the tonka bean. Most of the species are beautiful objects when in flower. [A. A. B.]

**ANDRACHNE.** A genus of Spurge-worts, (*Euphorbiaceae*) comprising ten species; distributed over the Mediterranean region, N. India and China, one species occurring in Arkansas. They are perennial herbs of no beauty, with erect or prostrate stems, furnished with alternate, shortly-stalked leaves, having rounded or ovate and entire blades of a pea-green colour, varying from a quarter of an inch to two inches in length; while the small greenish flowers—which are sterile and fertile on different plants—are borne singly, or two to four together, in the axils of the leaves. The sterile flowers have a calyx of five to six sepals, a like number of petals, five entire or bifid glands opposite the petals, and five stamens, slightly united below by their filaments, and surrounding an abortive ovary. The fertile flowers have a like calyx and corolla, rather larger glands, and an ovary surmounted by a three-branched style, each of the branches forked. The fruits are trilobed capsules, of the size of peas, with three cells, and two seeds in each cell. [A. A. B.]

**ANDREZA.** A genus of Mosses named after Andrea, a Hanoverian Doctor. It is remarkable for having a capsule which splits into four or sometimes six valves, which, however, do not expand as in *Jungermannia*, but adhere at the apex to which the columella is attached. The capsule is always sessile, even to maturity, but is at length supported by the elongated base or pseudopodium. In consequence of this arrangement, the calyptra does not burst so soon as in most other mosses, as it is ruptured by the swelling of the capsule and not by the elongation of the peduncle. The species are Alpine or sub-Alpine, occurring on quartzose or granitic, never on calcareous rocks, and are found in cold or temperate regions of either hemisphere, or at considerable heights in warmer countries, as in the Himalayas. Four species in which the leaves have a central nerve, occur in this country, while in the others the leaves are nerveless. [M. J. B.]

**ANDREACEAE.** A natural order, or, according to some, a distinct tribe of Mosses. They do not, however, differ essentially, being distinguished mainly by the longitudinal splitting of the valves at maturity. It consists of but two genera, *Andreaea* just described, and *Acroclisma*, an Antarctic genus, distinguished by the cylindrical capsule splitting into four or eight valves

at the apex only. All the species are of a peculiar dark hue, and the leaves, which are of a close texture, are of a beautiful yellow or golden brown under the microscope. [M. J. B.]

**ANDROGYMBIUM.** A genus of *Melanthaceae*, containing three or four species from the Cape of Good Hope. They are plants with tunicated bulbs, and simple, short, subterranean stems, crowned with from two to four ovate, lanceolate, or linear leaves, and having one to nine flowers in short spikes, hid in coloured foliaceous bracts. [W. C.]

**ANDROECIUM.** The male system of a flower. The stamens taken collectively.

**ANDROGLOSSUM.** A genus founded on a single species, *A. reticulatum*, a native of the Island of Hongkong. It seems to belong to the natural order *Rhamnaceae*, the arrangement of the stamens being precisely the same as in that order; but it differs from it in the structure of the ovary, the carpels being almost if not quite distinct, and the ovules, two in each carpel, horizontally attached to the axis, instead of being solitary and erect from the base. The calyx is five-partite; the corolla five-petaled; the five stamens are opposite to and inserted in the petals; there are two styles. The fruit from the abortion of one of the carpels, is simple, spherical, and subdrupaceous, with a crustaceous covering. [W. C.]

**ANDROGYNOUS.** A term applied to such kinds of inflorescence as consist of both male and female flowers.

**ANDROMEDA.** A genus of *Ericaceae*, consisting of shrubs and trees having various habits, and a wide geographical range; but found chiefly in boreal districts, or at considerable heights on mountains in North America, Europe, and Asia. The genus has a calyx of five nearly or partly distinct sepals, valvate in the early bud, but very soon separate or open. The corolla is ovate or campanulate, five-toothed, and deciduous. The stamens are ten in number, with the anthers fixed near the middle; the cells generally opening by a terminal pore. The ovary is five-celled, with many ovules in each cell. The style is simple. The fruit is a dry capsule, superior, globular, five-celled and five-valved, and loculicidal, the dissepiments being from the middle of the valves.

The genus is by some modern botanists limited to the single British species, *A. polifolia*; but it is usually extended to include a very large number of species. So extended, it is divided into the following sub-genera:—1. *Andromeda proper*, boreal herb-like plants, with calyx five-cleft, corolla sub-globose, filaments bearded, anthers having a slender ascending awn, and seed smooth. 2. *Cassiope*, Arctic and Alpine under-shrubs, with calyx five-parted, without bracts, corolla campanulate, anthers fixed by the apex, and having a long

recurved awn, stigma truncate, and seeds smooth and wingless. 3. *Ossandra*, boreal shrubs, with calyx five-parted, and having two bracts, corolla tubular, anthers without awns, and seeds flattened and wingless. 4. *Zenobia*, North American shrubs, with calyx five-toothed, corolla campanulate, deeply five-parted, anthers two-awned, and seeds angular. 5. *Leucothoe*, North American shrubs, with calyx five-parted, corolla tubular, five-toothed, anthers unked, or with one or two awns, and stigmas broadly capitate. 6. *Pieris*, Nepal trees or shrubs, with calyx five-parted, corolla tubular or ovate, anthers two-awned, and stigmas truncate. 7. *Agave*, tropical American evergreen shrubs, with calyx five-parted, corolla ovate, anthers with two bristles, stigmas capitate, and seeds angular.

The members of this genus are more or less narcotic. *A. polyfolia*, the only British species, but found also in peat bogs throughout the north of Europe, Asia, and America, is an acrid narcotic, and proves fatal to sheep. Similar properties have been observed in the United States in *A. maritima* and other species. The shoots of *A. ovalifolia* poison goats in Nepal. Dr. Hornfield states that a very volatile heating oil, with a peculiar odour, used by the Javanese in rheumatic affections, is obtained from one of the species. [W.C.]

**ANDROPHORE.** The tube formed by monadelphous filaments, as in mallow.

**ANDROPOGON.** An extensive genus of grasses, typical of the tribe *Andropogoneæ*, which, according to Steudel's *Synopsis Plantarum Graminearum*, contains 458 species. The flowers are polygamous. The species are mostly natives of the warmer parts of the globe, especially South America; none of them British. Among the more interesting kinds, the Sweet-scented Lemon Grass, *A. Schananthus*, may be mentioned, which is a native of Malabar, and well-known in British gardens as a stove conservatory plant. The fresh leaves, when bruised, emit a delightful odour, and when roasted are used in India for medicinal purposes. One of the grass oils is yielded by a species of this genus. (See *Brewster's Journal*, ix. 333.) *A. muricatus*, called in India *khus*, is employed there for making covers for palanquins, and screens, &c. (see *Lindley's Vegetable Kingdom*, p. 113).—The roots are woven neatly into screens or mats, and suspended before the doors or windows, so that the breeze, in passing through them, is cooled and regains a portion of its healthy elasticity, while a slight but very agreeable fragrance is diffused around. Lady Calcott in the *Scripture Herbal*, considers *A. Calamus aromaticus* to be the Sweet Cane of Isaiah, the Sweet Calamus of Exodus, the Calamus of the Canticles and of Ezekiel. Dr. Royle also considered the plant of that name described by Dioscorides to be the Sweet Cane and 'rich aromatic reed from a far country' of Scripture. Steudel does not enumerate

this species under the genus of *Andropogon*, nor give any synonym of it. [D.M.]

**ANDROSACE.** Mountain plants, with flowers nearly allied to the Primrose, from which they differ principally in having the mouth of the corolla contracted. They are found on the mountains of Europe, from Siberia to the Pyrenees, and are well adapted for growing on rockwork, though not easy of culture. The leaves, which vary in shape in the different species, are tufted, and grow close to the ground; the flowers are either white or pink, and grow on a scape or leafless stalk, in umbels; they are usually small, and inconspicuous. Some of the species are annuals, and some perennials; only one is a biennial. They vary in height from two to six inches. [C.A.J.]

**ANDROSÆMUM.** Under the name of *A. officinale*, the Tutsan, *Hypericum Androsæmum*, is sometimes separated from the rest of the *Hypericeæ*, from which it differs chiefly in having a berry-like capsule; but the genus is not generally adopted. [T.M.]

**ANDROSTEMMA.** A genus of *Hemodoraceæ*, nearly allied to *Conostylis*, containing a single species, from Swan River Colony, New Holland. It is a rushy plant, of no beauty, although its flowers are an inch and a half long, for they are green, and buried among the leaves. [W.C.]

**ANDROUS**, in the composition of words derived from the Greek, refers to the stamens; thus, *mon-androus* signifies having one stamen, &c.

**ANDRYALA.** A family of evergreen herbaceous plants, belonging to the natural order *Compositæ*, growing to the height of about half a foot, and having yellow flowers. Two species are found in dry stony fields about Nice, near the Var; the others are natives of Madeira and the North of Africa, and, when cultivated in this country, require the protection of a greenhouse. [C.A.J.]

**ANETE.** (Fr.) *Atrus glutinosus*.

**ANEILEMA.** A genus of *Commelynaceæ*, the flowers of which have a six-parted unequal perianth, the three outer divisions or sepals persistent, and the three inner deciduous; six stamens, of which three are dissimilar, scarcely polliniferous; and no involucre. It is principally distinguished from *Commelyna* by the latter circumstance. There are several species, natives of New Holland and India. [T.M.]

**ANEMIA.** often erroneously written *Anelmia*. A genus of schizomaceous Ferns, belonging to the section *Schizæen*, in which it is distinguished by having the fructifications pinnulate on distinct fronds, or on lateral branches of the fronds, and the veins free. The separate branches of fructification produce the appearance of a flowering plant, with a spicate inflorescence. There are numerous species of South America and the West Indies, some

of which are of a very ornamental character, and much prized in gardens. One of the most beautiful is *A. adiantifolia*, a species having the barren branch triangular and tripinnatifid, and the two fertile branches erect, rising from its base, and bearing a cylindrical spike of small fertile segments. Several species, with a similar arrangement of the parts, have the sterile branch pinnate. Other species, as, for example, *A. millefolia* and *A. buntifolia*, have the fertile parts distinct, rising from the base. One species, *A. Wightiana*, is found on the Neilgherry Hills of India, and another, *A. Dregeana*, is met with in South Africa and Natal. [T. M.]

**ANEMIDICTION.** A genus of schizaeaceous Ferns, distinguished from *Anemia* only by the reticulated venation of its fronds. It is consequently included in that genus by those who do not admit the generic importance of the venation in ferns. The principal species, *A. Phyllitidis*, occurs in various forms in the West Indies and South America, and is a fine herbaceous species, with pinnate sterile branches, and tall, compactly-panicked fertile ones. [T. M.]

**ANEMIOPSIS.** A genus of the small family *Saururac*, peculiar to California and New Mexico, and represented by a single species, *A. californica*, a semi-aquatic perennial herb, with stalked and nearly smooth root-leaves, like those of the *Sprei*, *Rumex Acetos*, but of a much thicker texture. The flower scape, nearly a foot in length, and exceeding the root leaves, bears near its middle a leafy bract (which often produces in its axil a young plant), and terminates in a compact cone of small green flowers, surrounded by an involucre of six oblong petal-like leaves of a white colour, spotted with red, so that the whole head has some resemblance to an anemone flower. The flowers are destitute of calyx and corolla, have six to eight stamens seated on the top of an ovary, which is one-celled, with three bundles of ovules hanging from the top of the cell, and crowned with three short styles. The plant is in cultivation in this country. [A. A. B.]

**ANEMONE.** A large genus of *Ranunculaceae*, generally distributed in temperate regions—most numerous in alpine situations in the warmer districts. They have tuberous or thickened root-stalks and root-leaves, often ternately divided or cleft. The stem, or rather scape, is leafless, and often unbranched, with an involucre below the flower, formed by a whorl of three (rarely two) bracts. When the scape is unbranched, there is only one involucre; when branched, each flower has one, and the branches spring from the interior of the involucre, together with the peduncle, which bears the central flower. The flowers are handsome, for, though the petals are absent in single flowers, the sepals are brightly coloured, especially on their inner faces. The flowers very readily become double by the conversion of the numerous

stamens into narrow petals; this is often seen in gardens, but occurs even in wild plants of some species found in the South of Europe—a very unusual circumstance.

The genus forms three groups or sections. (1) *Anemone proper*, or *Anemanthus*, of Endlicher, in which the carpels terminate in a short point (not a feathery tail), and the involucre is remote from the flower. (2) *Hepatica*, with the carpels as in *Anemanthus*, but the involucre close to the flower, resembling a calyx. (3) *Pulsatilla*, in which the carpels end in a long feathery tail, formed by the persistent styles, which elongate after the flower fades. Of the first section, three species occur in Britain. The Wood Anemone, *A. nemorosa*, is the only one truly native; it has white flowers, sometimes tinged with purple on the outside. *A. ranunculoides*, a common European plant, naturalised in a few stations in Britain, has bright yellow flowers, otherwise like the wood Anemone. *A. apennina*, a native of Southern Europe, also naturalised in a few British localities, has the flowers bright blue on the inside of the sepals, which are narrow, and more numerous than in the other two; the root-stalk is also shorter and thicker. The last two are often cultivated in gardens, as well as the more showy Japan Anemone, *A. japonica*, which has ternate leaves, branched flowering stems, and large purplish-red flowers. The Star Anemone, *A. hortensis*, or *stellata*, has ternate leaves, with the segments not finely divided, unbranched flower-stalks, and star-like flowers, smaller than those of the Japan Anemone and very variable in colour; and the Poppy Anemone, *A. coronaria*, which, like the last, is a native of the Mediterranean region, has ternate leaves, with the divisions cut into fine segments, unbranched flower-stalks, and large flowers, with broad sepals, very variable in colour—scarlet, purple, blue, whitish, striped, or with an eye of a different hue from the rest of the flower. The last two, and especially the Poppy Anemone, are florists' flowers. [J. T. S.]

**ANEMONE, RUE.** *Thalictrum anemonoides*.

**ANEMONOPSIS.** A genus of *Ranunculaceae*, containing a single species, *A. macrophylla*, a native of Japan. It is allied to *Helleborus*, having three to five follicles to form the fruit. The flower, however, resembles in aspect that of an *Anemone*, whence the name. The calyx has nine sepals; the corolla ten petals; and the leaves are three or four times ternately divided, resembling an *Actaea*. [J. T. S.]

**ANEMOSIS.** The condition known in timber by the name of wind shaken. A trunk which is apparently sound externally, proves, when felled, to have given way in the direction of the concentric layers of which it is composed, so that the connection between them is more or less completely broken. This occurs in many kinds of exogenous timbers, and is no less common in foreign woods than in

those of native growth, being, as it is supposed, due to the pressure of extremely violent gales. This, however, is very doubtful, the effect being more probably due to frost or lightning. Wind, however, may be injurious to trees without producing absolute fractures or separation of parts, by causing too rapid evaporation and in consequence chilling the tissues to such a degree as to retard development, or induce an unhealthy condition, or temporary sterility. [M. J. B.]

**ANESORHIZA.** A genus of *Umbelliferae*, containing seven or eight species of biennial or perennial herbaceous plants, with one or more fusiform roots: natives of the Cape of Good Hope. The root of *A. capensis*, known vulgarly as Anyawortel, is used as an esculent. The radical leaves are petiolate, and two or three times pinnatisect; those of the stem are scale-like. The umbels are few or many radiate: in some species being as few as three, in others as many as twenty-eight radiate. The limb of the calyx is five-toothed and persistent. The petals are elliptical and acuminate. The involucre and involucrels are many-leaved, the margins of the leaves being often scarious. [W. C.]

**ANETHUM.** The name applied to a genus of Umbelliferous plants, which is distinguished by the absence of involucre to the umbel, by the absence of the limb or upper part of the calyx, by the fruit being flattened from back to front, provided with a membranous border or wing, and with six ridges, three on each half of the fruits. In each of the furrows, between these ridges, is placed a broad channel, or vitta, filled with volatile oil. The Common Dill, *A. graveolens*, which in appearance resembles the fennel, is cultivated in herb gardens in this country for the sake of its fruits, and is a native of the south of Europe, Egypt, the Cape of Good Hope, &c. The fruits, or as they are commonly but erroneously called, the seeds, when distilled with water, furnish an oil on which the carminative effects of the plant depend. It is generally used in the form of dill water, to relieve flatulence in children, and to prevent the griping properties of some purgative medicines. The plant and the fruit are used as condiments in the East. It is supposed to be the plant which is called Anise in the New Testament narrative. [M. T. M.]

**ANETIA.** A genus of *Homalinee*, containing a single species. From tropical Africa. It is a shrub with alternate shortly petiolate leaves, and small cinereous flowers in branched spikes. It is nearly allied to *Homalium*, but differs from it in having a double series of stamens and glands, fifteen of each, that is three times the number of the calyx segments, and in having five diverging styles. [W. C.]

**ANETIUM.** A genus of polypodiaceous ferns, sometimes referred to the *Aceratichne*, but more closely allied to

the *Hemionitideae*, among which it is distinguished by having the veins of the fronds uniform, reticulate, and the sori sporadic, or dispersed, sometimes reticulated following the veins, and in some places distributed on the surface, but everywhere partial, as if scattered. The species *A. obtusatum*, is a West Indian and South American plant, producing narrowish simple fronds. [T. M.]

**ANETTE.** (Fr.) *Lathyrus tuberosus*.

**ANEURA, ANEUREÆ.** The name of a division and genus of frondose *Jungermanniaceae*. *A. multifida* and *A. pinguis*, found on the margins of ponds, on the walls of wells, and in similar damp situations, associated with *Pellia*, differ from that genus in having more divided and irregular ribless fronds, with the fruit marginal and ventral, the capsule oval or oblong, and the elaters attached to the tips of the valves. *Aneura* is the only genus of the division *Aneura*, a name indicative of the ribless fronds. [M. J. B.]

**ANFRACTUOSE.** Twisted or sinuous, like the anther of a cucumber.

**ANGELICA.** A family of Umbelliferous plants, the several species of which inhabit Europe and America. The name was given as a record of the angelic virtues possessed by some of the species; for not only was it a singular remedy against poison, the plague, all kinds of infection, and malaria; but it was invaluable against witchcraft and enchantments. The British species, *A. sylvestris* is a tall and stately plant, five or six feet high, with a polished stem, most frequently tinged with purple and covered with a glaucous bloom like that of a plum, much branched, bearing large compound leaves covered with a bloom like that of the stem, and at the extremity of each branch a large convex umbel of white flowers tinged with pink. It is common on the banks of rivers in withy-holts and other watery places, and may often be distinguished at a considerable distance by the large egg-shaped expansions of the leaf stalks, which serve as an integument for the as yet unexpanded flowers. The plant is now little regarded for any intrinsic virtues it may possess; but it forms a picturesque addition to the landscape, and may be made very useful in the garden by cutting the hollow stalks into convenient lengths and placing them about in the shrubs as traps for earwigs. Candied Angelica is made from the stalks of an allied plant, *Archangelica*. The appearance of a tall species of this genus growing in Kamtschatka is shown in plate 18. [C. A. J.]

**ANGELICA.** The garden name for *Archangelica officinalis*.

**ANGELICA TREE.** *Aralia spinosa*.

**ANGELICO.** *Ligusticum acutifolium*.

**ANGELIQUE.** (Fr.) *Archangelica officinalis*. — DE BOHÈME. *Trochescanthus*

*nodiflorus*. — **SPINEUSE**. *Aralia* *sp.*  
*nosa*.

**ANGELONIA**. A genus of *Scrophulariaceae* distinguished by its five-cleft or five-parted calyx; its short-tubed corolla, with forked throat, and somewhat two-lipped limb: the upper lip very blunt, two-lobed, the lower one longer, three-lobed with the middle lobe saccate at the base; four didynamous included stamens, and a two-celled many-ovuled ovary. The species, which are rather numerous, inhabit South America, and form erect or procumbent herbs, with opposite leaves alternate on the upper part of the stems, and solitary one-flowered axillary or racemose peduncles. *A. salicariifolia* is a pretty perennial species, with tallish stems, lance-shaped leaves, and a long racemose inflorescence consisting of light purple flowers. *A. angustifolia* is similar but dwarfer. The species have no particular use, but are ornamental. [T. M.]

**ANGIOPTERIDÆÆ**. A section of the marattiaceous division of marattiaceous Ferns, in which the spore-cases are free, and set close together, lucc to lucc, in two opposite contiguous lines. [T. M.]

**ANGIOPTERIS**. A noble genus of marattiaceous Ferns, representing the group *Angiopteridea*. The genus is eastern, being common in India, Ceylon, and the islands of the Eastern Archipelago. There are probably but few species, though they have been very much extended by De Vries, the author of a monograph of the family. The differences observed perhaps rather indicate varieties than species. The plants form a large round massive rhizome or root-stalk, covered with the great scale-like bases of the fronds, and from this solid mass rise up the stout stipites, supporting the very large bipinnated fronds, the pinnae of which are articulated on the rachides. The genus is known by its spore-cases being destitute of any elastic or jointed ring, and by having oblong distinct dorsal sori longitudinally bisected, the spore-cases being separate though crowded into two opposite linear series. The original species, *A. erecta*, was found in the Society Isles. *A. angustifolia*, a Philippine island plant, is described as having a cylindrical caudex, three feet high; the other species, so far as they are known, have the caudex of a depressed globular form. These plants form noble objects when cultivated in our out-houses, but require much space. [T. M.]

**ANGIOSPERMÆ**. In modern classifications all Exogens are divided into those whose seeds are enclosed in a seed-vessel, and those with seeds produced and ripened without the production of a seed-vessel. The former are *Angiospermae*, and constitute the principal part of the species; the latter are *Gymnospermae*, and chiefly consist of Conifers and Cycads.

**ANGLE-POD**. A common name for *Gonolobus*.

**ANGOLA WEED**. *Rumex* *purpureus*.

**ANGOPHORA**. A genus of New Holland plants, belonging to the Myrtle family, *Myrtaceae*. They are large trees, with large, opposite, not dotted leaves. The flowers, which are of a white or yellow colour, are arranged in a corymbose manner, and have their calyx divided into five or six segments, a circumstance that serves to distinguish them from the members of the genus *Eucalyptus*; their petals are free; the stamens are distinct; the fruit is dry, dehiscent, many-celled, containing several seeds, which are not winged. Some of the species furnish a dark-coloured stringent gum. [M. T. M.]

**ANGRECEUM**. The tropics of Africa, and its islands, some parts of the West Indies, and the Cape Colony, yield this remarkable genus of Orchids, one of whose species produces the largest flowers known in the order—the sepals and petals and prodigious spur extending to the length of more than a foot in *A. sesquipedale*, a native of Madagascar. The species are, however, for the greater part small-flowered. A whole section of them consists of leafless plants, clinging to the branches of trees by their flat bands, representing roots, as in *Aerides totiaia*. The finest species, after Madagascar, are from the West of Africa, where they assume some extraordinary forms. None are found except in the hottest latitudes. The leaves of *A. fragrans* are very fragrant, and are used in Bourbon as tea, under the name of Faham; it has been introduced into France.

**ANGUILLARIA**. A genus of *Melanthaceae*, containing a few species from New Holland. They have the leaves and roots, and the general habit of *Melanthium*, with the structure of *Ornithoglossum*. [W. G.]

**ANGULOA**. A genus of very remarkable terrestrial Orchids, inhabiting the forests of tropical America. They have round, ribbed leaves, and short leafy scapes, bearing single large fleshy flowers, either white, yellow, or spotted with crimson on a pale yellow ground. One of them grows in the Equator, at the height of 7,000 feet above the sea. Six or seven species are cultivated in this country.

**ANGURIA**. Under this name are included certain plants belonging to the gourd family, *Cucurbitaceae*. They are natives of South America, and have lateral tendrils, male and female flowers distinct, but on the same plant: the male flowers provided with two distinct, not united stamens; and the fruit a gourd. Some of the species are cultivated. [M. T. M.]

**ANHALONIUM**. A genus of South American *Cactaceae*, containing two species of napiform plants. The genus approaches *Mammillaria* in the arrangement and structure of its flowers, and has by some been made a section of that genus; but its fruit and seed unite it on the other hand with *Echinocactus*. [W. G.]

**ANIA.** A genus of terrestrial orchids of little interest, related to *Bletia*. They have plaited radical leaves, and flowers in spikes. Only two are known, inhabiting the hottest parts of Asia.

**ANTIA.** A Gulian plant, probably *Lauracens*, described by Aublet, but which has not since been recognised.

**ANIGOSANTHUS.** A curious and handsome genus of *Hamodoraceæ*, distinguished by having its woolly, tubular, elongated, often-curved perianth connate with the ovary, but at length deciduous; the limb six-cleft, and turned to one side; six stamens inserted in the throat; a filiform style and simple stigma; and a three-celled ovary, containing numerous ovules. The species, which are not very numerous, are herbs of the Australian continent, producing linear-ensiform leaves, slightly sheathing at the base, and a tall flower-scape, supporting a branching subcorymbose head, or short raceme of large and often showy flowers. The outer surface of the perianth, and the upper part of the flowering stem, are clothed with a peculiar short dense pile of branching coloured hairs, which are very curious objects when slightly magnified. Several of the species have found their way to our greenhouses, where they form desirable plants, on account of their distinct and peculiar, and not unornamental aspect when in flower. The flowers last a considerable time. One of the best-known species is *A. Manglesii*, a perennial tufted-growing plant, with glaucous green leaves, a foot to eighteen inches long, and an erect branched stem, clothed with a short thick crimson felt of the branched hairs above alluded to. The flowers are arranged on the branches in short terminal spiked racemes, and are two to three inches long, curved, clothed with velvety hairs, which, for the greater part of the length of the tube, are of a bright green colour, and on the peduncles, as well as the swollen base of the perianth enveloping the ovary, are rich crimson. Another species well known in gardens, *A. coccineus*, has a dichotomously forked inflorescence, and flowers of a dull crimson below, and green towards the tips. In another beautiful species, *A. pulcherrimus*, in which the inflorescence is branched and loaded with flowers, the colour of the short velvety hairs on the flowers is bright yellow, while those on the stems are scarlet, curiously branched, on a yellow ground. *A. tyranthinus*, again, has the paniculated branches and copious flowers clothed with dense tomentum of the richest Tyrian purple; while in *A. fuliginosus*, which has been called a flower of mourning, the upper parts of the stem, and the lower parts of the flower, are downy, as if covered with black velvet. These species are all from the Swan River district. [T. M.]

**ANIME.** A resin procured from *Hymenocleis* *Courbaei*. The name is also applied to other clear varnish resins.

**ANIS.** (Fr.) *Pimpinella Anisum*. — **ÉTOILE**, or **DE LA CHINE.** *Illicium anisatum*. — **DES VOSGES.** *Carum Carui*.

**ANISADENIA.** A genus of the order *Linacæ*, containing two species, from the Himalayas, plants having the appearance of *Trientalis*, with a simple erect stem, bearing a number of alternate, entire, membranaceous leaves at its summit. The calyx and corolla consist of five parts. The petals are unguiculate. There are five filiform fertile, and five short barren stamens. The ovary is sessile, and trilocular, with two ovules in each cell. There are three filiform styles. [W. C.]

**ANISE.** *Pimpinella Anisum*. — **STAR.** *Illicium anisatum*.

**ANISEED TREE.** A common name of *Illicium*.

**ANISOCALYX.** A genus of *Scrophulariaceæ*, containing a single species, found on the margins of streams in the island of Hong Kong. The calyx is unequally five-partite; the corolla is deciduous, and nearly equally five-partite. There are four didynamous stamens, scarcely longer than the corolla, with oblong purple and bilocular anthers; the style has a simple capitate stigma. [W. C.]

**ANISOCHETA.** A genus of the Composite family (*Compositæ*). There is but one species, which is a native of Caffreland. It is a sub-climbing shrub, with alternate, ovate, coarsely-toothed leaves, and terminal panicles of flower-heads. The genus is nearly related to the *Ageratum* of our gardens, but differs in habit, as well as in the scales of the pappus and in the form of the achenes. It is a plant of no beauty. [A. A. B.]

**ANISOCHILUS.** A genus of *Labiatæ*, consisting of annual or perennial herbaceous plants, natives of Asia, chiefly of India, and containing nine species. The verticillasters are in ovate-oblong, or cylindrical terminal spikes, compact and imbricate; the floral leaves are bract-like. The calyx is ovate, swollen below, contracted above. The tube of the corolla is bent down after leaving the calyx; the throat is inflated; the upper lip is three or four-lobed, the lower lip is longer, entire, and concave. There are four stamens, and a bifid style. [W. C.]

**ANISODUS.** A genus of plants belonging to the *Solanum* family, or by Miers referred to *Athopææ*. Its name is derived from its calyx, which is irregularly five-toothed, a circumstance which distinguishes it from *Hyoscyamus*, or the henbane genus. *A. luridus*, a Nepalese plant, is common in cultivation; it has a tap-shaped root, alternate leaves, which are stalked, oval, somewhat woolly on their under surface; the greenish yellow bell-shaped flowers are borne on axillary flower-stalks, and the fruit bursts by a transverse crack, like that of the henbane. [M. T. M.]

**ANISOMELES.** A genus of *Labiata*, containing eight species, natives of South-eastern Asia, the Mauritius, and tropical Australia. They are herbaceous plants, having the habit of *Stachys*. The terminal verticillasters are dense and many-flowered, or lax and few-flowered; the axillary are few-flowered. The calyx is ovate, tubular, and five-toothed. The corolla is the same length as the tube of the calyx: its upper lip is erect, oblong, and entire; the lower lip has the two lateral lobes, ovate and obtuse, the middle one emarginate and bifid. The stamens, four in number, are longer than the upper lip. The style is bifid at the apex. *A. malabaricus* has the reputation of being a tonic and febrifuge, and is so used by the natives of India. [W. C.]

**ANISOMERIA.** A genus of *Phytolaccaceæ*, containing a single species from Chili. It is so nearly related to *Phytolacca* that it is generally considered as a subgenus, differing from the true *Phytolacca* in the inequality of the lobes of the calyx, the ascending stamens, and the absence of an elevated central axis, leaving the ovaries free at their inner edge. [W. C.]

**ANISOMEROUS.** When the parts of a flower are unequal in number. The same as *Unsymmetrical*.

**ANISOPTERA.** A genus of *Dipterocarpeæ*, containing six species of trees, natives of the Islands of the Eastern Archipelago. They are nearly related to *Dipterocarpus*, but differ from it in having alternate leaves, and in the stamens, twenty-five in number, having their short filaments united together at the base. [W. C.]

**ANISOTES.** A genus of *Lythraceæ*, founded on the Brazilian *Lythrum anomatum*, which differs from *Lythrum* in having irregular flowers, the upper pair of petals being much larger than the rest, and the stamens only six. [J. T. S.]

**ANISOTOMA.** A genus of *Asclepiadaceæ* from the Cape of Good Hope, consisting of climbing herbs, with heart-shaped or kidney-shaped leaves, and small lateral umbels of subsessile flowers having a downy corolla. [T. M.]

**ANISOTOME.** A genus of *Umbellifera*, containing three or four species, natives of Auckland and Campbell Islands. They are amongst the largest and noblest plants of the natural order to which they belong, attaining a height of six feet, and bearing large umbels of rose-coloured or purple flowers. The stem is strong, erect, and furrowed. The leaves are large, petiolate, and two or three-pinnate. The flowers are dioecious, with the calyx margin five-lobed, and one or more of the lobes longer and more lanceolate than the remainder. In the male flower there are two rudimentary abortive ovaries, with the styles as mere points on their inner margins. In the female flowers the ovaries are conical, and terminate in long stout recurved styles, capitate at the extremity. The furrowed

seeds are covered with a blackish testa. The whole plant of *A. latifolia*, when bruised, emits an aromatic smell. [W. C.]

**ANNOTINOUS.** A year old. *Rami annotini* are branches one year old.

**ANNUAL.** Flowering and fruiting in the same year when raised from seed.

**ANNULAR.** Having the form of a ring, as in certain embryos.

**ANNULATE.** Surrounded by elevated rings or bands, or by scars in that form.

**ANNULUS.** A ring, as that which surrounds the spore-case of a fern, or the peristome of a moss; or the membrane remaining round the stipe of an agaric when the cap has expanded. In the latter case, it is a membranous or filamentous veil, inserted on the one hand round the stem, and on the other into the edge of the pileus, so as to cover the organs of reproduction.

**ANODA.** A genus of *Malvaceæ* differing little, if at all, from *Sida*, except in the fact that its peduncles are not jointed, from which circumstance also its name has been derived. The species are natives of tropical America, north of the equator, and are herbaceous plants with solitary violet or yellow flowers. Some of them are in cultivation. [M. T. M.]

**ANOMALOUS.** Irregular, unusual, contrary to rule.

**ANOMATHECA.** A small genus of pretty Iridaceous bulbs, inhabiting South Africa. The genus is distinguished by having a hypocotyliform perianth with a filiform triquetrous tube constricted at the throat, and a six-parted limb of oblong spreading segments, of which the three hinder ones are approximate; three subsecund stamens inserted in the throat of the perianth, and having short filaments; a filiform style bearing three narrow linear stigmata; and an inferior roundish ovate ovary, three-celled, containing many ovules. *A. cruenta* is a very pleasing dwarf plant, often seen in gardens. This produces a stem six to twelve inches high, furnished at the base with two-ranked, narrow, sword-shaped leaves, branched above, and terminating in a subsecund spike of flowers, of which the long slender tube is whitish, and the limb rich carmine crimson; the three lower segments have also a deep blood-coloured basal spot. There are one or two other species. [T. M.]

**ANONA.** A South American and West Indian genus of shrubs and trees, from which the name of the order to which they belong, *Anonaceæ*, is derived. The generic characters are a calyx of three minute sepals, united at the base; a corolla of six petals in two rows; the stamens numerous, with linear, two-celled anthers surmounted by an oval crest; numerous ovaries placed on a rounded receptacle and partly united together, becoming completely fused when

mature into a many-celled, fleshy, oval or rounded fruit.

Several species of this genus are cultivated in tropical countries for the sake of their fruits. The Sour-sop of the West Indies is the fruit of *A. muricata*. It is of considerable size, often weighing upwards of two pounds; it is greenish and covered with prickles, the pulp is white, and has an agreeable slightly acid flavour. The

*Annona squamosa.*

Sweet-sop is the fruit of a tree, *A. squamosa*, native of the Malay Islands, but extensively cultivated in the East and West Indies. The fruit is ovate, covered with projecting scales, the rind is thick, but encloses a luscious pulp, concerning which, however, tastes differ; it appears to be highly esteemed by the Creoles while the Europeans think lightly of it. The fruit grows in the Indian Archipelago; is said to possess a finer flavour than that grown in the West Indies. The leaves of this plant have a heavy disagreeable odour and the seeds, according to Royle, contain an acrid principle, fatal to insects, on which account the natives of India use them powdered and mixed with the flour of Gram (*Cicer arietinum*) for washing the hair. The Cherimoy of Peru is the fruit of *A. Cherimolia*, which is nearly allied to the preceding. The fruit is somewhat heart-shaped and scaly on the exterior, and is counted by the Creoles as being the most delicious fruit in the world, a verdict which Europeans do not confirm. The common Custard Apple, or Bullock's Heart is an eatable fruit produced by *A. reticulata*, a native of the West Indies, but cultivated in the East Indies also. Its yellowish pulp is not so much relished as that of the other kinds. In addition to their fruits, the plants of this genus are remarkable for their fragrant leaves and

romatic properties. The wood of *A. patris* is so soft and compressible that it is made use of in Jamaica in place of cork; the fruit is called the Alligator Apple as it is not eaten, as it contains a narcotic principle. [M. T. M.]

**ANONACEÆ** (*Annona*, *Anonada*, *Glyptocornea*) form an important natural order of tropical trees, remarkable for the powerfulromatic qualities of some of the species. They are nearly allied to Magnoliadæ, differing mainly in the want of stipules, and in having an albumen ruminated like a nutmeg. In most species, moreover, the stivation of the petals is valvate, so that the flowers, being formed on a ternary

axis, are usually arranged in a terminal panicle; in all there seems to be present a stimulating quality, which renders them unsafe as articles of food, or as condiments, except in small quantities. The timber of some is extremely elastic, as Lancelwood, and occasionally is intensely bitter. See CYLOPIA, UVARIA, GUATTERIA, ANONA, MONODORA, etc.

**ANONYMOS.** A name occasionally given by the older botanists to various plants which they could not readily compare with any one that had a name already.

**ANOPLANTHUS.** A genus of the Broomrape family (*Orobanchaceæ*). They are annual, leafless, parasitical herbs, growing in the roots of various plants; seldom more than one foot in height, and the whole plant of a brown or purple colour. The flower stalks are naked above and scaly below, bearing a single terminal flower; the corolla with a curved tube about an inch long, or short, and somewhat bell-shaped. There are five species known, of which *A. (Aphyllon) uniflorus*, called Cancer root, and two others, are found in North America; the remainder, which have large scarlet flowers, are natives of Asia Minor. [A. A. B.]

**ANOSMIA.** A genus of *Umbellifera*, containing a single species from Candia—a biennial, erect, herbaceous plant, with a fusiform root, obtusely trifid leaves, and white hermaphrodite flowers. It is nearly related to *Smyrniacum*, from which, however, it is separated by the want of involucre and involucre. [W. C.]

**ANOTTA, or ARNOTTO.** *Bixa Orellana*.

**ANPLECTRUM.** A genus of Melastomaceous shrubs, from the Moluccas. They have opposite, stalked, elliptic-oblong, entire, five-ribbed leaves, and flowers in axillary and terminal panicles, with four petals and eight stamens, the fruit being a subglobose berry. [J. T. S.]

**ANREDERA.** A genus of *Basellacæ*, containing a single species, a native of the West Indies and Peru. It is a climbing herbaceous plant, with alternate petiolate leaves, and pedicellate flowers, arranged in simple axillary spikes. [W. C.]

**ANSELLIA africana.** A very fine Orchid, found growing on oil-palm trees in the island of Fernando Po. It has a tall stem, not unlike a sugar-cane; broad strap-shaped leaves, and great drooping panicles of greenish flowers, blotched with purple. There is also a plant of this genus found at Natal, and called *Ansellia gigantea*; but it does not seem to be distinct from the plant of the West Coast.

**ANSERINE.** (Fr.) *Chenopodium*; also, *Potentilla anserina*.

**ANT TREE.** *Triplaris Bonplandiana*, the habitation of a species of ant (*Myrmica*).

**ANTENNARIA.** A family of herbaceous evergreen perennials, belonging to the natural order *Compositæ*, and distinguished by the dry, coloured, chaffy scales encircling each head of flowers, of which the stamens and pistils are on different plants. *A. margaritacea*, the Pearly Everlasting (*Gnaphalium* of Linneus), is a native of North America, where it grows in some districts in great profusion. It has long been a favourite garden plant in this country, and, having escaped from cultivation, has in some places thoroughly established itself as a denizen. Gathered just before their prime, the flowers retain their form and lustrous pearly hue for an indefinite period; hence they are often laid by to be added to winter bouquets, or, having been previously dyed of various colours, to be employed in decorating rooms. On the Continent, under the name of *Immortelles*, they are much used in the construction of wreaths, to be placed as votive offerings on the graves of the departed, and renewed on the anniversaries of their saints' days. *A. dioica* is a British species, not unfrequent in hilly and mountainous districts. It is a much smaller plant than the preceding, from five to six inches high, with decumbent stems, cottony leaves, and white or rose-coloured flowers. [C. A. J.]

**ANTENNARIA (bis).** The black web-like masses which hang down from the ceilings of wine vaults, and from thence cling to the casks and bottles, forming the pride of the wine-merchant, are derived from a fungus of this genus, belonging to the race of sac-bearing moulds, *Phycomycetes*. Other species creep over living leaves, covering them with a black felt, and hindering both the proper access of light and their especial functions of breathing and perspiration. The threads of which the mass is composed are either even, or swollen into joints, like necklaces, and the fruit arises from swollen portions of the threads, a miniature plant being sometimes produced within the swellings or sporangia, without distinct spores. Since many of the species are succeeded by a *Capnodium*, it is possible that the greater part are only imperfect or transitional forms of that genus. *Antennaria* are far more common in warm than in cold climates, and are the pest of orange groves and coffee plantations. They seem frequently

to accompany different species of *Coccus*, from whose exudations they probably derive their nutriment. The cellar fungus above mentioned is now referred to *Sarcidium*. [M. J. B.]

**ANTHEMIS.** The genus of plants to which the Chamomile belongs. It forms part of the Composite family, among which it may be known by its involucre, consisting of a number of overlapping scales, with membranous

row, ligulate, or strap-shaped, containing pistils only; while those of the centre, or disc, are numerous, tubular in form, and contain both stamens and pistils. The receptacle on which the flowers are placed is convex, and covered with little chaffy scales or bracts, which stand up between the florets.

The Chamomile, *A. nobilis*, is a native of Britain. Its stems are procumbent or erect, much-branched, leafy, furrowed, and hollow in the interior. The leaves are downy, pinnately divided into narrow segments. The bitterness of the Chamomile is due to a principle which possesses tonic properties. The aromatic fragrance is due to the presence of an essential oil, which is of a light blue colour when freshly extracted. Both these ingredients exist in larger quantities in the central yellow florets than in the outer white ones; hence the wild Chamomile is preferred for medicinal purposes, as in the cultivated variety the flowers are apt to become double by the conversion of the yellow tubular central florets into white strap-shaped ones like those of the ray. Owing to its stimulant tonic properties, it is much used in certain cases of weak digestion, and occasionally as an emetic, in the form of an infusion. *A. tinctoria* furnishes a yellow dye. *A. Cotula* is a common weed in the South of England, where it is called Stinking May-weed. The leaves differ from those of the true Chamomile in being quite smooth, not downy. The plant is covered with glands, which emit a powerful and disagreeable perfume, and cause swelling of the hands of persons employed to pull the plant up as a weed. [M. T. M.]

**ANTHER.** The case which contains the pollen of a plant; the terminal hollow of a stamen.

**ANTHERICUM.** An extensive genus of *Liliaceæ*, distinguished by its six-leaved, equal spreading, or campanulately connivent perianth; six hypogynous stamens with short filaments; a filiform declinate style, with an obtuse subcapitate stigma; and a three-celled ovary, containing numerous ovules. The species consist of herbs having fleshy fasciculate roots, radical filiform or linear lanceolate leaves, sometimes fleshy, often hairy, and flower scapes bearing racemes or panicles of white flowers. They are found indigenous in the middle and south of Europe, in New Holland, and in South Africa. The species are ranged in three groups, viz. —1. *Anthericum proper*, in which the perianth is

spreading, and the stamens smooth. 2. *Bulbine*, in which the perianth is spreading and the stamens are all, or each alternate one, bearded. 3. *Czakia*, in which the perianth is campanulately connivent, and the stamens smooth. 4. *Liliustrum*, which belongs to the last group, is a pretty plant with broadish grassy leaves, and a scape one and a-half foot high, bearing several largish white sweet-scented flowers, marked on each segment with a green dot. This is called St. Bruno's Lily. [T. M.]

**ANTHERIDIA** (Antherids). A term applied to the male organs in cryptogams, which, though analogous to anthers in phanerogams, cannot be considered as precisely the same organs, or, in strict botanical language, their homologues. They are of very various character and variously seated in the different sections. While amongst the higher cryptogams, in Ferns and some other allied sections, they consist of little sacs, seated on the threads or membrane immediately derived from the spores, producing bodies altogether analogous with the spermatozoon of animals; in *Selaginella*, *Ptilularia*, &c., they appear under the guise of a second smaller spore, which after a time produces the spermatozoids; and in Mosses they appear on the plant itself, once only, or more frequently, according as it is annual or perennial. In *Characeae* the antheridia are of a very complicated structure, as described under that head.

In the lower cryptogams there is no less difference in the character of the antheridia. Amongst the rose-spored and dark-spored *Algae* there are several distinct types; amongst the green-spored we have sometimes free bodies, analogous to the small spores of *Selaginella*. The spermatozoids are not, however, spiral, as in the higher cryptogams, though still endowed with active motion by means of delicate appendages. Amongst Funguses and Lichens we have again a totally different type, the spermatozoids, or spermatia as they are called, not having active motion or external motile appendages. Amongst the lower kinds it is possible that they may be merely representative, without any active functions, and in some cases, probably, they exist merely as a sort of confidia. The whole subject is, however, at the present obscure, as far as Fungi and Lichens are concerned. Organs which are sometimes called antheridia, are occasionally so denominated without any sufficient grounds, as for example the prominent cells on the gills of the hotbed toadstools, *Coprinus*. [M. J. B.]

**ANTHEROMANIA**. An unnatural development of stamens. This may take place without any detriment to the plant. As the petals are multiplied, the stamens are usually multiplied; but where the stamens are epigynous, the addition will sometimes materially disturb the normal construction of the flower. In some double flowers, the apparent multiplication of the petals is really a multiplication of the

stamens, and as such petaloid stamens are generally devoid of anthers, the fertility of the plant may in consequence be affected. [M. J. B.]

**ANTHISTIRIA**. A genus of Grasses of the tribe *Andropogoneae*. The flowers are polygamous, the hermaphrodite being sessile, or very shortly stipitate, whilst the male flowers are pedicellate. The species are all foreign, and many of them only grow spontaneously in tropical countries. One of the most interesting is the Kangaroo grass of Australia, *A. australis*, which supplies a considerable portion of food to the cattle in some parts of that country, and is consequently, valuable to the colonists. *A. arundinacea* grows from six to twelve feet high, in the East Indies, according to Roxburgh. [D. M.]

**ANTHOCARPOUS**. Composed of flowers and fruit blended into a solid mass, as in the Pine-apple.

**ANTHOCERCIS**. A genus of plants allied to *Salpiglossis*, and belonging to the same natural family *Scrophulariaceae*. The plants are shrubs, natives of the extra-tropical parts of New Holland. Some of them are cultivated in greenhouses. The calyx is five-parted, equal; the corolla bell-shaped, its tube contracted at the base, its limb five-parted; there are four perfect stamens, and a rudiment of the fifth. [M. T. M.]

**ANTHOCERIDEÆ, ANTHOCEROS**. A small natural order and genus of Liverworts, distinguished by the capsule, which is threaded by a linear columella, bursting longitudinally on one or both sides, and by the fronds being without the pores which are so conspicuous in *Marchantiaceae*. It consists of about three genera only, which occur in different parts of the world, one of which, *Carpobolus*, is remarkable for the absence of the spiral vessels or elaters in the capsule, that are so characteristic of the tribe. Two species, *Anthoceros laevis* and *A. punctatus* occur in this country on the ground, principally in the eastern counties. None of the species bear anything like the true leaves of the higher *Jungermanniæ*. [M. J. B.]

**ANTHOCHORTUS**. A genus containing a single species of *Restiacæ*, a native of the Cape of Good Hope. It is a little-known herbaceous plant with filiform leafless stems. The flowers are dioecious. The male has a six-parted infundibuliform, and purple-coloured calyx, and three stamens; the female is unknown. [W. C.]

**ANTHOXYANE**. The blue colouring matter of plants.

**ANTHODISCUS**. A genus of *Rhizophoraceae*, containing a single species, a tree from Guiana. It has alternate or opposite trifoliate leaves, and flowers in racemes, each flower having a short pedicel with two bracts. The small persistent calyx is cup-shaped, and obscurely five-lobed. The five caducous petals are concave and

coherent. The stamens are very numerous, and inserted with the petals on a hypogynous disc; they have filiform and glandular filaments, and bilocular anthers. The ovary is globose with many loculements, each containing a single ovule. There are as many oblong incurved styles as there are cells in the ovary. [W. C.]

**ANTHODIUM.** The head of flowers, or capitulum of composites.

**ANTHOGONIUM gracile.** A terrestrial Orchid from the north of India, with long, narrow, grassy leaves. The flowers form pretty complete tubes of a crimson colour, at the end of slender scapes.

**ANTHOLYSIS.** The retrograde metamorphosis of a flower: as when carpels change to stamens, stamens to petals, petals to sepals, and sepals to leaves, more or less completely.

**ANTHOLYZA.** A small genus of showy *Iridaceæ*, having a tubulose perianth, of which the limb is six-parted, unequal, the upper segment being much the longest, straight, spoon-shaped, the two lateral ones spreading and ascending, and the three lower ones very small; there are three stamens, and three stigmata, and a three-celled ovary, containing numerous ovules. They are herbs with bulb-tubers or corms, and are allied to *Gladiolus*. *A. splendens*, one of the pretty species sometimes seen in gardens, has the corms about as large as a hazel nut, a stem two to three feet high, bearing at the base, long linear or linear-ensiform strongly-nerved leaves, and terminated by a many-flowered spike of distichous flowers, the tubular portion of which is slender at the base, and triangularly gibbous about the middle, the limb being bright scarlet. The flowers appear to be long tubular, with a pair of expanded wings. *A. Cunonia*, another well-known species, has the flowers scarlet, yellow towards the base of the tube, and arranged in a second manner, instead of being distichous on the spike. There are a few other species, all South African. [T. M.]

**ANTHOPTERUS.** Under this name are comprised certain plants belonging to the order *Vacciniaceæ*. Their prominent characters are a calyx tube provided with five wings, a corolla with a tube similarly winged, and ten stamens, united together into a membranous tube. [M. T. M.]

**ANTHOPTOSIS.** Most flowers are mere temporary organs, which, when they have performed their functions, are destined to fall. In many cases, however, the flowers fall before impregnation has taken place, or shortly after, involving with them the pistil, and so inducing sterility. This may arise from various causes, as excess or want of proper moisture, but more frequently from late frosts or cold winds. The disease amongst grapes known by the name of 'couleure,' is of this description. This, however, arises frequently from poverty of sap, and may be prevented

by ringing, provided the weather be not very unfavourable. In many instances the fall of the flower naturally follows impregnation, and cannot be regarded as a disease; indeed, the time of its fall seems to depend upon the process of fertilisation, for even in cases where the flowers naturally fade very rapidly, their duration may be prolonged by preventing the access of pollen to the style. [M. J. B.]

**ANTHOXANTHINE.** The yellow colouring matter of plants.

**ANTHOXANTHUM.** A genus of Grasses of the tribe *Phalarideæ*. The few species which belong to the genus are all from temperate parts of the globe, and there is only one British, namely, the sweet-scented Vernal Grass, *A. odoratum*. It is distinguished from its allies by having membranous, awnless glumes, compressed and connate below; pales, one to each flower, bearing an awn on its back part. This grass is rather remarkable botanically, by having its flowers diandrous, i. e. with two stamens to each, three being the normal number in grasses; hence, in accordance with the Linnæan system, it is included in a different class from most of the other grasses. It forms a large proportion of many meadows and pastures, but is not considered a first-class species, having a less quantity of saccharine matter and more mucilage than some other kinds, in its composition. The peculiar odour which well-saved new hay gives out, is supposed to be principally emitted from this grass, hence the English name. [D. M.]

The fragrant resinous principle which occurs in this grass, and is called *coumarin*, is a widely-diffused natural perfume, being found, according to Professor Johnstone, in the Tonka Bean (*Dipteris odorata*), the Faham Tea-plant of the Mauritius (*Angraecum fragrans*), the common Sweet Woodruff (*Asperula odorata*), the Sweet-scented Vernal Grass (*Anthoxanthum odoratum*), the common Melilot (*Melilotus officinalis*), and the blue, or Swiss Melilot (*Melilotus caerulea*). 'It is the same odour,' he continues, 'therefore, which gives fragrance to the Tonka Bean, to the Faham Tea of the Mauritius, to our Melilot Trefoll, and to sweet-smelling hay-fields. In Switzerland the blue Melilot is mixed with particular kinds of scented cheese, and the coumarin it contains gives to that of Schabzieger its peculiar well-known odour.' The vapour of coumarin is stated to act powerfully on the brain; and it is not improbable that hay fever, to which many susceptible people are liable, may be owing to the presence of this substance in unusual quantities during the period of haymaking. [T. M.]

**ANTHRISCUS.** A genus of Umbelliferous plants, with thin, finely-divided leaves, and small, inconspicuous white flowers, arranged in umbels. Two species only are cultivated—the Chervil, *A. cerefolium*, for flavouring salads, &c., and the Parsnip Chervil, *A. bulbosus*, for its roots as a veget-

able. Chervil is an old-fashioned pot-herb, having been cultivated by Certe in his garden in Holland in 1590. It is a native of various parts of Europe, and occasionally met with in England in waste places. The young leaves, when about two inches high, are considered fit for gathering, and are then used in soups and stews, to which they impart a warm aromatic flavour. They are also used with mustard and cress in small salads, but are not much in demand in this country. The French and Dutch, however, have scarcely a soup or salad in which Chervil does not form a part; and, as a seasoning, it is by many preferred to parsley. There is a curled-leaved variety of this plant, which makes a very handsome garnish for dishes, and on this account more esteemed than the common sort. The *Cerfeuil frisé* of the French is very similar to the last, the only difference being in the leaves, which are even more frizzled than those of plants raised from seed saved in England. Care must be taken not to confound this plant with *Anthriscus vulgaris*, the common rough Chervil, which bears so great a resemblance to it as to have deceived some Dutch soldiers, who gathered it, when in England, in 1745, and put it into their soups, by which several of them were poisoned. The Parsnip Chervil, sometimes called *Cherophyllum bulbosum*, is a native of France, and, although known to gardeners since its introduction to this country in 1726, it is only within the last few years that attention has been directed to its culture as an esculent vegetable. In size and shape the root attains the dimensions of a small Dutch carrot. It is outwardly of a grey colour, but when cut the flesh is white, mealy, somewhat nutty in a raw state, and by no means unpleasant to the taste. When boiled, the flavour is intermediate between that of the chestnut and potato, in consequence of which it has been recommended for cultivation as a substitute for the latter root. [W. B. B.]

**ANTHURIUM.** A genus of plants of the Arum family, or by some referred to *Orontaceae*. The name is derived from two Greek words, signifying flower-tail, and is given in allusion to the inflorescence, which is a spike somewhat like a tail. The plants are better known under the old name of *Pothos*. They comprise several tropical plants, natives of Central or Tropical America, for the most part growing upon trees, or in their forks, and hence called *epiphytes*, in contradistinction to parasites, which not only grow upon other plants, but also derive their nourishment from them. From the root-like stems the leaves arise; these are of varied shape, in some entire, in others palmate or digitate, sometimes with swollen leaf-stalks, but in all invested below by a small sheath. The stem also gives off numerous aerial roots, like those of the common ivy, but on a larger scale. The flowers contain both stamens and pistils, enclosed within a perianth. The ovary is two to four-lobed.

The flowers thus constituted are densely packed upon a cylindrical often almost sessile spadix or spike, at the base of which is a large bract or spathe, which becomes bent backwards as the flowers come to maturity. [One of the most beautiful species, *A. Scherzerianum* of Costa Rica, has a large scarlet spathe, and a twisted spadix, which when elevated on the tall peduncle have a peculiar aspect, and have gained for the species the name of Flamingo plant. *A. ornatum*, with a white spathe and a purplish-tinted spadix, is almost equally beautiful; while some, as *A. Lindenii*, have exquisitely tinted satiny leaves]. [M. T. M.]

**ANTHYLLIS.** A genus of plants belonging to the natural order *Leguminosae*, herbaceous or shrubby, having a permanent calyx, which, after flowering, becomes inflated; petals all nearly of equal length; and a pod always hidden by the calyx, and containing one or two seeds. The only British species is *A. Vulneraria*, so called from its supposed property of staunching the blood of wounds, which virtue it probably possesses to the same extent with many other plants having equally downy leaves. Its popular name is Kidney Vetch, or Lady's Fingers, and it is frequently met with in dry pastures, especially such as are chalky, or near the sea. The leaves are rather large, of a bluish tinge, hairy, pinnate, with the terminal leaflet largest. The flowers are most commonly yellow, and grow in crowded heads, which are disposed in pairs, with large deeply-lobed bracts beneath each; the calyx is of a delicate straw colour. In some of the marine stations—especially at the Lizard, in Cornwall—the colour of the flower varies to a remarkable extent, yellow, cream-coloured, white, purple, and crimson being found all growing together. Of the shrubby species, *A. Barba-Jovis* is an evergreen shrub, a native of the South of Europe. This also has pinnate leaves and yellow flowers, and the whole plant has a silvery appearance, from which it derived its name of Jupiter's Beard and the Silver-bush. [C. A. J.]

**ANTIARIS.** The *Artocarpus* genus of plants to which the Upas-tree of Java belongs. The stamens and pistils are in separate flowers, on the same tree. The male flowers are numerous, and enclosed within a hairy involucre, formed of several fleshy divisions, rolled inwards. The calyx is in three or four pieces, and encloses an equal number of stalkless anthers. The female flower has an adherent calyx of several leaves, and is terminated by a long two-parted style. It contains a single suspended ovule, and becomes converted when ripe into a succulent drupe-like fruit. The female flowers are solitary, placed in the axils of the leaves, side by side with the heads of male flowers.

The Upas-tree, when pierced, exudes a milky juice, which contains an acrid virulent poison, called *antiarin*. Most exaggerated statements respecting this plant were circulated by a Dutch surgeon about the close of the last century. The tree

ANTIARIS & COFFEE PLANTATION IN JAVA

tract, with no other plant near it for the distance of ten or twelve miles. Criminals condemned to die were offered the chance of life if they would go to the Upas-tree and collect some of the poison. They were furnished with proper directions, and armed with due precaution, but not more than two out of every twenty ever returned. The Dutch surgeon, Foersch, states that he had derived his information from some of those who had been lucky enough to escape, albeit the ground around was strewn with the bones of their predecessors; and such was the virulence of the poison, that 'there are no fish in the waters, nor has any rat, mouse, or any other vermin been seen there; and when any birds fly so near this tree that the effluvia reaches them, they fall a sacrifice to the effects of the poison.' Out of a population of 1,600 persons, who were compelled, on

which is given off in such abundance as to be fatal to animals that approach too closely. These pestiferous valleys are connected with the numerous volcanoes in the island. The craters of some of these emit, according to Reinwardt, sulphureous vapours in such abundance as to cause the death of great numbers of tigers, birds, and insects; while the rivers and lakes are in some cases so charged with sulphuric acid, that no fish can live in them. So that doubtless the Upas-tree has had to bear the opprobrium really due to the volcanoes and their products; not that the Upas is by any means innocent, for severe effects have been felt by those who have climbed the tree for the purpose of bringing down the branches and flowers. The inner bark of the young trees, which is fabricated into a coarse garment, excites the most horrible itching. It clings to the skin, if exposed to the wet before being properly prepared. The dried juice, mixed with other ingredients, forms a most venomous poison, in which the natives dip their arrows. A view of one of these trees in the midst of coffee plantations, will be found in Plate 2.

A species of *Antiaris*, called also *Lepu-yandra saccidora*, furnishes the natives of Bombay with sacks, which are made by beating the cloth-like bark, and peeling it off from the felled branches, leaving a small portion of wood to form the bottom of the sacks. They are used to hold rice. Specimens of these may be seen in the Kew Museum. [M. T. M.]

**ANTICAL.** Placed in front of a flower, the front being regarded as the part most remote from the axis. Thus, the lip of an *Orchis* is antical.

**ANTIDAPHNE.** A genus of *Loranthaceæ*, containing a single species parasitic on the trees of the primeval forests of Peru, found chiefly on laurels. It has alternate, obovate, and entire leaves. The flowers are monœcious, arranged in small axillary spikes. The male flowers have a simple, three-lobed calyx, three stamens, with petaloid filaments, and bilocular anthers. The calyx of the female flowers is simple, with an entire margin; the ovary is unilocular, and uniovulate, with a subsessile capitate stigma. [W. O.]

**ANTIDESMA.** A genus of the natural family *Euphorbiaceæ*. Upwards of sixty species are known, all of them natives of tropical India, Africa, and Australia, and their islands. They are trees or shrubs, with alternate, simple, entire leaves, and spicate inflorescence. The flowers are inconspicuous, the males and females on the same plant. The fruit is a one-seeded drupe about the size of a pea. The bark of *A. Benitas*, which is a native of Java and the adjacent isles, affords a fibre from which ropes are made. The fruits are of a bright red colour, ripening into an intense black, with a sub-acid taste. They are used in Java for preserving, principally by Europeans, bringing about twopence per quart.

*Antiaris innoxia.*

account of civil dissensions, to reside within twelve or fourteen miles of the tree, not more than three hundred remained in less than two months. Foersch states that he conversed with some of the survivors, and proceeds to give an account of some experiments that he witnessed with the gum of this tree, these experiments consisting principally in the execution of several women, by direction of the Emperor! Now, as specimens of this tree are cultivated in botanic gardens, the tree cannot have such virulent properties as it was stated to have; moreover, it is now known to grow in woods with other trees, and birds and lizards have been observed on its branches. It occasionally grows in certain low valleys in Java, rendered unwholesome by an escape of carbonic acid gas from crevices in the ground, and

The leaves are used as a remedy against snake bites, and in syphilitic affections. The wood, when immersed in water, becomes black and as heavy as iron. All the parts of the plant have a bitter taste. The berries of *A. dumosa* are eaten in India by the natives, as well as those of *A. pubescens*, also a native of India; and its bruised leaves are used in native practice, and applied in the form of a poultice to ulcers and tumours. [A. A. B.]

**ANTIGRAMMA.** A genus of polypodiaceous Ferns of the *Asplenium* section, belonging to that series in which the sori are connivent in pairs, with the indusia opening face to face (scolopendroid). In that series it is known by having the veins of its fronds reticulated, and its sori parallel and oblique. The genus comprises a couple of Brazilian species, having simple fronds. [T. M.]

**ANTIRRHINEA.** A genus of Clinchocous plants inhabiting Mauritius and Bourbon, consisting of shrubs with leaves arranged in whorls of three. The flowers are borne on forked peduncles, and have a calyx which is short, bell-shaped, and four-toothed; and a tubular corolla, with four sessile anthers attached to its interior. The fruit is succulent externally, and contains a kernel with two one-seeded cells. The name of these plants is expressive of their valuable properties in arresting hemorrhages, and as astringents. [M. T. M.]

**ANTIRRHINUM.** A genus of *Scrophulariaceae*, containing fourteen species, natives chiefly of the Mediterranean region, though some are found in California. They are annual or perennial, rarely shrubby herbaceous plants, with the lower leaves often opposite, and the upper ones alternate. The flowers are commonly showy, and solitary in the axils of the upper leaves, or forming terminal racemes. The calyx is five-partite. The corolla has a broad tube, saccate and slightly protruding below the calyx on the lower side, but not spurred as in *Linaria*. The throat is closed by a large, projecting, bearded palate, which gives to the flower a resemblance to the face of an animal or a mask, whence the name, meaning 'snout-like.' The capsule is two-celled, oblique, and opening by two or three pores at the top. The seeds are truncate.

The genus has been divided into three sections. 1. *Orontium*, annual plants with penninerved entire leaves and compressed seeds. 2. *Antirrhinastrum*, perennial plants with penninerved entire leaves and obovate seeds. And 3. *Asarina*, with palmi-nerved lobed leaves and ovoid oblong seeds. Two species are found in Britain; the larger, *A. majus*, has probably escaped from gardens, and is found on old walls and in clefts of rocks; *A. Orontium* occurs in the corn-fields of the south of England and Ireland. [W. C.]

**ANTITROPAL.** The same as *Orthotropal*.

**ANTJAR.** The poisonous *Antiar caria*; also called *Antechar*.

**ANTROPHYUM.** A genus of polypodiaceous Ferns, belonging to the *Hemionitidæ*, distinguished by having the veins of the fronds uniform and reticulated, and the fructification, which is linear, and usually immersed in a shallow groove, also more or less, but only partially, reticulated. It is a group of very distinct aspect, though in technical characters coming close to *Hemionitis*, in which latter, however, the lines of spore-cases are more completely joined together into a network, and superficial on the frond. There are several species, all simple fronded, found in various parts of the tropics of both hemispheres. [T. M.]

**ANYCHIA.** A genus of Knotworts, *Illecebraceæ*, near to *Paronychia*, but differing in the absence of petals as well as of awns to the calyx leaves. There are two known species, both North American weeds of no beauty. The Forked Chickweed, *A. dichotoma*, is a slender herb four to ten inches high, with capillary, many-times-forked branchlets, bearing minute flowers in the forks, and opposite oblong leaves rather more than half an inch in length, accompanied with stipules like those of buckwheats (*Polygonum*). [A. A. B.]

**AOTUS.** A genus of Australian and Tasmanian shrubs, belonging to the Pea-flowered section of the *Leguminosæ* family, containing ten species. They are slender plants, with henth-like leaves, arranged in whorls round the stem, three in a whorl. The flowers are small, bright yellow, with short stalks, and the calyx is destitute of the two small bracts which are found on those of the allied genera: this gives rise to the name of the genus—*Aotus*, signifying without ears. *A. gracilima*, a native of West Australia, is a favourite greenhouse plant. It is a slender shrub, with copious yellow flowers, which are so thickly set on the stems as to hide the leaves from view. One or two other species are in cultivation, but many very pretty species have yet to be introduced. The pods of most of the species are not larger than a grain of barley, and contain each two seeds. [A. A. B.]

**APACTIS.** A Japanese tree, very imperfectly described by Thunberg, and not since recognised.

**APALANCHE VERT.** (Fr.) *Prinos verticillatus*.

**APALANTHE.** A generic name given by Planchon to a few species of *Anacharis*, separated from that genus because of their having hermaphrodite flowers. It has, however, been found that one of these species, *A. Schweinfurtti*, is the same as *Anacharis Alsinistrum*, which, although its flowers are generally dioecious, is yet said to bear fertile flowers with three to six stamens, sometimes merely short sterile filaments without anthers or with imperfect ones, and sometimes with oblong

almost sessile anthers. It is probable that, when the other species are more carefully examined, no foundation will be found for the same assertion. See *Anacharis*. [W. C.]

**APARGIA.** This name is used in some English books for one or two species of Hawkbit, *Leontodon*, called *A. Heyda* and *A. autumnalis*, the latter of which is sometimes referred to *Oporina*. [T. M.]

**APATURIA.** Terrestrial leafless Orchids, from the continent of India, Ceylon, and China. They are of no interest, their pallid flowers hanging down from the side of a rather long spike. One of the marks by which they are most easily known is having, along with a structure similar to that of *Bletia*, scales covered by thin membranous scales.

**APEIBA.** A genus of the Lime-tree family, *Tiliaceæ*, containing twelve species. They are trees or shrubs with alternate, stalked, entire or serrate leaves, which are covered on both surfaces with starry pubescence, and have at the base of their footstalk two stipules, which fall early. The peduncles are terminal and opposite the leaves, much branched and many-flowered; the flowers yellow or greenish, and interspersed with bracts. Their fruits are woody, roundish, and often covered with tubercles, or stiff prickles. The species are found in Mexico, the West Indies, and Southern tropical America. The fibrous bark of *A. Petrus* is known in Panama as Cortega, and is used for making cordage, being strong, tough, and distinguished from other indigenous fibres by its whiteness. The wood of *A. Tibourou* being light and soft, is used in Brazil for making the raft-boats called jangadas. Its fruit, in size and appearance, is much like that of the Spanish chestnut. *A. aspera* has a flattened circular fruit, with rough points, resembling the cup of an acorn, only closed at the top. [A. A. B.]

**APERA.** A genus of Grasses of the tribe *Agrostideæ*. As defined by Adanson and Beauvois, a few species only are referable to this genus, which in more modern works will be found described under the genera *Agrostis*, *Muhlenbergia*, and *Vulpia*. The principal characters depended on to separate it from *Agrostis* are the lower glume being smaller than the upper, and the presence of a rudimentary second floret, beside the perfect floret. The British species, *Apera Spica-cens*, Wind-Bent Grass, is one of the prettiest of English grasses, the light feathery panicles of inflorescence, with the long awns attached to the glumes, seldom failing to attract attention from even those who are little in the habit of observing plants. Although of small importance as an agricultural species, it is valued for the beauty of its flowers, which remain long on the rachis, and form a handsome drawing-room ornament, even in their natural state, but particularly so when dyed crimson, green, or any other bright colour. [D. M.]

**APETALON.** A minute leafless Orchid, found beneath the shade of Bamboos in Coorg.

**APETALOUS.** Having no petals. Also extended to plants that have neither calyx nor corolla.

**APHANES.** A synonym of *Alchemilla arvensis*.

**APHANOSTEPHUS.** A genus of the Composite family, numbering three species, which are found in Texas and New Mexico. They are related on the one hand to the daisy (*Bellis*), from which they differ in the presence of a pappus to the achenes, and on the other to the Australian genus *Brachycome*, from which the rounded and striate, instead of flattened, achenes at once distinguish them. They are much-branched annual plants, six inches to a foot high, having linear or spatulate, toothed or entire, more or less hoary leaves, and slender twigs, terminating in a single stalked flower-head about half an inch across, the rays pink or white, the disc yellow. *A. ramosissimus*—called also *Egletes ramosissima*—is quite a pretty plant in cultivation, producing a great abundance of flower-heads, with white rays, tinged with pink. [A. A. B.]

**APHELANDRA.** This name is applied in consequence of the flowers of the plants of this genus having one-celled anthers. They are small shrubs, natives of tropical America. The inflorescence consists of four-sided spikes, with slightly membranous bracts, handsome reddish or scarlet flowers, with a gaping two-lipped corolla, the lower lip divided into three lobes, the central one of which is much larger than the lateral ones; the stamens are four in number, one pair longer than the other (didynamous), the anthers one-celled; the capsule is sessile roundish, two-celled, each cell containing two compressed seeds. *A. cristata* is a remarkably handsome stove plant, with fine ovate pointed leaves, and showy spikes of blossom. It was formerly referred to the genus *Justicia*, and belongs to the order *Acanthaceæ*. *A. aurantiaca* is scarcely less handsome than the other. [M. T. M.]

**APHELEXIS.** A genus of Madagascar plants, belonging to the Composite family (*Compositæ*), having much resemblance to the everlasting flowers (*Helichrysum*), and differing from these chiefly in the hairs of the pappus. Five species are known, all of them having very small leaves, which are closely pressed to the stem, like those of the club-moss. The flower-heads are either large, solitary, and of a pink colour, or small, yellow, and two or three together at the ends of the branches. The plants known in gardens as *Aphelaxis*, and so commonly cultivated in greenhouses, are natives of the Cape, not of Madagascar, and are generally placed in the genus *Helipterum*. [A. A. B.]

**APHELIA.** A genus of *Desfontainiaceæ*,

consisting of a small sedge-like plant, *A. cyperoides*, from the southern shores of New Holland, which grows in small tufts, with short thread-like leaves and naked stems, a few inches high, at the top of which are short two-ranked spikes of glumaceous flowers, the lower glumes frequently empty; the outer glume of each flower is much acuminate, the upper glume shorter, hispid at the base. [J. T. S.]

**APHLOIA.** A genus of the *Flacourtiaceae* family, containing but few species. They are small trees, with much-cut, serrated or entire alternate leaves, and axillary, solitary or fascicled flowers, without petals. From all the allied genera, they are distinguished by their single one-sided placental line, to which the ovules are attached. They are natives of Madagascar or the Mauritius, some of them varying much in their foliage, entire or pinnatifid leaves being found on the same plant. *A. theiformis* has an emetic bark. [A. A. B.]

**APHYLLE.** A name applied to that portion of cryptogamic plants comprehended under the term Thallophytes, in consequence of the greater part of them being destitute of such modifications of leaves as occur in mosses, ferns, &c. Some seaweeds, or *Algæ*, indeed, have leaf-like organs, but these differ in many respects from leaves, and are mere expansions of the common stem. [M. J. B.]

**APHYLLANTHES.** A genus of *Liliaceae*, consisting of a single species, found in the South of Europe. It is a perennial, slender, rush-like herb, leafless, the scapes having membranous sheaths at the base, like those of the rush, and being terminated by a small head of fugacious blue flowers. The perianth is six-parted, spreading at the apex, connivent into a short tube at the base; six stamens, with thread-like filaments, are inserted above the base of the perianth; the filiform style is terminated by a three-lobed stigma; and the ovary is three-celled, with a solitary basal ovule in each cell. The scapes appear like grassy leaves, but are seen to be tipped by the glumaceous scales which protect the blossom-buds. [T. M.]

**APIACEÆ** (*Umbelliferae*, *Umbelliferae*). Under this name is collected a very large number of plants inhabiting for the most part, in the northern regions of the northern hemisphere, woods, bogs, marshes, and dry places. As we approach the equator they become less and less known, and in the southern hemisphere, are comparatively rare. They all have a double-didymous—inferior ovary, separating when ripe into two similar parts, vulgarly called seeds, surmounted by a superior calyx, which is generally scarcely, and often not at all observable; five separate petals; five intervening epigynous stamens; and two styles proceeding from what is not very rarely a double epigynous disk. Parsley, Fennel, and Caraway are in this order. Although the order

numbers at least 1,500 species, divided among nearly 300 genera, not a tree is known among them; a very few only attaining the condition of woody bushes. Many are important as producing articles of food; many are poisons; most are merely unimportant weeds; a few, like *Astrantia*, are furnished with gay colours, and thus become objects of decoration. One of them, *Bolax Gleboria*, forms huge tussocks in the Falkland Islands, resembling haycocks. Of the harmless species, in which, with a little aroma, there is no considerable quantity of acrid watery matter or gum-resinous secretion, must be more particularly named Celery, Fennel, Samphire, Parsley, and the roots of the Carrot, Parsnip, and Skirret (*Sium* *Seasorum*). The root of *Eryngium campestre* and *maritimum*, vulgarly called Eryngo, is sweet, aromatic, and tonic. The aromatic roots of *Meum athamanticum* and *Mutellina* form an ingredient in Venice treacle. Angelica root, belonging to *Archangelica officinalis*, is fragrant, sweet when first tasted, but leaving a glowing heat in the mouth. Others are gum-resinous, as the species of *Ferula*, yielding *Asafoetida*, the fetid odour of which is supposed to be owing to sulphur in combination with a peculiar essential oil. For aromatic and carminative fruits, the most celebrated are Anise (*Fimbricella Anisum*), Dill (*Anethum graveolens*), Caraway (*Cuminum Carui*), and Coriander (*Coriandrum sativum*). Besides these, great numbers of less note are also employed for the same reason, the chief of which are the Ajwains or ajowains of India (species of *Psychotria*), Honewort (*Oenanthe Anomum*), whose fruits smell of bugs, and Cummin (*Cuminum Cyminum*), now only used in veterinary practice. Among poisons, Hemlock (*Conium maculatum*) holds the first place. *Anthriscus vulgaris* and *Sylvestris* are not so dangerous. *Ethusa Cymaphum*, *Oenanthe crocata*, *Ch. Phellodrium*, *Cicuta maculata*, and *C. virosa* are other fatal species. See Plate 16.

**APICRA.** A division of the genus *Aloe*, sometimes regarded as distinct, and comprising, along with *Haworthia*, a group of species of very different aspect from the great cylindrical or tubular-flowered aloes more commonly associated with the name. The present are dwarf or acaulescent plants, with very crowded leaves and slender flower-scapes, bearing erect greenish-white flowers, which consist in the *Apicra* series of a regular cylindrical perianth, having short, spreading, conformable limb segments. A considerable group of species is referred hither. [T. M.]

**APICULATE.** Terminating abruptly in a little point.

**APIOS.** A leguminous genus of three species, *A. suberosa* being a climbing plant, having pinnate leaves, with a terminal leaflet, and lateral clusters of brownish-purple sweet-scented flowers. It is a native of North America, from Pennsylvania to Carolina, on the mountains, in hedges, and among

bushes. In this country it grows freely in common garden soil, and is easily increased by tubers. It requires to be supported like peas. The tubers, though small, are numerous, farinaceous, and eatable. [C. A. J.]

**APIOSPERMUM.** A genus of *Pistia*ceae, containing a single species, a native of the marshes of Cuba. The genus has been separated from *Pistia*, with which it agrees, except that its spadix is continued beyond the whorl of stamens, and its seeds are smooth. [W. C.]

**APIUM.** A genus of Umbelliferous plants consisting of but few species, one of which is the well-known Celery, *A. graveolens*; and the other the common Parsley, *A. Petroselinum*, which occupies a spot in almost every garden.

The Celery, in its wild state, is found in marshy places and ditches near the sea coast in various parts of England. It is a biennial; and as grown in its native ditches the whole plant has a strong taste and smell, and is acrid and dangerous to eat. Such, however, are the wonderful changes effected by cultivation, that this rank, coarse, and more than suspicious plant has by degrees been transformed into the sweet, crisp, wholesome, and most agreeable of our cultivated vegetables. In Italy and the Levant, where it is much grown, but not blanched, the green leaves and stalks are used as an ingredient in soups. In this country they are always blanched and used raw as a salad, or dressed as a dinner vegetable. They are also sometimes made into an agreeable conserve. There are two kinds of Celery; the red and white-stalked, of both of which there are many sub-varieties. The seeds, when bruised and tied into a bag, form an excellent substitute for flavouring soups when Celery cannot be procured.

Celeriac or Turnip-rooted Celery, is a variety of the preceding, obtained by cultivation. It is very seldom grown in this country; but in France, and more especially in Germany, it is commonly employed as a vegetable, and is considered harder than Celery, and capable of being preserved for use much later in spring. It is excellent for soups, in which slices of it are used as ingredients, and readily impart their flavour. With the Germans it is also a favourite salad: the roots being prepared by boiling until a fork will pass readily through them, and when cold eaten with oil and vinegar.

Parsley, which is sometimes called *Petroselinum sativum*, is a hardy biennial plant; and although so common as to be naturalised in some parts of England and Scotland, was originally introduced from Sardinia, of which it is a native, in 1846. It is a well-known seasoning herb, and is in constant demand throughout the year for a variety of culinary purposes, such as sauces, soups, &c., and for garnishing various dishes. Among the ancient Greeks and Romans, Parsley always formed a part of their festive garlands, on account of retaining its colour so long; and Pliny

states that in his time there was not a salad or sauce presented at table without it. The ancients supposed that its grateful smell absorbed the inebriating fumes of wine, and by that means prevented intoxication; but however this may be, we believe nothing is more effectual than the eating a leaf or two of Parsley to take off the smell and prevent the after-taste of any dish that has been strongly flavoured with onions. In Cornwall it is much esteemed and largely used in *parsley pie*, which are peculiar to that part of England. If dried and preserved in bottles from which the air is excluded, it will retain its flavour for a long time, and be found extremely useful for seasoning omelets and similar dishes. The curled-leaved Parsley is always preferred for use as being more ornamental than the common sort, of which it is nothing more than a variety obtained and continued by careful cultivation.

Hamburgh Parsley, *A. Petroselinum var. fastiformis*, is a variety of the preceding, and may be used for the same purposes; but it is chiefly grown for the sake of its long spindle-shaped roots, which are dressed and served at table as a separate dish like those of the parsnip. [W. B. B.]

*Petroselinum* has been distinguished from *Apium* by each part of the fruit having four narrow ribs, with one oil-vessel (vitia) in each furrow, and two on the commissure or line of junction, the albumen being plano-convex, while in *Apium* the latter is terete. Benthams and Hooker make it a section of *Cerium*, distinguished by its obsolete calyx teeth and smooth ovate fruit, the common Parsley being by them named *Cerium Petroselinum*.

**APLECTRUM** *Agave* is the name of a remarkable terrestrial Orchidaceous plant, which bears in the United States the names of Putty-root and Adam-and-Eve; it is allied to the genus *Cynallorsea*, and is found, though rarely, inhabiting woods, growing in rich mould. It forms tubers an inch in diameter, and scapes a foot high, bearing a few dingy green flowers. Owing to its tubers containing a large quantity of very adhesive mucus, which is employed in mending broken porcelain, it has gained in the United States the name of Putty-root. The solitary leaf is broad and ribbed, like that of a *V-*

**AFLOCARYA.** A genus of South American scrubby shrubs, of the order *Nolaneae*, with fleshy leaves, separated from *Nolans* on account of the five ovaries being free, and the fruit of five separate nuts. [J. T. S.]

**AFLOPHYLLUM.** The plants constituting this genus of the *Rue* family (*Asteraceae*) are perennials or small shrubs, with simple, alternate, dotted leaves, no stipules, and bearing yellow or white flowers in panicle cymes. They are distinguished from *Rue* (*Aster*) by the simple, undivided leaves, whence also they derive their name, as well as by the parts of the flower being arranged in fives, not in fours. They are natives of S. Europe, &c. [M. T. M.]

**APIOTAXIN.** A genus of the Compo-

site family (*Compositæ*), chiefly found in the alpine and temperate regions of the Himalayas, one only being known in Siberia. Upwards of twenty species are recorded. They are herbs from one inch to three feet in height, varying much in appearance, those growing in the high alpine regions being very dwarf, the taller species being found at much lower elevations, and some of them not unlike burdocks, but the scales of their involucre are not hooked, as in that genus. The hairs of the pappus being in a single series, give rise to the name of the genus. *A. goessypina* is found in Kumaon, at an elevation of from 16,000 to 18,000 feet. The plant, altogether not higher than two or four inches, has its leaves densely clothed with long cottony hairs, which form an admirable covering to protect it from the cold to which it is exposed. *A. Lappa*, the root of which is the *Costus* of the ancients, is found on the mountain slopes of the Cashmere Valley, at an altitude of 8,000 to 9,000 feet. It is a procreant herb, six to seven feet high, with an annual stem and perennial root, which is thick and aromatic; the leaves lyrate-pinnatifid, and about two feet long; the flower-heads two to three, sessile, and the florets of a purple colour. Dr. Falconer (from whose account the following is abridged) described the plant under the name of *Aucklandia Costus*. In Cashmere the plant is called Koot, in Bengal Putchuk, and the Arabic name is Kooat. It is gathered largely, the greater portion being laden on bullocks, sent through the Punjab to Bombay, and there shipped for the Red Sea, the Persian Gulf, and China. A portion of it finds its way to Calcutta, through Hindostan. The roots are dug up in September and October, cut into pieces, two to six inches long, and exported without further preparation. The quantity collected amounts to about 200,000 lbs. per annum; the cost of collecting and transport to a mercantile depot in Cashmere is said to be 2s. 4d. per cwt., but when it reaches Canton it is sold for 47s. 5d. per cwt. The root is used by the Chinese as an aphrodisiac, and for burning as incense in their temples. In Cashmere the root is only employed for protecting bales of shawls from the attacks of moths; and the stems of the plants are suspended from the necks of children, to avert the evil eye. [A. A. B.]

**APOCARPOUS.** Having the carpels, or at least their styles, disunited.

**APOCYN GÖBE-MOUCHE.** Fr. *Apocynum androsaemifolium*.

**APOCYNACEÆ.** (*Contorta*, *Vincæ*, *Apocynæ*, *Dogbanes*.) A natural order of corolliferous Exogens, with a superior ovary, free epipetalous stamens, a pulley-shaped (trochlear) stigma, and unequal-sided lobes of the corolla, on which last account Linnaeus called them contorted, or twisted-flowered plants, the corolla having some resemblance to a Catharine-wheel firework in motion. Most of the species inhabit tropical countries; the northern forms are

the *Vincæ*, or Periwinkle, *Nerium*, or Oleander, and a few more. In general the species form a poisonous, acrid, milky secretion, which renders them dangerous; but others are mild enough in their action to be useful in medicine, and in a few cases the milk is bland enough to form a palatable beverage. Some yield the gum-elastic (caoutchouc (see VAHEA)); while some *Hancornias* and *Carissas* produce an eatable, and, as travellers say, a pleasant fruit. See TANGHINIA, TABERNÆMONTANA, HANCONIA, &c. The commoner forms in cultivation are those of *Allamanda*, *Parsonia*, *Vinca*, and *Tabernaemontana*. About 600 species are known, distributed through about 100 genera.

**APOCYNUM.** A genus of *Apocynaceæ*, containing four species of perennial herbs, with upright branching stems, opposite, mucronate-pointed leaves, a tough fibrous bark, and small, pale, and terminal or axillary flowers on short pedicels. The calyx is five-parted, and the corolla campanulate, five-cleft, bearing five triangular scales in the throat opposite the lobes. The five stamens, inserted on the very base of the corolla, have the filaments flat and shorter than the arrow-shaped anthers, which converge around the ovoid obscurely two-lobed stigma, and slightly adhere to it by their inner face. The fruit consists of two long, slender and coriaceous follicles, containing numerous ovoid seeds, comose with a long tuft of silky down at the apex. From the fibrous bark of *A. cannabinum* (commonly called Indian Hemp), and *hypericifolium*, the Indians prepare a substitute for hemp, of which they make twine, bags, fishing-nets, and lines, as well as linen for their own use. The members of the genus afford by incision a milky juice, which, when sufficiently dried, exhibits the properties of India-rubber.

*A. androsaemifolium*, the Fly Trap of North America, is cultivated as an object of curiosity in this country. The five scales in the throat of the corolla of this plant secrete a sweet liquid, which attracts flies and other insects to settle on them; the scales are endowed with a peculiar irritability, the cause of which has not been accurately determined, but which causes them to bend inwards towards the centre of the flower, when touched, and to retain the unlucky flies as prisoners. Numbers of dead flies may be seen in the several flowers of this plant: the movement of the scales probably serves to scatter the pollen on the stigma. These plants are more or less poisonous and acrid, and produce emetic and diaphoretic effects. They are widely distributed over the temperate parts of both hemispheres, and a few are in cultivation, but possess no great beauty. [M. T. M.]

**APODANTHES.** One of the genera of *Rafflesiaceæ*, characterised by unisexual flowers, a four-cleft calyx, which is provided with two bracts, petals inserted

VEGETATION OF TENERIFE: VIEW IN THE CALDERA  
(After Webb)

a. *Pistacia atlantica* b. *Juniperus cedrus* c. *Phoenix dactylifera*  
d. *Laurus indica* e. *Pinus canariensis*

on the ovar; . The male flowers are not known; the female flowers have a half-superior ovary which, when mature, becomes a fleshy fruit with a four-cornered cavity, containing several seeds with a hard-pitted covering. The plants are natives of Zulana. [M. T. M.]

**APODYTES.** A genus of *Oleaceæ*, containing a single species from Port Natal, South Africa. It is a tree or shrub, with alternate, exstipulate, petiolate, and entire leaves. The flowers are in loosely-branched terminal racemes. The calyx is small, five-toothed, and persistent. The corolla consists of five oblong linear petals, rising from the receptacle. The stamens are five in number, alternating with the petals, and by thin dilated filaments, uniting the petals together through two-thirds of their length. The ovary is free and unilocular, with two ovules. The style is excentric, and knotted at the base; the stigma is minute. The fruit is a drupe, one-celled, and one-seeded by abortion, of a peculiar kidney shape, with a fleshy protuberance from the hollow side. [W. C.]

**APONOGETON.** A genus of aquatic plants belonging to the *Juncaginaceæ*, and remarkable for producing its flowers in conjugate or binate spikes at the ends of the flower scapes. The flowers consist of several (six to eighteen) stamens with subulate filaments, and are destitute of both calyx and corolla, the conspicuous part of the inflorescence being a double row of large white bracts, at the base of which the minute apetalous flowers are seated. *A. distachyon*, a very handsome, deliciously fragrant water-plant, a great favourite in gardens, has been well figured and described from vigorous, well-developed specimens in *Paxson's Flower Garden* (il. t. 43) by Dr. Lindley, who writes:—'In appearance it resembles a Pondweed (*Potamogeton natans*), except that it is of a clear green colour without any tinge of brown. Its bulb or corm is described as being as large as a hen's egg. The leaves float on the surface of the water, are oblong, about eighteen inches long when full grown, flat, and have three distinct veins running parallel with the main rib. When young their sides are rolled inwards. The flowers are placed on a forked inflorescence, originally included within a taper-pointed calyptrate spathe (cap), which is forced off as they advance in size. When fully formed each fork of the inflorescence is very pale green, and is bordered by two rows of large, ovate-oblong, obtuse, ivory-white bracts, in the axils of which stand the minute flowers. The latter are bisexual, and destitute of both calyx and corolla. Twelve hypogynous free stamens, with dark purple anthers, surround from four to six distinct carpels, each of which has a short curved style, a bimple minute stigma, and six erect anatropal ovules. After flowering the bracts and inflorescence grow rapidly, acquire a deep green colour, and soon resemble tufts of leaves, among which lie in abundance large membranous

indehiscent beaked carpels, containing about four seeds each, and readily tearing at the sides.' This species is common at the Cape of Good Hope, where it bears the name of Water Uintjes. The flowering tops are, according to Mr. Bunbury, sometimes used in the colony both as a pickle and as a substitute for asparagus. Martyn states that the 'bulbs' are eaten roasted. There are one or two other species from South Africa. The Indian *A. monodachys* is now referred to *Spathum*. [T. M.]

#### APOO. (Fr.) *Urtica*.

**APOPHYSIS.** A name given to a swelling, often hollow, or of extremely loose texture, at the base of the capsules in several mosses. It is developed extremely in the natural order *Splachnæ*, where it often exceeds in size the true capsule. It attains its maximum in *Splachnum luteum* and *rubrum*, where it is a most conspicuous object, hanging down like an umbrella or the vesicle of *Acophora*. In *Odipodum* almost the whole of the stem consists of apophysis, which is confluent at once with it and the capsule. [M. J. B.]

**APOROCACTUS.** A genus of *Cactaceæ*, distinguished from *Cereus* by the elongated narrow tube of the perianth, and its obliquely gaping, somewhat two-lipped limb, and also by the graduated insertion of the fewer stamens, all of which are exerted, and the upper ones longer than the rest. It includes a few species known in gardens under the name of *Cereus*. *A. Baumanni*, sometimes called *Cereus Tweedii*, is a handsome, cylindricaceous, erect-stemmed succulent plant from Buenos Ayres, having a many-angled stem, and numerous rich orange-crimson, slender-tubed flowers, curving at the base so as to be inserted obliquely, and also curving in an opposite direction at the mouth, which is silently spreading. *A. flagelliformis*, the *Cereus flagelliformis* or Creeping *Cereus* of gardens, is a well-known plant, with long, slender, pendent stems, producing a profusion of narrow rose-coloured flowers. It is a native of Peru. [T. M.]

#### APOROSA. *Serpa*.

**APORUM.** A division of the great genus *Dendrobium*, distinguished by having fleshy equitant leaves. The flowers are small, and have no beauty.

**APOSTASIA.** Among the forests of Malacca, Borneo, and Assam are found two species of Endogens, with low stems, covered with grassy leaves, and terminal panicles of small yellow flowers, which throw an unexpected light upon the structure of the allied order of orchids. The calyx and corolla consist each of three narrow equal pieces. The anthers—two or three—are distinct; the style is perfectly free from the stamens, and the ovary is three-celled; so that the gynandrous structure of orchids wholly disappears. Another genus nearly related is *Neowiedia*, a Borneo

plant resembling a dwarf palm, with dense spikes of triandrous flowers, and a three-winged ovary, terminating in a narrow neck. They represent the *Apostasiaceæ*.

**APOSTASIACEÆ.** This is a very small group, bordering on the limits of the vast Orchidaceous order, from which it differs mainly in its stamens not being gynandrous, but distinct from each other and from the style. It stands near the genus *Oypripedium*, some of the reputed species of which, now called *Selenipedium*, have a three-lobed ovary. The flowers of all the known species are small and inconspicuous, while the leaves are strongly marked by stout parallel larger veins, as in *Curculigo*, or any similar plant.

**APOSTAXIS.** Unusual discharge of the juices of plants. This may arise merely from an extreme abundance of fluid, which is in consequence discharged, as in Indian Shot or the Vine, from the point, or serrated top of the leaves. If, however, it is elaborated sap which flows out, either from injury or weakness of the tissues, the effect may be injurious. And this is exactly the case in what is called gumming; a condition which may be induced artificially, by allowing water to drop constantly over a branch. This always proceeds from injured or diseased tissues, and is with difficulty arrested when once set up, and, if so, is the certain forerunner of fatal canker. In some cases, as in the Trageacanth plant, the gum is organised, and is derived apparently from the medullary rays. In Conifers, a flow of resin is often attended with the same fatal results as gumming in Plums and other allied plants. In this case it seems to arise generally from root-confinement and a consequent check of circulation. [M. J. E.]

**APOTHECIA.** The shields of lichens; firm horny disks arising from a thallus, &c., containing spores.

**APPENDAGES.** Leaves and all their modifications are appendages of the axis. Hairs, prickles, &c., are appendages of the part which bears them. A name applied to processes of any kind.

**APPENDICULA.** A genus of inconspicuous Orchids, inhabiting tropical Asia. They have long stems clothed with oblong distichous leaves, bearing at the end a few green flowers. About twenty species are known, one only of which has been in cultivation in Europe.

**APPETIT.** (Fr.) *Allium Schenoprasum*.

**APPLE.** *Pyrus Malus*. — **ADAM'S.** A variety of the Lime, *Citrus Limetta*. — **ALLIGATOR.** The fruit of *Anona palustris*. — **BALSAM.** The fruit of *Momordica Balsamina*. — **CHERRY.** The Siberian Crab, *Pyrus baccata*. — **CUSTARD.** The fruit of *Anona reticulata*; also a common name for the family of *Anona*. — **DEVIL'S.** The fruit of *Mandragora officinalis*. — **EGG.** The fruit of *Solanum*. — **ELEPHANT.**

The fruit of *Persea elephantum*. — **KANGAROO.** The fruit of *Solanum laciniatum*. — **KAU' or KEL.** The South African name of an edible fruit produced by *Aberia Kaffra*. — **LOVE.** The fruit of *Lycopersicon esculentum*. — **MAD, or JEW'S.** The fruit of *Solanum esculentum*. — **MAMMEE.** The fruit of *Mammea americana*. — **MANDRAKE.** The fruit of *Mandragora officinalis*. — **MAY.** *Podophyllum peltatum*. — **MONKEY.** A West Indian name for *Clusia flava*. — **OAK.** A spongy excrescence, formed on the branches of the oak-tree. — **of FERU.** The fruit of *Nicandra physaloides*. — **of SODOM.** The fruit of *Solanum sodomium*. — **OTAHEITE.** The fruit of *Spondias dulcis*. — **PERSIAN.** A name given to the Peach, when first introduced into Europe. — **PINE.** *Ananassa sativa*. — **RAIRIE.** *Peoralea esculenta*. — **ROSE.** The fruit of *Eugenia malaccensis*, *E. aqua*, *E. Jambos*, and others. — **STAR.** The fruit of *Chrysophyllum Cainito*. — **THORN.** *Datura Stramonium*. — **WILD BALSAM.** *Echinocystis lobata*.

**APPLE BERRY.** A colonial name for *Billardiera*.

**APPLE-TREE, MALAY.** *Eugenia malaccensis*.

**APPLEWORTS.** An English name proposed for the order *Pomaceæ*.

**APRICOT.** *Prunus Armeniaca*; formerly sometimes written *Apricock*. — **WILD.** *Mammea americana*.

**APTANDRACEÆ.** Out of the genus *Aptandra*, Mr. Miers has proposed to form a natural order, bearing this name. Only one species is known, a tree with alternate leaves and minute flowers, a native of the banks of the river Amazon. It is usually referred to *Humirada*. Its great feature is having anthers opening by reflexed valves, as in *Lauraceæ*.

**APTERIA setacea.** An obscure North American plant related to *Burmammia*, but destitute of wings to the fruit.

**AQUIFOLIACEÆ (Hicinea, Hollyworts).** The common Holly-tree is the type of a small natural order of shrubs and trees, with rotate monopetalous flowers, a definite number of epipetalous stamens, and a fleshy fruit. The species may be said to possess in general emetic qualities, variously modified in various instances. Birdlime is obtained from the bark of the common Holly, and the beautiful white wood is much esteemed by cabinet-makers for inlaying. A decoction of *Ilex vomitoria*, called Black drink, is used by the Creek Indians at the opening of their councils, and it acts as a mild emetic. But the most celebrated product of the order is Maté, or Paraguay tea, the dried leaves of *Ilex paraguayensis*: which see.

**AQUILARIA.** The Eagle-wood, or *Agallochum* of the ancients, is produced from certain species of this genus: hence the

name. The genus gives its name to the order *Aquillariaceae*, and is characterized by a top-shaped leathery calyx, downy externally, whose limb is divided into five small oblong, reflexed segments; from the throat of the calyx project ten woolly scales, which adhere to the whole length of the interior of the calyx tube, and alternate with the ten stamens, the filaments of which also adhere for nearly their whole length to the calyx tube, and are attached to the back of the anthers below their middle. The ovary is two-celled, each cell containing a single ovule, suspended from the placenta; these ovules are flat on one side, convex on the other, and winged, the wing being prolonged downwards into a horn-like process; the ovary is surmounted by a short style, terminated by a large round stigma, which is depressed in the centre. *A. Agallocha*, a large tree, inhabiting Sikkim, and provided with alternate lance-shaped stalked leaves, furnishes an odoriferous wood, called Aloes-wood, or Eagle-wood, supposed to be the Aloes-wood of Scripture. The wood contains an abundance of resin, and an essential oil, which is separated, and highly esteemed as a perfume. The Orientals burn it in their temples for the sake of its slight fragrance, on which account also it was used in the palace of Napoleon the First. It has been prescribed in rheumatic affections in Europe. Other but inferior kinds of this wood are said to be furnished by species of *Alseojium* and *Eccocaria*. [M. T. M.]

**AQUILARIACEÆ** (*Aquillariads*) consist of fragrant tropical Asiatic trees, with small apetalous flowers, resembling those of a *Rhamnus*. Only ten species are known, of which the most important is the genus *AQUILARIA*: which see.

**AQUILEGIA**. A genus of *Ranunculaceae*, widely distributed over the temperate regions of the northern hemisphere. It is generally considered to consist of many species, but the authors of the *Flora Indica* believe that the greater number of these are merely varieties. It is distinguished by the curious structure of the flowers, which have five flat, elliptical coloured sepals, alternating with as many spurred petals; the spurs are very large, and produced backwards into hollow tubes, like a cornucopia with the mouth downward, and are frequently curved round towards the central axis of the flower at the extremity. The fruit consists of five follicles, with numerous seeds. In cultivation, double varieties occur, which have a series of spurred petals, with the spurs included in those of the exterior ones, like a nest of crucibles. Stellate varieties also occur, which have the petals flat, and destitute of

leaves twice or thrice-ternate. *A. vulgaris*, the Common Columbine, is apparently native in Britain. It has the flowers usually purplish blue, but in cultivation they vary much, being dark purple, dull reddish, or white. *A. alpina* has much larger flowers and shorter spurs, and stamens hardly exceeding the petals. *A. canadensis* has scarlet and yellow flowers, with very long slender straight spurs, and very long stamens. The species are quite hardy in the open border. [J. T. S.]

#### ARABETTE. (Fr.) *Arabis*.

**ARABIS**. An extensive genus of annual or perennial herbaceous plants, belonging to the natural order *Cruciferae*, and bearing white, or (rarely) purple flowers. For the most part they are under a foot in height, the root-leaves are stalked, but the upper ones clasp the stem, and all are more or less thickly set with forked hairs. They inhabit various countries, but the British species possess little interest. The name *Arabis* was probably given to the genus because most of the species delight in stony or sandy soil, such as that of *Arabis* is presumed to be: Wall-cress, the English name, has similar reference to the usual place of growth. Many species are well adapted for rock-work, and others are equally fitted to be grown as border flowers, as they bloom earlier than most garden plants. The genus being closely allied with others, some confusion exists as to the names severally assigned to the plants which it contains. Some species are described under the names of *Turritis* and *Cardamine*. [C. A. J.]

**ARAÇA**. A name given to the fruit of some Brazilian *Eugenia*s.

**ARACEÆ** (*Aroides*, *Arads*) are incomplete plants of the Endogenous class, with numerous naked unisexual flowers, closely packed upon a spadix, shielded when young by the hooded leaf called a spathe, as is seen in the common Wake-robin (*Arum maculatum*). They are common in tropical countries, but rare in those with a cold or temperate climate. Botanists have mixed them with *Orontids*, from which their hermaphrodite flowers distinguish them. Most have tubercous roots (corms), but some acquire the stature of little trees, the most interesting of which is the Dumb-cane, a species of the genus *Dioscorea*. The acrid poisonous qualities which have given rise to the latter name are characteristic of the order. Nevertheless the whole contain starch in such abundance that it may be separated in the form of arrowroot or used as food in its combined state; only, however, after careful washing to remove the acrid juices. Thus, the common spotted *Arum* was eaten with us in time of scarcity, and yields a kind of arrowroot, and the *Colocassias* are grown everywhere in hot countries as common field crops. See all these names. One of the peculiarities of the order is to extend the end of the spadix into a soft, cellular,

exception. The five-spurred petals with incurved heads have been compared to five doves, the sepals representing the wings, and to this the English name Columbine refers. The leaves are ternate, the root-

enlarged process, which is the growing point of the flower-branch, and analogous to the succulent receptacle of the strawberry, the dry core of the raspberry, the spongy excrescence called the oak apple, and even the stiff hard spine of the *Gleditsia*. Scarcely more than 200 species are known. The appearance presented by this very distinct race of plants, is shown in plate 2, in which a group of *Caladiums* is seen at fig. b.

**ARACHIS.** A genus of Leguminous plants, remarkable for the peculiar structure of its calyx, and the habit of thrusting its fruit into the ground. M. Poiteau, in the *Annales des Sc. Nat.*, 1853 (xix. 268), gives a good description and figure of *A. hypogæa*. The principal characters of the genus are the immensely long tube of the calyx, whose limb is two-tipped; the corolla papilionaceous and yellow; and eight stamens united into one parcel. The ovary is very small, and placed at the bottom of the very long calyx tube; it contains two ovules, and is terminated by a very long style, thickened at its extremity, and covered with hairs at the place where it comes in contact with the stamens. After the fall of the flower, the ovary, which is very small, is gradually raised upon a stalk which in time attains a length of two to three inches, and in its growth curves downwards, so that at length the small ovary at its extremity is thrust into the ground. When this happens, the ovary begins to enlarge, and ripens into a pale yellowish wrinkled slightly curved pod, often contracted in the middle, and containing two seeds. Should the ovary by some accident not be enabled to thrust its pods into the ground, it withers and does not attain perfection. The plant was originally a native of the West Indies and West Africa, but is now cultivated in warm climates, preferring a light sandy soil. The seeds which are of the size of a pea are eaten as food, but are chiefly valuable for the quantity of oil they produce when pressed. The oil is used as a substitute for that of olives, to which it is equal in quality. The plant might with much advantage be extensively cultivated in Australia and others of our colonies for the sake of its excellent oil, while the herbage would form valuable forage for cattle, who eat it greedily. The pods are known in this country as Ground Nuts. The peculiarity of thrusting the fruit into the soil to effect its maturation there, is not confined to this genus, but exists also in the allied genus *Voandzeia*, a native of Surinam, where its seeds are eaten, like those of the *Arachis*, as peas by the

[M. T. M.]

**ARACHNIODES.** A doubtful genus of Java Ferns, long supposed to belong to the *Pteridaceæ* or *Alseodaceæ*. Mr Baker has, however, ascertained that it was founded on a specimen of *Lastrea confertifolia*, from which the proper indurium had fallen, leaving only an arechnoid or cobweb-like covering. [T. M.]

**ARACHNIS** (from the Greek: a spider). A Javanese Orchid, of epiphytall habit, whose name has been derived from the extraordinary resemblance of its flowers to a huge spider. The plant has flowers five inches in diameter, of a lemon colour, with great purple spots; they grow as many as twelve together, on a long loose spike arising from one side of a strong scrambling stem. They are said to have the most delicate smell of musk, but so penetrating withal that a single spike will scent an entire meeting-hall. Kœmpfer, however, asserts that this odour resides exclusively in the ends of the sepals and petals, which are broader at the end than elsewhere; and he says that if they are cut off all fragrance ceases. The plant has had several names, as *Epidendrum flos aris*, *Aridas arachnites*, *Remantaria arachnites*, and *Arachnis moschifera*. It is called in Java, Katong ging. Undoubtedly it is one of the most remarkable plants of its remarkable order, and it is not a little surprising that it should never have been introduced into Europe.

**ARACHNITIS** is a name given to the spider *Ophrys*.

**ARACHNOID.** Resembling cobweb in appearance; seeming to be covered with cobweb, in consequence of the entanglement of long white hairs.

**ARACHNOTRICH.** A genus of plants closely related to *Bondeletia*, from which it differs in having the corolla four-parted, with its tube and throat smooth. The anthers are placed towards the top of the tube of the corolla on very short filaments. The plants are covered with a more or less cobweb-like clothing of hairs, hence the name. It belongs to the natural order *Cinchonaceæ*. [M. T. M.]

**ARADS.** An English name for the *Araceæ* or Arum family.

**ARALIA.** This genus is the type of the order *Araliaceæ*, and consists of trees, shrubs, and herbs of rather striking character, found in North America, and in New Zealand, Japan, and the East. The flowers are inconspicuous, collected in umbels, the umbels not unfrequently ranged in large compound panicles. The calyx has a very short superior limb, which is entire or five-toothed; the corolla consists of five petals inserted on the margin of the epigynous disk; the stamens are five in number, alternating with the petals; and the ovary is inferior, five to ten-lobed, with a solitary pendulous ovule in each cell, and becomes a berry-like drupe. The foliage is very various in character, but generally of an ornamental aspect; sometimes simple, entire, or lobed, sometimes digitate, pinnate, twice ternate, bipinnate, or supradecomposed. Some of the species have smooth, and others prickly stems. One of the former, *A. racemosa*, grows three to four feet in height, with a divaricately-branched herbaceous stem, bearing com-

pound leaves, the petioles of which are tripartite, each division bearing from three to five ovate or heart-shaped serrated leaflets. This plant is called Spikenard in North America, and is highly esteemed as a medicine. The roots of *A. nudicaulis*, another North American herbaceous species, were formerly imported and sold for sarsaparilla; and they are stated to be used by the Creoles, under the name of Rabbit-root, as a remedy against syphilis, and also as an application to recent wounds. *A. spinosa*, one of the prickly species, is a small, simple-stemmed tree, eight to twelve feet high, the stems and leafstalks both prickly, the leaves doubly and triply pinnated with ovate serrated leaflets, and the panicle much branched, downy, bearing numerous umbels of flowers. This is known in America under the name of Angelica tree, and the berries are used in an infusion of wine or spirits for relieving rheumatic pains and violent colic. The tincture has also been found to relieve toothache. The Rice Paper plant of China has been referred to this genus by Sir W. J. Hooker, under the name of *A. papyrifera*. This plant grows in the deep swampy forests of the island of Formosa, and apparently there only, forming a small tree, branching in the upper part, the younger portions of the stem, together with the leaves and inflorescence, covered with copious stellate down. The full-grown leaves are sometimes a foot long, cordate, five to seven-lobed, of a soft and flaccid texture. The panicles of flowers come from the extremities of the stem and branches, rising above them, and then becoming pendulous, one to three feet long, bearing the numerous capitate umbels of small greenish flowers. The stems are filled with pith of very fine texture, and white as snow, which when cut forms the article known as Rice paper. Large quantities of the stems are taken in native crafts from Formosa to Chinchew, where they are cut into thin sheets for the manufacture of artificial flowers. A lengthened account of this interesting plant will be found in *Hooker's Journal of Botany*. [T. M.]

**ARALIACEÆ** (*Araliæ*, *Ivyworts*) form a small natural order closely approaching Umbellifera, from which they in reality differ in little, except their fruit always consisting of more carpels than two, and having no double epigynous disk. They are also more generally arborescent, many of them being trees or large shrubs, and very few herbs. Several are conspicuous for their broad noble foliage. The species are found in the tropical and sub-tropical regions of the world; and in some of the coldest, as in Canada, the north-west coast of America, and Japan. *Aralia pectorata* even occurs in Lord Auckland's Islands, in 50° south latitude. They have aromatic qualities, usually slight, but occasionally intense. One of them forms a soft white spongy pith, which when cut into thin plates and flattened becomes the famous so-called Rice paper of the Chinese.

See **HEDERA, ARALIA, PANAX, GUNNERA, ADOXA, &c.**

**ARA-ROOT.** The same as Arrow-root, which see.

**ARAR TREE.** *Colletris quadrivalvis*, formerly called *Taxia articulata*, a great coniferous tree, which yields gun Sandarac.

**ARATICU DO MATO.** A Brazilian name for *Annona sylvatica*.

**ARAUCARIA.** A genus of *Conifera*, consisting of lofty evergreen trees, with verticillate spreading branches, covered with stiff, flattened, pointed leaves, usually imbricate, but more or less spreading. The spikes of male flowers are cylindrical and terminal; each anther divided into from six to twenty cells. The ripe cones in the females are large, globular, terminal, densely imbricated with numerous woody scales, sometimes winged, each bearing a single adnate seed, and many of them usually barren. There are five or six species known, all from the southern hemisphere. *A. imbricata* is the species commonly planted in this country, and the only one which will bear our climate without protection. It is a native of the mountains of Southern Chili, where it forms vast forests, attaining a great height, and supplying a hard and durable timber. The seeds are edible when fresh, and grow in sessile cones of the size of a child's head, growing at the ends of the branches. The Bunya Bunya pine, *A. Bidwellii*, a noble tree inhabiting the scrubs between the Brisbane and Burnett rivers, bears cones as large as a man's head, and which contain a number of large seeds, which are eaten as food by the aborigines. *A. brasiliensis* forms large forests in south tropical Brazil. It much resembles the Chilean species, but is rather more elegant in growth, and of a better colour. It is occasionally planted in Southern Europe, where it succeeds better than the *A. imbricata*, but is too tender for this country. *A. excelsa*, the Norfolk Island pine, attains the height of 200 feet. The leaves are much shorter than in the two preceding species, and but slightly flattened, and the scales of the cone are broadly winged, with a hooked point. It will not bear the open air in our climate, but forms a conspicuous object in lofty conservatories. It has been considered by some botanists as forming, with two Australian species, a distinct genus under the name of *Eutassa* or *Eucata*.

**ARBOL DE CORAL.** A Mexican name for *Picramnia Coralodendron*. — **DEL CERA.** A South American name for *Elaeagia utilis*. — **DE LECHE.** The Cow Tree, *Prostrum Galucodendron*. — **DE ULE.** A Mexican name for *Castilleja elastica*.

**ARBOR JUDE.** A common name for *Cercis* or Judas tree. — **VITÆ.** The common name for *Thuja*.

**ARDOUSER.** (Fr.) *Arbutus*.

**ARBRE A' CHAPELET.** (Fr.) *Melia Asedarach*. — **A' FRANGES.** *Chionanthus virginica*. — **A' LA CIRE.** *Myrica cerifera*.

*sera*. — A' PERRUQUE. *Rhus Cotinus*. — A' SULF. *Stillingia sebifera*. — AU POIVRE. *Vitex Agnus-castus*. — AUX ANEMONES. *Calycanthus floridus*. — AUX FRAISES. *Arbutus Unedo*. — AUX QUARANTE E'CUS. *Salisburia adiantifolia*. — D'ARGENT. *Leucodendron argenteum*. — DE CASTOR. *Magnolia glauca*. — DE JUDE'E. *Cercis Siliquastrum*. — DE NBIGE. *Chionanthus virginica*. — DE SOIE. *Acacia Julibrissin*. — DE STE. LUCIE. *Cerasus Mahaleb*. — DE VIE. *Cupressus thuloides*, *Thuja occidentalis*, and *Thuja orientalis*. — DU VOYAGEUR. *Ravenala madagascariensis*, sometimes called *Urania speciosa*. — SAINT. Melia *Asedarach*.

**ARBUTUS.** A genus of *Ericaceae*, consisting of trees and shrubs, natives of Southern Europe, the Canary Islands, North America, and Chili. Twenty-five species have been described. They have alternate, entire, or toothed evergreen leaves. The pedicellate and bracteate flowers are in terminal paniculate racemes; the corolla is white or reddish; the calyx inferior, and consisting of five small sepals. The deciduous corolla is globose or ovately campanulate, with a small contracted five-cleft and reflexed border. It encloses the ten stamens, which have flattened filaments, and anthers compressed at the sides, opening by two terminal pores, and attached below the apex, where two reflexed awns are produced. The ovary has five cells, with many ovules in each. There is a single style with an obtuse stigma. The fruit is a globose indurated berry, rough with granular tubercles, and containing five many-seeded cells. The berries are edible though not agreeable. *A. Unedo* is called the Strawberry tree from its fruit resembling a strawberry at a distance. When eaten in quantities this fruit is said to be narcotic. A wine is made from it in Corsica, but it has the same property as the fruit. In Spain both a sugar and a spirit are obtained from it. The bark and leaves of the same plant are used as astringents; in some parts of Greece they are employed for tanning leather. This species grows abundantly on the rocks at Killarney. It is cultivated as an ornamental shrub, and as it ripens its fruit the second year, it is peculiarly beautiful in October and November, being covered at the same time with blossoms and ripe fruit. [W.C.]

**ARBUTUS, TRAILING.** An American name of *Epigaea repens*.

**ARCEUTHOS.** (Gr.) *Juniperus Oxycedrus* and *Juniperus phænicea*.

**ARCHANGEL.** A common name for *Lamium* and *Galeobdolon*; also applied to *Archangelica officinalis*.

**ARCHANGELICA.** A genus of Umbelliferous plants, whose stems and leaves have a very powerful and agreeable aromatic smell. The *Anghica*, *A. officinalis*, is the

only species grown for culinary or medicinal purposes. Angelica is a hardy biennial, from three to six feet high, found in England in moist situations, but believed to be originally a native of the northern parts of Europe. It has been in cultivation since 1568. The leaf stalks were formerly blanched and eaten like Celery. They have, however, long ceased to be so, and are now in request for the use of confectioners, who make an excellent sweetmeat with the tender stems, stalks, and ribs of the leaves, candied with sugar. The seeds and leaves are powerfully aromatic, and are used in country places for their supposed medicinal properties. [W. B. B.]

**ARCHEGONE.** A term applied to the long-necked cellular sacs which occur in the higher or acrogenous cryptogams, and which are analogous to the pistils of phænogams. They contain at the base of their cavity a cell which is analogous to the embryo sac of phænogams, and which is impregnated by the agency of spermatozooids. From this cell, either the young plant as in ferns, or the capsule as in mosses, is formed by means of repeated cell division. [M. J. B.]

**ARCHILL, or ORCHIL.** A colouring matter obtained from various species of lichens, especially *Rocella tinctoria*.

**ARCTIUM.** One of the familiar plants, which, without culture or management, flourishes in nearly all climates and every kind of soil. To the agriculturist it is best known as a troublesome weed, always ready to make its appearance in neglected ground, growing rapidly, and with its large spreading leaves choking all other vegetation; to the artist it affords a bold and striking foreground for his landscapes; and to the school-boy its heads of flowers, under the name of burs, offer an ever welcome supply of means for playing practical jokes. The Burdock is of no utility to man, as no domesticated animals, except, it is said, the ass, will eat its leaves; though it is a question whether it might not be sown with advantage as a cover for pheasants in places where there is a difficulty in raising underwood. It was formerly commended for its medicinal virtues, and was prescribed for rheumatic affections. Some writers too, speak of its excellence as a culinary vegetable. The stems, they say, should be gathered young, stripped of their rind, and treated as asparagus. When burnt the ashes afford a large quantity of alkaline salt. It is a very variable Composite plant, four British forms, *A. majus*, *A. minus*, *A. nemorosum*, and *A. intermedium* being considered as distinct species by some botanists. Their characters are, however, inconstant, although extreme forms of each are readily recognisable; and they are perhaps better regarded as varieties of the aggregate species, *A. Lappa*. The name *Lappa* is derived from the Celtic *llep*, a hand, from its prehensile pro-

parties. *Arctium* is from *arctos*, the Great Bear, from the rough character of the plant. [C. A. J.]

*A. Lappa*, under the name of *Gobo*, is cultivated in Japan as a vegetable.

**ARCTOCALYX.** A genus of *Gesneraceae*, consisting of half-shrubby plants inhabiting the mountains of Mexico. They have ovate-lanceolate or elliptical leaves, axillary flowers of an unusually large size for the order, and of a bright orange spotted with brown or purple. The calyx is large, tubulose-bell-shaped, fifteen-nerved, and five-toothed. The corolla is funnel-bell-shaped, and the ovary sunk into the calyx, and surrounded by a glandular disk. *A. Endlicherianus* is not uncommon in our gardens. [B. S.]

**ARCTOSTAPHYLOS.** A genus of *Ericaceae*, consisting of procumbent shrubs, with small deciduous or persistent leaves, and rather small bracteate flowers, two or three together, in very short terminal racemes. It is very nearly related to *Arbutus*, differing from it in having a glabrous berry with five stones, and each stone being one-seeded. The genus has been recently very much limited. Ten species have been separated and placed under the generic title of *Comarostaphylis*, having as their distinctive characteristic a drupaceous fruit, with a single hard five to nine-celled stone, and a single seed in each cell. Five more species have been removed to the genus *Daphniodostaphylis*, which is characterised by having the ovary placed on a ten-angled, hypogynous disk, and containing six to ten cells. The restricted genus *Arctostaphylos*, containing only the two species found in Britain, has the ovary without true dissepiments. The three genera have all alike a five-partite, persistent, and hypogynous calyx, a five-lobed reflexed corolla, inserted on the calyx, and ten stamens. The two species are natives of the northern regions of both the old and the new world. The whole plant of *A. uva-ursi* is astringent; it has been used for tanning leather. The berries form a favourite food of grouse and other game. The plant is a valuable medical astringent, used to check an excessive secretion of mucus, as in urinary and bronchial affections, and even in calculus. The *Arctostaphylos alpina*, or Black Bear-berry, is the badge of the clan Ross. [W. O.]

**ARCTOTHECA.** A genus of the Composite family, consisting of two species, both perennial herbs, peculiar to Southern Africa, and found in sandy spots near the sea. *A. repens*, which has been cultivated in this country, is a branching plant, six inches to a foot high, with pinnatifid leaves, about six inches long, covered underneath, as are also the stems, with a white tomentum, and bearing solitary yellow flower-heads, nearly three-quarters of an inch across, borne on long naked stalks. The ray florets are strap-shaped and neuter, those of the disc perfect; involucreal scales

in many series; pappus none; achenes wingless and four-sided. [A. A. B.]

**ARCTOTIS.** A genus of Composites, all natives of the Cape of Good Hope, with showy orange-coloured flower-heads, of which several species occur in gardens. It has a honey-combed receptacle set with bristles, oval grooved achenes crowned with several broad membranous scales, and an involucre of numerous imbricated leaflets with chaffy margins. The *A. speciosa* is not unfrequently cultivated under the name of *A. breviscapa*, as a half-hardy border annual, though our English summers are too short and too cool to bring it to the perfection it attains in its southern home. It would probably be seen to more advantage if treated as a tender biennial. As grown in our gardens, it is a dwarf, tufted, tomentose plant, with numerous, short, prostrate stems, proceeding from the crown of the root; three-nerved leaves, varying from oval and entire to lyrate pinnatifid, in the latter case with a large terminal lobe; and large terminal flower-heads, with a brownish disk and orange-coloured ray, expanded only in fine weather during the middle of the day. Many of the species are greenhouse perennials, which would succeed in the open ground in summer in warm situations, and some of them would be desirable additions to our gardens. Of this section, probably the only attainable species is the *A. grandiflora*, with handsome deep orange-coloured capitules, four inches in diameter, and silvery-grey pinnatifid foliage, blooming freely during the whole summer, in a sunny situation and dry soil. [W. T.]

**ARCTURIA.** A section of the genus *Drosera*, of which the Tasmanian *D. Arcturi* is the type. This has three undivided styles with thickened stigmas; the stem is short, and not bulbous, with narrow leaves passing insensibly into the leaf-stalk; scape with a single white flower. [J. T. S.]

**ARCTURUS.** A genus of *Scrophulariaceae*, established by Bentham, but subsequently abolished by him; the name being retained to characterise a group of the genus *Celsia*, in which the anthers are attached by their middle. [W. O.]

**ARDISIA.** This is a large genus of the family *Myrsinaceae*, containing upwards of 100 species. They are evergreen shrubs or small trees, with alternate, rarely opposite, leaves covered with transparent dots. Their flowers are white or rose-coloured, and arranged in panicles, the branches of which are often of an intense rose colour, thereby adding greatly to the beauty of the plant. The flower-stalks are often disposed in little umbels on the branches of the panicle. They are found in India, the islands of the Indian Ocean, and America. The bark of *A. colorata* is known in Ceylon as *Dan*, and is used in native practice in bowel complaints, fevers, and externally for healing ulcers. It is tonic and astringent. *A. solanacea*, a na-

tive of India, is to be met with in some gardens; the juice of its berries is of a beautiful red colour, which, when put on paper, changes to a durable brown. *A. crenata*, a native of China and Penang, is a beautiful dwarf bush often cultivated in greenhouses. The leaves are glossy green, and in the winter season, if well managed, the plant is covered with a mass of scarlet berries, much like those of the holly. *A. primulifolia*, a native of Hong Kong, is only about six inches high, and has thin leaves like those of the common primrose. A number of species are in cultivation in English gardens. [A. A. B.]

**ARDISIADS.** An English name for the order *Myrsinaceae*.

**AREC. (Fr.)** *Areca oleracea*.

**ARECA.** The generic name applied to certain species of Palms, characterised by having a lofty stem, pinnated leaves whose stalks are rolled up into a cylinder at their base; a double spathe encloses the flowers, which are borne upon a branched spadix, and are unisexual. The male flowers have a six-parted perianth; the female flower contains six rudimentary stamens, and a superior one-seeded ovary which ripens into a drupe-like fruit with a fibrous rind.

*A. Catechu* is a handsome tree, cultivated in all the warmer parts of Asia for the sake of its fruits, which are of the size of a hen's egg, of a reddish yellow colour, and with a thick fibrous rind, within which is the seed. This is known under the name of Areca nut, Pinang, and Betel nut, and is about the size of a nutmeg, but conical in shape, flattened at the base, brownish externally, and mottled internally like a nutmeg. These nuts are cut into narrow pieces, which are rolled up with a little lime in leaves of the Betel Pepper. The pellet is chewed, and is hot and acrid, but possesses aromatic and astringent properties. It tinges the saliva red, and stains the teeth, and is said to produce intoxication, when the practice of chewing it is begun. The effects seem to be as much due to the other ingredients as to the areca nut. So addicted are the natives to the practice, that Blume tells us, 'they would rather forego meat and drink than their favourite areca nuts, whole ship loads of which are annually exported from Sumatra, Malacca, Siam, and Cochin China. The practice is considered beneficial, rather than otherwise. In this country the charcoal of the nuts is used as tooth powder, for which it is well adapted by its hardness. A sort of Catechu is furnished by boiling down the seeds of this palm to the consistence of an extract, but the greatest quantity of the drug called Catechu used in this country is the produce of *Acacia Catechu*. The flowers of the tree are very fragrant, and used on festive occasions in Borneo, where they are considered a necessary ingredient in medicines, and charms employed for healing the sick. In Malabar another species, *A.*

*Dicksoni*, is found wild, and furnishes a substitute for the true betel nut to the poorer classes.

*A. oleracea* is the Cabbage Palm, which is found in abundance in the West Indies. It derives its name from the bud which terminates its lofty stem. This bud consists of a great number of leaves densely packed, so that the inner ones are of a white colour, and delicate flavour, and serve as a vegetable. The noble trees are destroyed for the sake of this luxury; and it is related that in the cavity formed by the removal of the 'cabbage' a kind of beetle deposits its eggs, from which maggots are produced which are an article of diet much relished by the negroes of Guiana! [M. T. M.]

**AREGMA.** A remarkable genus of parasitic *Fungi*, which abound on several species of *Rosaceae*. Their first appearance is that of some yellow *Uredo*, in which condition the fruit is not distinguishable from that of the genus just mentioned, but, after a time, cylindrical dark multi-septate bodies are produced on long bulbous stalks, forming a sort of spore-shaped prothallus, the articulations of which germinate, and produce at length the true spores. Nothing is more common than the Aregma of the Rose and Bramble (*A. Rosa* & *A. Rubi*), which afford interesting objects for the microscope, and food for much reflection, from their peculiar mode of reproduction. [M. J. B.]

**AREMONIA.** A name altered from *Agrimonia*, and now applied to an evergreen herb belonging to the natural order *Rosaceae*. It grows about a foot high, and bears irregularly pinnate downy jagged leaves, of which the upper leaflets are largest, those of the stem in threes; the flowers are small, yellow, and grow in tufts. The plant is a native of Italy and Carniola. [C. A. J.]

**ARENARIA** or Sandwort. A genus of *Caryophyllaceae*, belonging to the tribe *Abuiceae*, consisting of small herbs, distinguished from the others of the tribe by having the styles generally three; the capsule opening by twice as many valves as there are styles, at last splitting down to the base; the seeds without an appendage; and the petals not cleft into two segments. The species are extensively distributed; three occur wild in Britain: *A. serpyllifolia*, which is a common annual plant, with the petals not exceeding the calyx. Some authors consider we have two species included under this name, and separate from the common form, *A. leptoclados*, which is a much more slender plant, with softer capsules. *A. ciliata*, a perennial found on Ben Bulbin, in the West of Ireland, has the petals much longer than the calyx, and the leaves fringed with hair. *A. norvegica*, also a perennial, from the Orkney and Shetland Islands, is closely allied to the last, but the leaves are not fringed. *A. trimeria* is sometimes placed in the genus *Muhlenbergia*, as the seeds have an

appendage: it, however, accords ill with the other species of that genus. [J. T. S.]

#### ARENGA. *Saguerus*.

AREOLATE. Divided off into distinct spaces usually more or less angular. The skin of a plant is areolate.

ARETHUSA *bulbosa* is a small swamp plant, belonging to the order of Orchids, with a one-leaved scape, terminated by a single very handsome rosy-purple sweet-scented flower. It is found exclusively in North America, and is the only species of its genus. Other supposed species belong to *Pogonia*.

#### ARGALOU. (Fr.) *Palturus aculeatus*.

ARGANIA. A genus of plants belonging to the family of *Sapotaceae*. The calyx has ten sepals, in two rows; the throat of the corolla has five scales or abortive stamens, alternating with the five fertile stamens; anthers opening outwardly; style awl-shaped. *A. Siderocylon* is the Argan tree of Morocco, in certain provinces of which it grows in woods. It is a spiny evergreen tree, with a trunk of considerable size, but of low stature. It gives off branches at a few feet from the ground, which incline downwards till they rest on the earth; at length, at a considerable distance from the stem, they ascend. A tree mentioned in the *Journal of Botany* for April 1854, measured 16 feet only in height, while the circumference was as much as 230 feet. The fruit is an egg-shaped or roundish drupe, dotted with white. These fruits are much relished by all ruminating animals, who, in chewing the cud, eject the hard seeds, from which a valuable oil is extracted. The culture of the plant for the sake of its oil has been recommended in Australia and certain parts of Cape Colony subject to droughts. The wood is very hard, and so heavy as to sink in water. [M. T. M.]

ARGEL, or ARGHEL. A Syrian name for *Solenostemma Argel*, the leaves of which are found amongst Egyptian scums.

ARGEMONE. The name of a genus of the Poppy family, *Papaveraceae*, thus characterised:—sepals 2-3; petals 4-8; stamens numerous; stigmas 4-7, radiating, sessile, or elevated on a very short style; capsules obovate, opening at the top by a number of little valves. *A. mexicana*, a native of Mexico, has become widely distributed over the globe, abounding in roadsides, and waste places in proximity to human habitations. The seeds possess acrid, narcotic, and purgative properties, and are employed as a substitute for ipecacuanha. They also contain an oil which has been recommended—as what has not—as a remedy for cholera. The yellow juice of the plant is used in ophthalmia. [M. T. M.]

ARGENTINE. (Fr.) *Cerastium tomentosum*; also *Potentilla anserina*.

ARGOPHYLLUM. A small genus of

Tasmanian *Breziaceae*, with alternate stalked ovate undivided leaves, silky and silvery on the under side. The flowers are very small, in terminal many-flowered corymbose or paniculate cymes. A curious cup from which the stamens rise, is cut into comb-like teeth. [J. T. S.]

ARGOUSIER. (Fr.) *Hippophidia*. — DU CANADA. *Shepherdia canadensis*.

ARGYLIA. A genus of *Bignoniaceae*, containing eight species, from Chili, of perennial herbs, with fleshy roots, an angled stem, petiolate palmate and alternate leaves, and white or purplish axillary flowers. The genus has a five-partite calyx; a tubular corolla, with a five-lobed limb; four didynamous stamens; and a bilocular ovary. [W. C.]

ARGYREIA. A genus of the natural order *Convolvulaceae*, having large handsome flowers, with a bell-shaped corolla, into the base of the tube of which the stamens are inserted. The ovary is two-celled, each cell containing two seeds, unless, as often happens, some of them become abortive. Fruit berry-like, indehiscent. They are natives of tropical Asia. The leaves of *A. bracteata* and *A. speciosa* are used in India as a poultice in cases of scrofulous disease of the joints, and as a cool application in headaches. The root of *A. malabarica* possesses purgative properties. Two or three species are in cultivation. They are climbing plants with white or purple flowers, and much resemble *Ipomoea*. [M. T. M.]

ARGYROLOBIMUM. A genus of the Pea-flower tribe of the natural family *Leguminosae*, containing upwards of forty species, all of them herbs or dwarf shrubs, with trifoliate stalked or nearly sessile leaves, having two stipules at their base, and generally covered with silvery hairs. The flowers are yellow, solitary or racemed, with bracts. About thirty species are found in South Africa, a number in the countries bordering on the Mediterranean, and some extending through Afghanistan into N.W. India. The name of the genus has reference to the pod which is often clad with silvery hairs. [A. A. B.]

ARGYRORCHIS. An obscure terrestrial Orchid from Java, with pinkish flowers. It appears to be a mere peloria of *Macodes Petola*.

ARHYNCHIUM. An Orchidaceous epiphyte from tropical Asia, with dull green and brown flowers, referred by the younger Reichenbach to *Rensathera bilinguis*. Its lip is so constructed as to look as if composed of two tongues laid one upon the other.

ARIL, ARILLUS. A body which rises up from the placenta, and encompasses the seed, like the mace in nutmeg, and the red sac in *Swongmus*.

ARILLODE. A false aril; a coating of the seed proceeding from its own surface, and not from the placenta.

**ARIOPSIS.** A curious genus of plants belonging to the *Araceæ*, and similar to the genus *Arum* in appearance, hence the name. The species were formerly included in the genus *Bemusatia*, and consist of small Indian herbs with inconspicuous stems, globose rhizomes, and glaucous heart-shaped peltate leaves, on long stalks. The spathe is nodding, boat-shaped, adherent to the lower part of the spadix, on the upper part of which the male flowers are placed in little depressions; each little cavity contains six globose anthers, bursting by one pore. The female flowers at the lower portion of the spadix consist of obliquely ovate ovaries with three to five stigmas. The fruit is like a berry, but somewhat dry, angular, one-celled, with four to five placentas, and several seeds placed in two rows along each placenta. *A. peltata* is sometimes met with in cultivation as an object of curiosity. [M. T. M.]

**ARISÆMA.** The plants of this genus of the *Arum* family have tuber-like rootstocks, from which proceed peltate, pedate, palmate, or more rarely undivided leaves. The spathe is rolled round the spadix at the base, the spadix has unisexual flowers below, its upper part covered with rudimentary flowers; the anthers are provided with distinct filaments; the ovaries are numerous, and contain 3-8 ovules, and are terminated by very short styles. The tuberous rootstocks of two species are used by the natives of Sikkim Himalaya, as food; they are beaten into a pulp with water, and allowed to ferment, a process which destroys their acridity. The Dragon-root, or Indian Turnip of America, is the tuber of *A. crotubens*, which furnishes a kind of starch. [M. T. M.]

**ARISARUM.** A genus of plants of the *Arum* family, closely allied to *Arisæma*. The lower part of the spadix has unisexual flowers, but no rudimentary ones, and is naked at the top; the ovaries are few in number, and have a distinct style. The plants are herbaceous, with a tuberous or branching and creeping rootstock, heart-shaped or spear-shaped leaves, on long stalks, and livid purple spathes. They are natives of Southern Europe and the Mediterranean region. [M. T. M.]

**ARISTA.** The awn or beard of corn, or any such like process.

**ARISTATE.** Furnished with an arista.

**ARISTOLOCHACEÆ** (*Aristolochia*, *Asarum*, *Picnolobus*, *Birtheortia*). In the tropical parts of both hemispheres, and occasionally beyond those limits, occurs a race of plants with singularly inflated irregular flowers, consisting of a calyx only, of a dull dingy colour, varying from yellow to shades of chocolate, purple, or brown, and often emitting an offensive odour. A hot summer appears to be one condition of their existence, with a few exceptions—the most striking of which are *Asarum*, little stemless plants, wild in

Europe and North America, and the *Aristolochia Clematitis*, which has become as it were naturalized in England. The wood of these plants, when they have any, consists of parallel plates, held loosely together by soft medullary processes. The ovary is inferior, with many ovules, and for the most part consists of six cells, the number three being, as in *Endogone*, characteristic of the floral apparatus of the order. In medicine these plants are slightly aromatic stimulating tonics, useful in the latter stages of low fever; the taste is bitter and acrid; the odour strong and disagreeable. They are also said to be sudorific, emmenagogue, purgative, and diuretic. The principal genera are *ARISTOLOCHIA* and *ASARUM*, which see.

**ARISTOLOCHIA.** A remarkable genus of plants belonging to the *Aristolochiaceæ*, and characterised by the possession of a calyx generally of some other colour than green, of an irregularly tubular form, inflated at its lower portion, and adherent at its base to the ovary. The stamens are five or six in number, and adhere to the solitary style; the fruit is a six-celled capsule with numerous seeds. The wood of these plants differs much in appearance from that of Exogenous trees or shrubs in general, as it consists of radiating plates of wood, surrounding a pith and encircled by the bark, not disposed in rings.

The plants of this genus are for the most part shrubs, generally climbing round the branches of trees. They are abundant in tropical South America, while a few species are distributed throughout North America, Europe, and India. One species, *A. indica*, is common to India and to New Holland. The flowers of some of the kinds are remarkable for the oddity of their form, and for their large size. Humboldt mentions one, *A. cordata*, as growing on the shady banks of the Magdalena, and having blossoms measuring four feet in circumference, and which the Indian children sportively draw on their heads as caps. *A. Clematitis*, the common Birthwort, is found in this country, but generally in the neighbourhood of old ruins, as if it had at some time been cultivated in the gardens attached to such buildings; probably for medical purposes, as an aid in parturition. It is a low-growing shrub, with slender erect greenish furrowed stems, stalked heart-shaped leaves, in the axils of which the yellowish trumpet-shaped flowers are produced in clusters. Others of the species had formerly a similar reputation, such as *A. rotunda* and *A. longa*.

*A. Serpentaria* is the Virginian Snake-root, furnishing the drug known as *Serpentary*, which is esteemed in the southern states of America as a cure for the bite of the rattlesnake or of a mad dog. Its effects, when given in large doses, are a feeling of sickness, purging, and subsequently increased fullness of the pulse; hence it is still occasionally used as a stimulant in fevers.

The roots of other species are used in the United States for the same purposes, as *A. hastata* and *A. tomentosa*; and several kinds are employed in Brazil for their stimulant properties. Many of these plants, besides those above mentioned, are said to be useful in effecting the cure of snake bites, not only in tropical America, but also in the West Indies, Hindostan, and Egypt. It is stated that the Egyptian jugglers use some of these plants to stupefy the snakes before they handle them; and Jacquin relates that the juice of the root of *A. angulicida*, if introduced into the mouth of a serpent, so stupefies it, that it may be handled with impunity. If the reptile be compelled to swallow a few drops, it perishes in convulsions; hence it is perhaps, on homœopathic principles, that the root is affirmed to be an antidote to snake bites. *A. bracteata* and *A. indica* are both used for similar purposes in India, so that there is the concurrent testimony of the natives of different quarters of the globe as to the peculiar property of these plants. The two kinds just named are bitter plants, used as purgatives and vermifuges, and for other purposes in India.

In Central America one or more plants, called Guaco by the natives, are held in high esteem for the cure of snake bites. It is conjectured, with much probability, that the Guaco is some species of *Aristolochia*. So satisfied are the natives of Peru, Central America, and Mexico of its extraordinary medicinal powers and specific virtues in cases of snake bite, that every Indian or Negro who has to traverse the country, invariably has a supply of this friendly plant in a dry or prepared state, to meet any accident that may befall him, by inadvertently placing his foot upon one of these dreaded and deadly foes of mankind. Mr. Temple, to whose account of this plant, published in the *Journal of the Society of Arts* for the year 1855, we are indebted in drawing up this notice, states that he employed the tincture in four cases of snake bite with complete success. He also gives a strange account of the way in which the Guaco is reported to have been first discovered, the substance of which is as follows:—A traveller passing through a forest observed two formidable snakes engaged in deadly encounter; after a short time one was severely bitten and fled from the scene of conflict, until it reached a creeping plant, of the leaves of which it partook with greediness—that plant was the Guaco. He secured the reptile, and brought away the plant the leaves of which it had eaten. The snake, although bitten by one of a most deadly species, quite recovered. Another report, as probable as the other, is that snakes have been observed carefully to avoid localities where the plant grows. Many persons are so firmly persuaded that the snake will not approach the Guaco, that when travelling in the bush, they carry a small piece of the root of the plant in their pocket. So then, this wonderful plant prevents the access of

snakes, stupefies them, and kills them if they do come, and cures them if bitten by a fellow snake, and likewise cures human beings bitten by these venomous reptiles. There can be no doubt of the partial truth of some of these statements, and hence, not only the botanical history, but the medical properties of Guaco, demand accurate investigation.

*Aristolochia grandiflora.*

Several different kinds of *Aristolochia* are cultivated in hot-houses for the singularity, and in some cases for the handsome appearance, of their flowers, albeit their colour is usually of a dingy hue. The flowers of various species act as a sort of fly-trap: the flowers are bent in the middle, and lined with hairs pointed downwards, so that ingress is easy but escape impossible to the unlucky insect, which thus, it may be unconsciously, aids in the ripening of the seed. *A. Sipho*, a native of the Alleghany mountains, is cultivated as a climbing plant, out of doors, for the sake of its large, heart-shaped leaves; the flower is curved like a siphon, hence its name; it has also received the name of Pipe-vine, from a resemblance in the form of the flowers to that of a tobacco-pipe. (M. T. M.)

**ARISTOTELIA.** A genus of the natural family *Simarubaceae*. There are five species known: shrubs or small trees with opposite or ternate stalked leaves, which vary much in size and form. The flowers are small and white, arranged in axillary fascicles or in racemes; the berries roundish, varying in colour from pink to black, and in size from that of a small pea to a cherry. The wood of *A. Macouat*, a native of Chili, is used for making musical instruments, its tough bark forming the strings. The berries are acid but eatable, and a wine is made from them by the Chilians which is given in malignant fever. 'It was employed by Domby in Chili during the plague of 1782, with boasted success. Two species are found in N. Zealand: the berries of *A.*

*racemosa*, the Mako-Mako of the natives, are eaten. The genus is named in honour of the Greek philosopher. [A. A. B.]

**ARJOONA.** A genus of *Oleaceae* or *Santalaceae*, containing three species of undershrubs or herbs, with alternate rigid and acute leaves, and flowers in spikes at the ends of the branches. The calyx consists of a cylindrical five-lobed tube. The stamens, five in number, have slender filaments and oblong anthers. The inferior ovary is fleshy and contains three ovules. There is a thread-like style, and three short linear stigmas. The fruit, included in the persistent bracts, is one-seeded. The species are natives of South America. [W. C.]

**ARMARINTHE.** (Fr.) *Cachrys*.

**ARMATURE, ARMS.** Any kind of defence consisting of spines, prickles, &c.

**ARMENIACA.** The Apricot, *Prunus Armeniaca*.

**ARMENIACUS.** Apricot-coloured; also, native of Armenia.

**ARMERIA.** Thrift. A genus of *Plumbaginaceae*, with narrow often grass-like leaves and naked scapes, terminating in compact heads, almost like those of the Scabious, surrounded by an involucre of bracts, the two outermost of which have the bases produced downwards, forming a cylindrical sheath or tube, enclosing the upper part of the scape. The flowers are rose-coloured, purple or white. Two species are included in the British Flora; but one of them, *A. plantaginifolia*, which has the leaves three or five-nerved, broader towards the end, is only found in Jersey. The other, *A. vulgaris*, is the common Sea-Pink or Thrift, and occurs on all the coasts and many of the mountains of the British Islands: the leaves are narrow and parallel-sided. This plant is often cultivated in gardens, in place of box edging. [J. T. S.]

**ARMILLARIA.** A sub-genus of *Agaricus*, distinguished from other white-spored groups by its partial ring-like veil, without any universal volva, which remains attached to the stem. *Agaricus melleus*, a species common on almost every rotten stump in autumn, is the most prominent example met with in this country. This is frequently eaten abroad under the name of Halimasch; but it is very acrid, and causes a strong constriction of the throat when eaten raw. It would not be an acceptable article of food in this country, even were it free from danger. The sub-genus is so decidedly artificial that, with great propriety, the different sections of which it is composed, might merge as ring-bearing species amongst other white-spored sub-genera, as *Tricholoma*, *Clitocybe*, and *Collybia*. [M. J. B.]

**ARMOISE.** (Fr.) *Artemisia*.

**ARMORACIA.** The Horse-Radish, *Cochlearia Armoracia*.

**ARNEBIA.** A small genus of oriental and North African *Borraginaceae*, allied to *Lithospermum*, but having the style blind at

the apex, and the stigmas often forming four lobes. The species are small and very hispid or bristly, with pale yellow or purplish-blue flowers. [J. T. S.]

**ARNICA.** The name applied to a genus of the Composite family, distinguished by the following characteristics:—Involucre bell-shaped, of two rows of bracts; outermost florets strap-shaped, containing pistils only with rudimentary stamens; central ones tubular, five-toothed, containing both stamens and pistils; the tube of the corolla hairy; style with long arms covered with downy hairs; fruit cylindrical, tapering at each end, ribbed, hairy, and surmounted by a pappus, consisting of close rigid rough hairs arranged in one row.

*A. montana*, the Mountain Tobacco, is a native of Central Europe. Its roots and leaves possess powerfully acrid properties, but in small doses it is employed as a stimulant in low fevers and other conditions of debility, also in paralytic affections; externally it is much used as a tincture applied to bruises, wounds, and sprains. It promotes the speedy absorption and removal of the effused blood. The peculiar properties seem especially due to a resinous substance called *arnicin*, and to a volatile oil. [M. T. M.]

**ARNOLDIA.** The name of a section of the genus *Dimorphotheca*, which see. The same name was applied by Blume to a Java plant, which is now placed in the genus *Weinmannia*.

**ARNOSERIS.** An insignificant native annual weed belonging to the tribe *Clethraceae*, of the order of compound flowers. It grows from six to eight inches high, with a branched leafless stem, the upper branches being hollow and singularly swollen upwards so as to assume a club-shaped form. The flowers are small and yellow. By Smith, Hooker, and others, it is placed in the genus *Lapsana*, from which it was separated by Gartner on account of the fruit being crowned with a pappus of many short entire broad scales; in *Lapsana* the fruit is naked. [C. A. J.]

**ARNOTTO** or **ANATTO.** *Bixa Orellana*.

**ARONICUM.** A genus of the Composite family, closely allied to, and only differing from *Doronicum*, in all the achenes being furnished with a pilose pappus, instead of those of the disk only. There are four known species, all of them pretty perennial herbs restricted to mountain districts in Central Europe and Asia. They have stems varying from three inches to two feet high, terminating in one or more yellow-rayed flower-heads, sometimes two inches across; the root-leaves are stalked, heart-shaped or oblong, and toothed, with a smooth or downy surface, and those of the stem sessile and arranged alternately—not opposite as in the nearly allied genus *Artemisa*. *A. Onos* is a neat little Alpine species, three to five inches high, fre-

quently met with in collections of Alpine plants. [A. A. B.]

**ARPOPHYLLUM.** Under this name are collected about four species of epiphytal Orchids, inhabiting Mexico and New Grenada. They have slender bulb-like stems, invested with stout sheaths and one or two narrow leathery leaves at their tip. The flowers are collected in close cylindrical spikes, are small, somewhat globose, and have a rich deep crimson colour. One of the species, *A. cardinalis*, is as much as three feet high. One or two species exist in gardens, where they are valued for their elegant manner of growth. *A. alpinum* is the hardiest, inhabiting Mount Totanican, at the elevation of 10,000 feet above the sea level, where it rides on the branches of the Mexican alder, in a region where oaks refuse to grow.

**ARRABIDÆA.** A genus of *Bignoniaceæ*, composed of about twenty South American, chiefly Brazilian species, all of which are climbing shrubs, having, when young, pinnate or trifoliate, when old bifoliate leaves, generally furnished with tendrils. The genus may be readily distinguished from all other *Bignoniaceæ* by having by far the smallest flowers in the order, the corollas being, in some instances, only three to four lines long; also by its stamens, four of which are fertile, whilst the fifth is sterile and of equal length with the rest. The calyx is cup-shaped; the corolla hypocrateriform; the fruit a dehiscent, smooth, flattened capsule, linear in shape, and having a septum placed parallel with the valves of the latter. The flowers, though small, are arranged in large terminal panicles, and render the *Arrabidas* ornamental objects. The leaves of several have a deep rose or purplish tint, and are used for dyes. One of these species is *A. rosea*, from which a purplish colour is extracted in the forests of Rio Negro, and imported to Europe. The doubtful *Bignonia Chica*, probably also a congener, furnishes, by boiling its leaves in water, a red feculent substance, which is quickly precipitated by adding some juices of the bark of an unknown tree, called Arayana: the Indians use it for painting their body red. It is also an article of importance to dyers. In nature it approaches the resins, but contains some peculiar properties; it gives an orange colour to cotton. *Bignonia* (?) *Chica*, termed 'Chica' in the Orinoco districts, is probably identical with the 'Carajura.' In the Isthmus of Panama it is known as 'Hojita de teñir,' and used for dyeing Spanish hammocks. Silk-worms fed with the leaves are stated to produce red silk. [B. S.]

**ARRACACHA.** A name applied by the natives of the northern parts of South America to several kinds of plants, possessing tubers or tuberous roots, but, botanically speaking, confined to a genus of Umbelliferous plants allied to the hemlock. Its principal distinguishing characteristics are—limb of the calyx entire;

petals ovate or lance-shaped, purplish, with the point bent inwards; fruit turgid, compressed from side to side, wingless, surmounted by the thickened bases of the style; albumen curved. *A. esculenta* is cultivated in the cooler mountainous districts of Northern South America, where the roots form the staple diet of the inhabitants. The plant is somewhat like the hemlock (*Conium maculatum*), but its leaves are broader, its stem not spotted, and its flowers are of a dingy purple colour; the roots are large and divided into several fleshy lobes of the size of a carrot, which when boiled are firm and have a flavour intermediate between a chestnut and a parsnip. Trials have been made to cultivate the plant in this country, but the climate has not been found suited for it. It might be tried in some of our colonies with advantage. [M. T. M.]

The name Arracacha is also given to one of the tuber-bearing species of *Oxalis*, *O. crenata*. [T. M.]

**ARRÊTE-BŒUF.** (Fr.) *Ononis procurrens*.

**ARRHENATHERUM** A genus of Grasses of the tribe *Avenaceæ*, distinguished chiefly by having two florets within the glumes, the lower of which is abortive. The only British species is the tall Oat-grass, *A. avenaceum*, which in many instances forms a very considerable portion of good meadows and pastures. Although a large growing species, and one which cattle appear to like, it is found, on being chemically analyzed, to be low in nutritive properties compared with some other kinds, consequently, it is mostly cultivated as a portion in mixtures of grasses, and never alone as a crop. For this purpose it is useful in assisting the weaker stemmed kinds to stand upright while ripening. The few species which were formally included under this genus, as defined by Beauvois, will be found described under the genus *Avena* in *Steudel's Synopsis*. [D. M.]

**ARROCHIE ÉPINARD.** (Fr.) *Atriplex hortensis*. — FRAISE. *Bilum capitatum*. — POURPIER. *Atriplex portulacoides*.

**ARROW-GRASS.** A common name for *Triglochin*. The name Arrow-grass is also applied to the *Juncaginaceæ* generally.

**ARROW-HEAD.** *Sagittaria sagittifolia*.

**ARROW-ROOT.** A pure kind of starch obtained from various plants, and employed for dietary and other purposes. That called Bermuda or West Indian Arrow-root is obtained from *Maranta arundinacea*. Brazilian Arrow-root or *Tylocea* meal is obtained from *Manihot utilisima*. Chinese Arrow-root is said to come from the tubers of *Nelumbium speciosum*. East Indian Arrow-root is obtained from different species of *Chorea*. English Arrow-root is the starch obtained from the tubers of the potato, *Solanum tuberosum*. The seeds of *Dionedule* furnish a kind of Arrow-root in Mexico. Oswego Arrow-root is obtained in

— from Indian corn, *See Maize*. A kind of Arrow-root, called *Tous les mois*, which comes from the West Indies, is supposed to be the produce of *Canna edulis*, *C. Achras*, and probably of other species. That of the Sandwich and South Sea Islands comes from *Touss ginnatylus* (*oceanica*). Portland Arrow-root comes from *Arum maculatum*. Though the name Arrow-root is applied to the produce of various plants, it is more particularly associated with that of the *Morinda*. The word is said to be a corruption of the name *Ara-root*. [T. M.]

**ARROW-WOOD.** An American name for certain species of *Tiburnum*.

**ARRUDEA.** A genus of the Mangosteen family (*Clusiaceae*), differing from *Clusia*, to which it is most nearly related, in having a many-leaved calyx, a larger number of petals and stamens, as well as a stalked stigma. Three species are known; two of them found in Brazil, the other in Surinam. Their leaves are opposite, smooth and leathery, and their flowers solitary, stalked at the ends of the branches, and sometimes as large as those of a camellia. *A. clusioides*, a Brazilian species, is said to be a small tree, from the branches of which a viscid gum exudes; while *A. rosea*, the Surinam species, is said to grow on the trunks of other trees which it clasps with its long stringy roots so tightly as eventually to kill them. As in the other species, a gum exudes from the stems, which sometimes are upwards of forty feet long, while their greatest thickness is two and a half feet. The genus is named in honour of M. Arruda de Camara, who wrote on fibrous plants of Brazil. [A. A. B.]

**ARTABOTRYS.** A genus of plants belonging to the family of *Anonaceae*. Its name is derived from the hook-like form of the flower-stalks, by the aid of which the fruit is hung or suspended. The prominent characters of the genus are: hooked woody flower-stalks; three sepals, coherent at the base; six petals in two rows, all of the same shape, and so placed in the flower-bud that they touch by the margins only, hollowed at the base, and constricted around the ovaries; numerous densely packed stamens; ovaries indefinite in number, each containing at the base two erect ovules. The plants constituting this genus are shrubs or climbing plants, natives of India and the Indian Archipelago chiefly, but one is found in the western part of tropical Africa. *A. odoratissima* is cultivated as an ornamental shrub, and for the sake of its fragrant flowers, throughout the East, and also in hot-houses in this country. The leaves of certain kinds are highly esteemed in Java, against cholera, their value being probably dependent on the warm aromatic principle pervading them. [M. T. M.]

**ARTANEMA.** A genus of *Scrophulariaceae*, synonymous with *Achimenes* of Vahl. It is characterised by a five-parted subequal calyx; a funnel or bell-shaped corolla, bear-

ing four scales inside the tube, and having a four-cleft somewhat two-lipped limb, the upper segment of which is broader; four didynamous stamens inserted in the tube of the corolla, the hinder ones shorter; a simple style with a bilamellate stigma; and a two-celled ovary containing many ovules. The species are glabrous herbs of India and the East, and have opposite leaves, with terminal racemes of flowers. *A. fimbriatum* is an ornamental species, sometimes seen in gardens. [T. M.]

**ARTANTHE.** The name of a genus of plants belonging to the Pepper family (*Piperaceae*). They are woody plants with jointed stems, rough leaves, and spikes of flowers opposite the leaves. The flowers are perfect with pedicelate or hooded bracts. *A. elongata*, formerly called *Piper angustifolium*, furnishes one of the articles known by the Peruvians as *Matico*, and which is used by them for the same purposes as cubeba, the produce of a nearly allied plant; but its chief value is as a styptic, the rough leaves of the plant having the power of staunching blood. The under surface of the leaf is rough, traversed by a network of projecting veins, and covered with hairs; hence its effect in stopping hæmorrhage is probably mechanical like that of lint, cobweb, and other commonly-used styptics. It has also been employed internally to check hæmorrhages, but with doubtful effect. Its aromatic bitter stimulant properties are like those of cubeba, and depend probably on a volatile oil, a dark green resin, and a peculiar bitter principle called *matine*. *A. adnata* is made use of in Brazil for its pungent aromatic stimulant qualities, as well as for its specific effects. Other plants appear to furnish leaves having similar properties, and called by the same name by the Columbians. See *EUPATORIUM*. [M. T. M.]

**ARTEMISIA.** A genus of plants commonly called Wormwood, belonging to the tribe *Senecioneae* of the *Compositae*. The Wormwoods are shrubby or herbaceous plants with their leaves usually much divided and frequently of a grey colour. The flower-heads are small, borne in panicles, and provided with an involucre of overlapping bracts; the florets are as long as the involucre, yellow or greenish, either all tubular and five-toothed, or the central ones tubular, five-toothed and barren, and the outer ones filiform or three-toothed, female and fertile; the florets are placed on a receptacle without scales, and the fruits are obovate and not provided with a pappus. The genus is widely distributed over the temperate and warmer temperate regions of the globe, and most of them are remarkable for their strong odour and bitter taste. Three or four species grow wild in this country. In certain of the Western states of North America, as Utah, Texas, New Mexico, &c., are large tracts almost entirely destitute of other vegetation than that afforded by certain kinds of *Artemisia*, which cover vast plains, and

give them an universal greyish green hue. The plants are known under various names by the trappers, who find the gnarled and interlacing branches an almost insurmountable obstacle to man or horse. The plants, moreover, are of no value as forage. The few wild animals that feed on them are said to have their flesh rendered of a bitter taste in consequence. The *Artemisia*s also abound in the arid soil of the Tartarian Steppes, and in other similar situations.

The Common Wormwood, *A. Absinthium*, is found wild in some parts of Britain and cultivated in cottage-gardens. It possesses aromatic bitter and tonic properties, and was formerly much employed as a vermifuge. The active properties of the plant, and probably those of the other kinds used for like purposes, depend on a volatile oil, a peculiar bitter principle called *absinthine*, and an acid called *absinthic acid*. What is called salt of wormwood is an impure carbonate of potash, obtained from the ashes of wormwood.

A large number of the species possess similar properties to those found in the common wormwood, and are hence used for the same purposes in various parts of the world. The flower-stalks and heads of several species of *Artemisia* are sold by herbalists under the name of Wormseed: they are chiefly imported from the Levant, and are the produce of plants growing in Syria, Persia, and Barbary. Others imported from India are employed as vermifuges. *A. Moxa* is said by Dr. Lindley to be the plant used by the Chinese and Japanese in the formation of their Moxa, a small pellet of combustible material, placed on the skin and burnt there so as to produce a sore. It is used for the same purposes, and on the same principle as a blister, but it is exceedingly painful and now very rarely employed. Some of the species of *Artemisia* growing in Switzerland are used in the manufacture of the bitter aromatic, *Extrait d'Absinthe*.

The Southerawood of gardens, *A. Abrotanum*, sometimes called by country people Old Man, is a shrub with finely divided greyish green leaves, which have a fragrant aromatic odour, said to be disagreeable to bees and other insects. The plant is a native of the South of Europe.

The Tarragon, *A. Dracunculus*, differs from the majority of its fellows in that its leaves are undivided; they are narrow and lance-shaped, of a bright green colour, and possess a peculiar aromatic taste, without the characteristic bitterness of the genus. The plant is a native of Siberia. [M. T. M.]

**ARTHANITA.** (Fr.) *Cyclamen europæum*.

**ARTHROBOTRYX.** A name proposed for a small group of Indian Ferns, now referred to *Lastrea*. [T. M.]

**ARTHROCNEMUM.** A genus of *Chenopodiaceæ*, separated from *Salsicoria* to receive *S. frutescens* and a few other species, which differ from the restricted *Salsicoria* in having the flowers hidden in the articulations of the branches, and not concealed

in excavations in the axis. The calyx also is trigonous or tetragonous, with three to five teeth, and without wing or appendage. The seed has a distinctly double integument, while in *Salsicoria* it is single. Otherwise the two genera agree. They have perfect flowers, without scales; one or two stamens; two styles; and an ovate one-celled and one-seeded ovary. The species are found in the salt marshes of all parts of the world. *A. frutescens* is abundant on the British coasts. [W. C.]

**ARTHROLEPIS.** The name given to a genus of the Composite family (*Compositæ*). There is but one species known, a perennial herb, native of Syria, a foot high, with alternate linear pinnatifid leaves, the segments very small and closely overlapping each other. The flower-heads are single at the ends of the branches; the ray florets yellow. All the parts of the plant are covered with a white mealy pubescence. It is nearly related to the Chamomiles (*Anthemis*) and the Millifolias (*Achillea*); differing from the first in its winged achenes, from the second in its single flower-heads, and from both in the jointed scales of the involucre. The name of the genus is derived from this latter circumstance. [A. A. B.]

**ARTHROLOBIUM.** An unimportant genus of Leguminous plants distinguished from the equally unpretending *Ornithopus*, by the heads of flowers being destitute of a floral leaf, or bract, at the base. There are two European species, one of which, *A. ebracteatum*, grows in the Channel Isles and in Sicily. It is a small plant with prostrate stems, pinnate leaves, and minute cream-coloured flowers veined with crimson, growing in heads of four or five, and succeeded by as many jointed and curved pods, which together bear a singular resemblance to a bird's foot. [C. A. J.]

**ARTHROPHYLLUM.** A genus of the *Bignonia* family, containing five species, all of them shrubs or small trees, found in Madagascar and the islands of Eastern tropical Africa. Their leaves are compound, opposite, or alternate, and very peculiar in structure; indeed, in four of the species no true leaves may be said to be developed, but their petioles, or leaf-stalks, are winged and leaf-like, with two to four joints, the segments between the joints being wedge-shaped, and the terminal one acute. In *A. Thapsariolum* leaflets are produced from the joints of the petiole. Their flowers are generally large and tubular, disposed in racemes or corymbs from the ultimate forkings of the branches. *A. madagascariense* is cultivated in England. Its flowers are pink in colour, large and tubular; the limb of the corolla five-lobed, with crisped margins. The name *Arthrophyllum* signifies jointed leaf. It has been changed by some authors to *Phyllanthron* because the name *Arthrophyllum* is given also to a genus of the *Aralia* family. [A. A. B.]

**ARTERPODIUM.** A genus of Australian and New Zealand *Liliaceæ*, allied to *Anthericum*, with grass-like radical leaves, fasciculate roots, and small purplish or white flowers in lax racemes or panicles; the filaments of the stamens are clothed with fine short hairs for half their length. A few of the species are cultivated in this country in greenhouses. [J. T. S.]

**ARTHEROPTERIS.** A name proposed for a few tropical Ferns distinguished by having a jointed stalk. They are referred severally to the genera *Lastreæ*, *Nephrolepis*, and *Polypodium*. [T. M.]

**ARTHROSTEMMA.** A genus of tropical American *Melastomaceæ*, which have little resemblance to each other, but agree in having the parts of the flower in fours, the anthers eared at the base, the ovary bristly at the apex. Some of the species are handsome, resembling the *Rhæxus*. A few of the species are cultivated in our stoves and greenhouses. [J. T. S.]

**ARTHIROTAXIS.** A genus of *Coniferae*, consisting of much branched evergreen trees of no great height, with short, thick, densely imbricated leaves, closely covering the branches. The male flowers form very short terminal spikes with two-celled anthers. The ripe cones are also terminal, sessile, small, and globular, with almost woody peltate scales, each bearing three to six inverted seeds. There are only three species, natives of Tasmania. The name is more correctly written *Athrotaxis*.

**ARTICHAUT.** (Fr.) *Cynara Scolymus*.

**ARTICHOKE.** *Cynara Scolymus*. —, **JERUSALEM.** *Helianthus tuberosus*.

**ARTICULUS.** A joint; a place where spontaneous or easy separation takes place.

**ARTILLERY PLANT.** *Pilea scryphillifolia*, and *hernariæfolia*.

**ARTOCARPACEÆ** (*Artocarpeæ*, *Artocarpæ*). A group of apetalous trees, belonging to Lindley's Urtical alliance, not unlike the plane trees of Europe, but for the most part inhabiting the tropics and always the warmer parts of the world. They abound in a milky juice, and have for the most part their female flowers collected into fleshy masses or heads. Moreover, they have great sheathing convolute stipules like those of a fig tree. The more important genera are *ARTOCARPUS* and *ARTIUM*; which see.

**ARTOCARPUS.** This name, signifying Bread-fruit, is applied to the genus of trees furnishing the well-known fruit so called. It gives also the name to the order *Artocarpaceæ*, and is distinguished by having its male or stamen-bearing flowers borne on long club-shaped spikes, and the pistil-bearing ones in round heads. The male flowers have a tubular calyx of two sepals containing a single stamen; the female flowers have a simple ovary, containing a single ovule, and surmounted by a style with two stigmas curved down-

wards. These female flowers soon grow together, and form one large fleshy mass, which becomes the fruit, which is thus formed exactly in the same way as the mulberry is, but in the bread-fruit farinaceous matter takes the place of the sugar and vegetable jelly of the former.

The Bread-fruit tree of the South Sea Islands (*A. incisa*) is a moderate-sized tree, whose young branches are marked with ring-like scars indicating the spot where the large convolute stipules have been placed. The leaves are large rough dark green, divided into lobes, something like those of a fig tree. The fruit is roundish, of the size of a melon, rough on the exterior, marked with hexagonal knobs, or in some of the varieties smooth and of a green colour. The pulp in the interior is whitish, and of the consistence of new bread. It is roasted before it is eaten, but has little flavour. The best varieties contain no seeds, the tree being propagated by shoots that spring from the roots. The tree contains a viscid milky juice, containing caoutchouc, which is used instead of glue, and for caulking the canoes of the South Sea Islanders, who

*Artocarpus incisa*.

make use also of the timber of the tree, which is soft, and is said to attain a mahogany colour by exposure. The bark of the young tree is also fabricated into a coarse cloth. In the South Sea Islands, the Bread-fruit constitutes the principal article of diet, which is prepared by baking it in an oven heated by hot stones. The plant is now cultivated in the West Indies, but does not equal the plantain as an article of food. The history of its introduction into these islands is associated with the well-known incidents of the mutiny of the

crew of the 'Bounty,' which had been sent out under the command of Lieut. Bligh to procure Bread-fruit trees, at the earnest request of Captain Cook, and the naturalists who accompanied him in his voyages. The first attempt was frustrated by the mutiny of the crew after the plants had been procured, and all promised well. A second attempt, four years subsequently, proved successful.

The Jack, *A. integrifolia*, is a native of the Indian Archipelago; it produces a fruit like that of the above-named kind, but the leaves are not at all lobed or divided. It is cultivated in Southern India and all the warm parts of Asia. The fruit is a favourite article of food among the natives, as also are the roasted seeds. The timber is much used for making furniture; it is at first of a pale colour, but subsequently becomes dark, approaching to a mahogany tint. Bird-lime is manufactured from the juice. *A. hirsuta*, a native of Malabar, possesses similar qualities. *A. incisa* is shown in Plates 2a and 7c. [M. T. M.]

**ARUM.** A genus of plants of the family *Araceæ*, known by having a large spathe, whose edges are rolled over one another at the base. The flowers are unisexual, and placed on a fleshy spike or spadix, which is club-shaped and destitute of flowers at the summit, but at the lower portion bears male flowers or stamens, consisting merely of anthers, opening by lateral slits, unprovided with filaments, and not invested by a perianth. Between the male flowers and the female are a number of abortive flowers having the appearance of threads or hairs. Quite at the base of the spadix the female flowers are placed; these consist merely of ovaries, containing two to six ovules, and ripening into a berry-like fruit.

The common Arum of the hedges (*A. maculatum*), or, as it is commonly called, Lords and Ladies, or Wake Robin, is an extremely acrid poisonous plant, but by drying, or the agency of heat, the acrid matter is destroyed. It has a whitish rootstock, from which proceed ovate arrow-shaped green leaves, frequently marked with dark blotches and placed on long stalks; the spathe is green. The spadix is of various shades of purple, or more rarely of a dull yellowish colour. When the fruits are ripe, they are of a brilliant red colour, and very conspicuous, as not only the tops of the spadix, but also the investing spathes wither, and fall off as the fruit attains to maturity. From the tubers of this plant, in the Isle of Portland, a starch called Portland Arrow-root was formerly extensively prepared by pounding the tubers with water, and then straining. On allowing the strained liquid to stand the starch was deposited. Care was necessary from the extremely acrid nature of the plant. Indeed, Mr. A. Irvine, in his *Illustrated Handbook of British Plants*, records that many hours' boiling did not suffice to dissipate the acrid matter.

*A. italicum* has been found to grow in the

Isle of Wight. It is a much larger plant than the common *A. maculatum*, the leaves, with white veins, have the lobes at the base spreading more widely than in that species, and the spathe is rolled backwards at the point as the flowers open.

The root of *A. montanum* is used in India to poison tigers. The roots of *A. lyratum* furnish an article of diet to the natives of the Circar mountains. They require, however, to be carefully boiled several times, and dressed in a particular manner, to divest them of a somewhat disagreeable taste.

All the species of *Arum*, and those of allied genera, such as *Arisema*, *Colocasia*, *Caladium*, *Amorphophallus* and others, possess a similar combination of extremely acrid properties, with the presence of a large quantity of farina, which can be separated from the poisonous sugruent by heat or water, or by merely drying in some instances.

*A. Dracunculus* is commonly cultivated in gardens for the sake of its large pedate leaves, its spotted stem, and purple spadix. The smell is foetid, and apt to produce headache. The *Arums* have been made use of in experimenting upon vegetable heat, as by reason of the investing spathe, the heat generated by the flowers does not so easily escape as in other plants, and its degree can the more readily be ascertained. Moreover, it appears that these plants really do generate more heat than other flowers; for instance, a difference of more than 50° is recorded between the temperature of the air and that of the flowers of *A. cordifolium*. [M. T. M.]

**ARUM. ARROW.** *Peltandra virginica*, W. WATER. *Calla palustris*.

**ARUM D'ÉTHIOPIE.** (Fr.) *Richardia æthiopica*.

**ARUNDINARIA.** Reed-like terrestrial Orchids, with slender stems and narrow-ribbed leaves. The flowers are large, thin, richly coloured with rose or purple, but very fugitive. Three or four species are known, all inhabitants of tropical Asia. The genus is nearly allied to *Bittia*.

**ARUNDINARIA.** A genus of Grasses belonging to the tribe *Rambusida*. The species are either of a shrubby or arborescent nature, with strong jointed stems, resembling those of the bamboo cane. They are mostly from the warmer parts of the globe, and in some instances attain a great size, where they grow spontaneously. *A. falcatia* is one of the hardest kinds, being able to bear the cold of ordinary winters in Britain, especially in the southern counties of England and Ireland. In the county of Cork, several brakes were planted of this plant about the year 1648, and in ten years after the canes had reached a height of from sixteen to twenty feet, being nine inches in circumference at the base. The joints on the stems are nearly of equal growth, and owing to their re-

gularity the plantations present a curious appearance, to those, particularly, who have not seen tropical vegetation. In Nepal and on the slopes of the great Himalayan

purpose it is valuable, resisting, as it does, the effects of weather a long time, owing to the large amount of silica contained in the joints and on the cuticle of the stems.

Another important species is *A. Schomburgkii*, a native of Gulana, where the straight canes attain a height of sixteen feet and upwards, with a circumference of one to one and a half foot at their base. It is this plant which chiefly furnishes the tubes to the native Indians, from which they blow their poisoned arrows, which after being dipped in the deadly woorai poison, act with such fatal effect on the victims they are aimed at. [D.M.]

**ARUNDO.** A genus of grasses typical of the tribe *Arundineæ*. This genus, as now defined by Steudel and other authors, excludes the British species, which were formerly included in it: they will be found in the genera *Poa* and *Phragmites*. *A. Donax* is one of the most important kinds, and may be seen occasionally cultivated in British gardens, for the ornamental effect it produces when growing in groups. The stems attain a height of eight to ten feet in this country; but in Spain and other parts of the south of Europe they grow much taller. The leaves are broad, of a fine glaucous green colour, and in one variety they are beautifully striped in different colours, similar to those of the common ribbon-grass of gardens (*Phalaris arundinacea variegata*). The reeds are sometimes used in making bagpipes and some other musical instruments. Lady Calcott, in the *Scripture Herbal*, considers it probable that *A. Donax* is one of the plants alluded to in Scripture as the Reed, especially when the original word is 'kaneh.' The canes being long, straight, and light, make admirable fishing-rods, and excellent arrows: the latter quality being of great importance to the warlike Jews, after they began to practise archery with effect. The heroes of Homer made their arrows of this reed (*Iliad* xi.), and the tent of Achilles was thatched with its leaves. [D.M.]

**ARVORE DE PAINA.** A Brazilian name of *Chorisia speciosa*.

**ASA DULCIS.** A drug held in high repute among the ancients, supposed to be the produce of *Thapsia garganica*.

**ASAFETIDA.** A drug formed of the concreted milky juice of *Narthex*, and of various species of *Ferula*.

**ASAGRÆA.** A Mexican genus of plants belonging to the Colchicum family, *Melanthaceæ*. The single species of this genus, *A. officinalis*, furnishes the Cebadilla seeds from which the alkaline poison veratrine

is prepared. The plant is bulbous, with long linear grass-like leaves, and a long bractless cluster of flowers: which have a six-parted perianth; six stamens, three shorter than the remainder; anthers heart-shaped, becoming shield-shaped, and bursting vertically; and fruit consisting of three lance-shaped pointed follicles, of thin papery consistence, and containing a number of winged seeds. The seeds, called Cebadilla seeds, were formerly used to destroy vermin, but are now employed in the preparation of veratria, an alkaline substance, of a powerfully irritant poisonous nature, occasionally made use of in neuralgia and rheumatic affections. It has been given internally, but from its doubtful action and dangerous nature, it is now rarely if ever employed. [M. T. M.]

**ASARABACCA.** The common name for *Asarum*.

**ASARUM.** A genus of the order *Aristolochiaceæ*, known by its bell-shaped three-cleft perianth, twelve stamens inserted at the base of the style, and with the connective of the anthers prolonged into an awl-shaped process. The fruit is a six-celled capsule, surmounted by the persistent limb of the calyx. The species of this genus are dispersed over Europe, and the temperate parts of Asia, and North America.

*A. europæum* is the Asarabacca of herbals; it is said to be found wild in Westmoreland and other places in the north of England. It is a low growing plant, with a creeping rootstock, from which proceed a number of roots, and also two rounded kidney-shaped stalked leaves; between them is placed the dull brownish flower. The roots and leaves are acrid and somewhat aromatic; they contain a volatile oil, a bitter matter, and a substance like camphor. Asarabacca was formerly used as a purgative and emetic, and also to promote sneezing, but it is now rarely used, having been supplanted by safer and more certain remedies. *A. canadense* is sometimes met with in gardens; it greatly resembles the European plant, but has larger leaves provided with a short spine. [M. T. M.]

**ASARINÆÆ.** A synonym of *Aristolochiaceæ*.

**ASCARINA.** a genus of *Chloranthaceæ*, founded by Forster on a single species from the Society Islands. It is a tree with opposite, petiolate, and serrated leaves. The flowers are dioecious and unibracteate, on lax spikes. The male flower consists of a single stamen with a short filament, and a large oblong quadriloculate anther. The ovary is globular-truncate, one-celled, and one-seeded. The stigma is sessile, depressed, and obsoletely three-lobed. [W. G.]

**ASCENDING.** Directed upwards: as the stem, which is the ascending axis. Rising upwards with a curve, from the horizontal to a vertical position: as many stems. Simply rising upwards.

**ASCI.** The name of the fruit-bearing cells in the important division of *Fungi*, called *Ascomycetes*. These may be thread-shaped, cylindrical like little sausages, clavate, or subglobose. In the latter case they are mostly few in number, and are occasionally reduced to one in each cyst or perithectum, as in *Sphaerotheca*, to which genus belongs the felted mildew of Rose-leaves and the Hop mildew. [M. J. B.]

The term *Asci* is also applied to spore-cases, consisting of a long or roundish cell containing spores. These are characteristic of lichens.

**ASCIDIUM.** A pitcher; various modifications of leaves containing, or capable of holding fluid, such as are found in *Sarracenia*, *Nepenthes*, *Cephalotus*, or even *Utricularia*.

**ASCLEPIADACEÆ.** (*Asclepiadæa*, *Asclepiada*, *Apocynæ* in part.) Among monopetalous Exogens with a superior ovary, the very large natural order which bears this name is known by its pollen being collected in the form of waxy masses or bags, derived from the separable inner lining of the anther cells; and by the fruit consisting most commonly of a pair of divaricating follicles. The species differ from *Apocynaceæ* or Dogbanes, in the peculiar structure of the staminal apparatus: the stamens in the latter order being distinct, the pollen powdery, the stigma not particularly dilated, and all these parts distinct the one from the other. But in *Asclepiadæa* the whole of the sexual apparatus is consolidated into a single body, the centre of which is occupied by a broad disk-like stigma, and the grains of pollen cohere in the shape of waxy bodies attached finally to the five corners of this stigma, to which they adhere by the intervention of peculiar glands.

Fully 1000 species are known, for the most part inhabiting the tropics of the Old and New Worlds. Two genera only are found in northern latitudes, one of which, *Asclepias*, has many species, and is confined apparently to North America; the other, *Cynanchum*, is remarkable for extending from 50° north latitude to 33° south latitude. *A. Stapelia* is found in Sicily. They vary extremely in appearance; many being leafless succulents, like *Stapelia*, others, and they are the more numerous, consisting of twiners, like *Hoya*; while another portion consists of upright herbaceous plants, such as *Asclepias* and *Vincetoxicum*; a few are tropical trees. As a general rule the species are poisonous; an acrid milk which pervades all their parts being eminently emetic and purgative.

The genera *Stapelia*, *Hoya*, *Asclepias*, *Vincetoxicum*, *Ceropegia*, *Periploca*, are good examples of the order. The manner in which the ovules of these plants are fertilised by the pollen is among the most curious phenomena known in plants. Instead of the grains of pollen falling on a viscid stigmatic surface, and then producing tubes of impregnation, the tubes are formed inside the pollen bags, whence

they ultimately find their way by a spontaneous emission, and reach the surface of the stigma without being projected upon it, conducted by some inherent vital power. For a full account of this extraordinary fact, see *Lindley's Introduction to Botany*, 4th edition.

**ASCLEPIAS.** From this genus the order *Asclepiadaceæ* takes its name. Its characters are as follow:—The corolla consists of five petals, bent downwards towards the stalk; within the petals are five curious boat-shaped processes or cups, forming what is called the coronet, and from each of these cups a curved horn-like body projects; within these are five stamens, whose filaments are united into a pentangular tube bearing five anthers, which adhere to the five-angled stigma; the pollen is also remarkable in being aggregated into two separate parcels, suspended on two threads from a sort of gland, but this is a peculiarity not confined to the plants of this genus: the fruit consists of a pair of follicles, which opening, disclose a number of seeds provided with a tuft of glossy silk-like hairs.

The genus consists of herbaceous plants with a milky juice, and which are for the most part natives of America. Several species are cultivated for the sake of their showy flowers. All of them are more or less poisonous. *A. curassavica* is employed in the West Indies as an emetic, and goes by the name of *Ipecacuanha*: the drug truly so named, however, is derived from a very different plant; see *CERHÆLIA*. *A. tuberosa*, the Butterfly-weed, has mild, purgative properties, and promotes perspiration and expectoration. *A. syriaca*, a plant misnamed, as it is a native of America and Canada, is frequently to be met with in gardens; its dull red flowers are very fragrant, and the young shoots are eaten as asparagus in Canada, where a sort of sugar is also prepared from the flowers, while the silk-like down of the seeds is employed to stuff pillows. Some of the species furnish excellent fibre, which is woven into muslins, and in certain parts of India is made into paper. Some one of the species of *Asclepias* is thought to be the Soma plant so often alluded to as an object of prayer and praise by the ancient natives of India, in the Sanskrit Vedas, which some place so far back as twenty centuries B.C. The bruised stem and leaves of the Soma plant yield a juice which, by standing, ferments into an intoxicating liquor, which is supposed to gratify the gods, and animate them to extraordinary exploits. The elevation of the plant to the rank of a deity can only have originated in a stage of semi-barbarism in the same way as we can imagine that ardent spirits might have won the adoration of the North American Indians when first introduced among them. See Max Müller's *History of Sanskrit Literature*. [M. T. M.]

**ASCOBOLUS.** A genus of *ascomycetous Fungi*, distinguished from *Peziza* by its shooting out its asci when mature. The species grow almost exclusively on the

dung of various animals. The sporidia are often of a beautiful colour and form exquisite objects under the microscope. Few fungi are more common than *A. furva-cus*, on old cow-dung. There are, however, a great many other species, varying much in colour and sculpture. Several have been detected in this country, and it is quite certain that the number will be much increased on closer investigation. [M. J. B.]

**ASCOMYCES.** A small genus of *Fungi* of the most simple construction, remarkable principally for the effect they have upon the plants upon which they are developed. The whole plant consists of a stratum of club-shaped cells filled with sporidia, with scarcely any filamentous or cellular base, developed in the shape of a white powder on the surface of the leaves, which are generally swollen and distorted, as is especially the case with blistered peach-leaves, when attacked by *Ascomyces deformans*. The asci are either accompanied by naked spores which sprout like the cells of yeast, or else the sporidia, when set free, are, propagated after the same fashion. The genus occurs on the leaves of trees, or sometimes of herbaceous plants, as *Tridentia europæa*. The most obvious examples besides those mentioned above are the *Ascomyces* of the walnut and pear, which trees are, however, far less deformed by it than the peach. As regards Peach blight, still in attributing it to sudden checks or aphides, but M. Tulane, in a communication to the French Academy, has confirmed Mr Berkeley's report referring the fungus which produces it to the genus *Taphria*. [M. J. B.]

**ASCOMYCETES.** A large division of *Fungi* distinguished by their fruit being contained in hyaline sacs (asci), and not situated at the top of certain privileged cells, as in the mushrooms and allied *Fungi*. The asci are placed parallel to each other, barren threads or sacs intervening, and are packed into a thin stratum, which equally with the fruitifying stratum of mushrooms is called the hymenium. This may be entirely exposed, or may be included in an especial organ called a perithecium. The asci are for the most part colourless, and vary from mere threads to globose sacs. The sporidia or fruitifying bodies which they contain are generally definite in number and multiples of two. Their most usual number is eight, but when they are very large these are reduced to four or two, or even one; and in other cases their number is greatly increased, so as in particular instances to be indefinite as far as our powers of observation go. In a particular condition a large proportion of these fungi produce also naked spores on distinct points, and occasionally naked spores and asci are produced upon the same hymenium. The distinction from sporiferous *fungi* is not therefore as definite as might strictly be approached.

distinguishable. It is said that asci have been lately found on the gills of one at least

of the higher fungi, *Agaricus melleus*, which is largely consumed abroad under the title of hallimasch, though justly neglected here. This, however, wants confirmation, and an assurance that some parasite is not in question. Some of the moulds again produce fruit containing a single spore, or a number of asci; but whether these moulds are true allies of the *Ascomyces* or not is at present doubtful. The *Morel* is one of the most familiar examples of the division, and one of the most highly organised. The Truffle belongs to the same division, though so different at first sight from its near allies. [M. J. B.]

**ASCOMIOTA.** A genus of vesicular Moulds (*Phycomyces*) differing from *Morel* principally in the head being at length spread and hanging over the top of the stem like a cap or bonnet. The Bread-mould belongs to this genus, and there are one or two more species of some consequence. A singular fact about some of the species is that the fruit upon the sides of the stem is different from that at the apex, retaining its globular form, and containing sporidia of a different size. *Asceporium elegans* is a most beautiful object, from the repeated and regular forked branching of the lateral threads, each division of which is terminated by a fertile vesicle. The Bread-mould is easily cultivated, and the whole development of the plant in consequence readily traced. sive cultivated on rice paste under a bell glass, and are interesting objects of study. [M. J. B.]

**ASCYRUM.** A genus of St. John's wort family (*Hypericaceæ*), numbering five species, all of them American, with a distribution from the N. United States southwards to N. Grenada. All the species have been cultivated in Britain, and one of them (*A. Cruz Andææ*) is called St. Andrew's Cross, from the circumstance of the four pale yellow petals approaching each other in pairs, so that they appear like a cross with equal arms. Collectively, they are called St. Peter's worts.

The species are all undershrubs, resembling the St. John's worts in general appearance, having opposite sessile leaves, sprinkled below with black dots, and large terminal yellow flowers, singly or three together. The genus is characterised by the tetramerous (four part) arrangement of the calyx and corolla; the two exterior sepals much larger than the inner; the deciduous petals cruciate; the stamens indefinite; the ovary ovoid, one-celled, two to four lobed, with as many styles, and numerous ovules; and the capsule enveloped in the enlarged calyx. [W. C.]

**ASERÖE.** A genus of phalloid *Fungi*, distinguished by the blind rays of the receptacle. The species, which may probably

fresh. They are confined to the islands of the southern hemisphere. The genus de-

Asperde pentactina.

minds more especial notice here, as one of the species appeared in great perfection some years since in one of the stores at Kew. [M. J. B.]

**ASEXUAL PLANTS.** This term was once applied to Cryptogams, but since two discoveries which have been made during the last thirty years, it is no more applicable to them than to Phanogams. Sexual organs have now been discovered in every branch of cryptogams. Amongst *Fungi* alone they are still obscure in several divisions, but if such genera as *Leptomitris* really belong to *Fungi*, of which there is little doubt, there is even among them the same type as amongst the higher cryptogams.

It is, moreover, singular that the impregnation of cryptogams comes nearer the type of that in animals than in phanogams. Their spermatozooids resemble closely those of animals, and indeed are often more complicated. Amongst *Fungi* alone, and lichens, which nearly approach *Fungi*, they are mere cells, without motion, analogous to pollen-grains, though they do not germinate like them, at least, so far as has been observed at present. [M. J. B.]

**ASH.** The common name for *Fraxinus*. —, **BITTER.** A West Indian name for *Simarouba excelsa*. —, **CAPE.** *Ekebergia capensis*. —, **HOOP.** *Celtis crassifolia*. —, **MANNA**, or **FLOWERING.** *Orius europæa*. —, **MOUNTAIN.** The Rowan tree, *Pyrus Aucuparia*. —, **POISON.** *Rhus venenatum*. —, **PRICKLY.** *Xanthoxylon fraxinæum*. —, **RED.** *Alphitonia excelsa*.

**ASH-WEED.** An old English name for *Epipodium Podagraria*.

**ASPALATHE.** (Fr.) *Caragana frutescens*.

**ASPALATHUS.** A large genus of S. African shrubs or under-shrubs belonging to the Pen-flowered tribe of the Leguminous family. Their leaves are commonly heath-like, often three together (ternate), or sometimes tufted, that is, a number of additional small leaves grow from nearly the same point. The flowers are terminal, racemed, or spiked, and generally yellow, but sometimes bluish purple, red, or white. About 150 species are known, many of them not unlike dwarf furze bushes. [A. A. B.]

**ASPARAGUS** belongs to the natural order *Liliaceæ*, and represents the sub-order *Asparageæ*, which consists of lilies with succulent fruit. The genus includes many species, but only one is cultivated for use, the Common Asparagus, *A. officinalis*, so well known for its powerful diuretic properties, which are ascribed to the presence of a peculiar principle called *asparagin*. See Lindley's *Vegetable Kingdom*, p. 205. Some of the species are ornamental creepers, *A. asiaticus* and *A. racemosus* are common in hilly jungles of Western India.

The Common Asparagus is a native of several places in Britain near the sea; such as the Isle of Portland, and Kynance Cove, near the Lizard, Cornwall. In the southern parts of Russia and Poland the waste steppes are covered with this plant, which is there eaten by horses and cattle as grass. It is also common in Greece, and was formerly much esteemed as a vegetable by the Greeks and Romans. It appears to have been cultivated in the time of Cato the Elder, 200 years B.C.; and Pliny mentions a sort that grew in his time near Ravenna, of which three heads would weigh a pound.

In this country Asparagus is reckoned among the oldest and most delicate of our culinary vegetables; and in its cultivated state the whole plant has a very graceful appearance. It is noticed by Gerard in 1597; and in 1670 forced Asparagus was supplied to the London market. At Mortlake, Battersea, and other places near London, where the soil is suitable, Asparagus is extensively cultivated, and by skilful management is brought to a higher degree of perfection, perhaps, than in any other part of the world. The part of the plant which is used is about six or eight inches of the young shoot, which is considered to be fit for cutting when it has emerged two or three inches out of the ground, and has a firm, compact, roundish point, of a fine green colour, slightly tinged with purple. In preparing Asparagus for table, its delicate flavour is rather deteriorated than improved by the additions which skilful cooks deem necessary for it and other vegetables. It is usually boiled and served alone with melted butter and salt, or on toasted bread with white sauce; and the smallest heads are sometimes cut into small pieces and served as a substitute for green peas. Its virtues are well known; as a diuretic it is unequalled; and for those of sedentary habits who suffer from symptoms of gravel, it

has been found very beneficial, as well as in cases of dropsy.

Prussian *Asparagus*, which is brought to the markets in Bath, is not a species of *Asparagus* at all, but consists of the spikes, when about 8 inches long, of *Ornithogalum pyrenaicum*, which grows abundantly enough in hedges and pastures in that locality, to be worth gathering for sale. [W. B. B.]

**ASPASIA.** Under this name are collected a few species of epiphytal orchids of the Vandeeus sub-order, with a lip half united to the column. They have broad oval thin pseudobulbs, and flowers mottled with purple on a violet ground. The most important species is *A. epidendroides*, a plant from Central America. The other species are from the tropics of the same continent.

**ASPEN, or ASP.** *Populus tremula*.

**ASPERGE.** (Fr.) *Asparagus officinalis*.

**ASPERGILLUS.** A genus of filamentous moulds, characterised by the hyaline or brightly-coloured jointed thread being swollen at the apex, and there studded with radiating cells, each of which produces a necklace of spores. The most common species, *A. glaucus*, distinguished by its globose echinulate spores, is one of the *Fungi* which produce the well-known blue mould, and whose spores form occasionally a part, with other common species, of the substance called yeast. It is distinguished from the genus *Rhizotrichum*, formerly associated with it, by the fertile radiating cells, which in *Rhizotrichum* are replaced by a few apicules. There is some reason to believe that there is a second form of fruit in *Aspergillus*, which constitutes the genus *Eurotium*, but this requires confirmation. [M. J. B.]

**ASPERIFOLIÆ.** An old name for what are now called Borageworts, or *Boraginaceæ*, derived from the remarkable roughness of the leaves of the greater part of the species.

**ASPERUGO.** A genus of *Boraginaceæ*, consisting of a single species, *A. procumbens*, which occurs in Britain as well as the whole of Europe and a great part of Central Asia. It is an annual plant with trailing dichotomous stems, which, as well as the obovate leaves, are rough with curved bristles; the flowers are very small, bluish-purple. The calyx is curious; it enlarges as the fruit ripens, and takes the form of two large jagged valves, which are triangular and marked with prominent veins; these valves are applied flat to each other, and enclose the fruit, which has the structure common to the order. [J. T. S.]

**ASPERTULA.** A family of *Galiaceæ* herbs, with square stems, whorled leaves and four-cleft flowers, which are either pure white, white tinged with purple externally, or more rarely blue or yellow. Many of the species are ornamental, and well fitted by their habit for the decoration of rock-work. *A. odorata*, Woodruff or

Woodrrow (so called from the resemblance between its whorled leaves and the rowel of a spur), is a common woodland plant, conspicuous in May and June by its brilliantly white flowers, and at other seasons by its bright green leaves, arranged in a star-like form round the stem. The flowers are sweet-scented, but the plant derives its name from the fragrance of its leaves. This is not perceptible while the herbage is fresh, but after being gathered a short time it gives out the perfume of new hay, and it retains this property for years. Woodruff is a useful plant in shrubberies, increasing rapidly and thriving under the shade of most trees, even the beech. It is used in Germany to impart a flavour to some of the Rhine wines. *A. cynanchica*, a small trailing plant with slender stems, very narrow leaves, four in a whorl, and small white flowers delicately tinged with pink, occurs on chalky downs in many parts of Britain. It owes its specific name, and its popular name Quinsy-wort, to its supposed virtues in curing quinsy. In the time of Gerard, *A. arvensis*, a species with blue flowers, grew in many places of Essex and divers other parts, in sandie ground. It was also found during the present century in a slate-quarry in Devonshire, but has disappeared. Most of the foreign species are hardy, and may be raised from seed. [C. A. J.]

**ASTHODEL.** *Asthodelus*. —, BOG, or LANCASHIRE. *Narthecium ossifragum*. —, FALSE. An American name for *Toxicaria*. —, SCOTCH. *Toxicaria palustris*.

**ASTHODELUS.** The *Asthodelus*. A genus of *Liliaceæ*, distinguished by having a six-leaved equal spreading perianth; six hypogynous stamens, of which the alternate ones are shorter, the filaments declinate; a filiform or subclavate style, with a capitate three-lobed stigma; a three-celled ovary, with three collateral ovules in each cell. The species are perennial herbs of Southern Europe, with fleshy, fasciculated roots; radical, subulate, triquetrous, or linear-lanceolate leaves; and a simple or branched scape bearing the white flowers in close racemes. There are several species. *A. albus* is a common garden plant, formerly called King's Spear; and this, and *A. ramosus*, which is probably only a branched variety of it, are very ornamental plants. It is stated on the authority of Symonds to cover large tracts of land in Apulia, an ancient province of Italy, and to afford good nourishment to sheep. [T. M.]

**ASPHYXIA.** Plants, like animals, require free access to atmospheric air, and if this is impeded, or the air is loaded with noxious gases, a greater or less degree of mischief is sure to follow. Death may not be the immediate consequence, but the tissues may be so impaired that there is only a short respite. The communication between these tissues is carried on in phænogams, and many cryptogams by means of the stomates. If, therefore, these

are clogged up, the proper degree of attraction cannot take place, and since the same apertures are the safety-valves for the discharge of superabundant moisture or gases which have performed their office, the whole system becomes gorged, and the proper functions impeded. In such cases a true asphyxia or suffocation takes place; and the same effect may be produced by the air-passages being filled with gummy matter, or their apertures covered by parasitic fungi, as *Antennaria*, *Cynoditum*, *Cladospodium*, &c. Plants may also be drowned by a few days' immersion in water, though in some instances there is a provision by which such an effect is altogether prevented. [M. J. D.]

ASPIO. (Fr.) *Lavandula Spica*.

ASPIDIEÆ. A section of polypodiaceous Ferns, in which the sori are punctiform, or dot-like, and covered either by reniform or peltate indusia. [T. M.]

ASPIDISTRA. A genus of *Liliaceæ* found in China and Japan. They are stemless glabrous herbs, with oblong-lanceolate striate leaves, and radical one-flowered peduncles, bearing a single dull purple flower. The perianth is bell-shaped, six to eight cleft, with spreading segments; the stamens six to eight, inserted in the tube of the perianth; the ovary small, cylindrical, three to four celled, with two ovules in each cell; the style short, thick, continuous with the ovary, terminated by a large discoid, radiate, lobed stigma. Three or four species are known. [T. M.]

ASPIDIUM. The name formerly given to a group of polypodiaceous Ferns, including all those in which the dot-like or punctiform sori were covered by a roundish cover or indusium. In this sense it is synonymous with the modern section *Aspidieæ*. It is now, however, generally divided into a greater or lesser number of genera, according to the views of individual pteridologists. The smallest amount of division is adopted by those who separate the group into two, having the indusia respectively peltate or reniform, the first being then called *Aspidium*, and the second *Nephrodium*. Those who subdivide more extensively, and separate the free-veined from the net-veined species, restrict the name to a few typical kinds having the indusium orbicular and peltate, and the veins of the fronds compoundly reticulated, with free included veinlets, which are divaricate or variously directed. Thus limited it comprises about a dozen species, with as many more doubtful ones, chiefly found in India and the east, but also occurring in South America and the West Indian Islands. The majority of the species are strong-growing pinnate ferns, with the pinnae sometimes lobed. The typical *A. trifoliatum* is sometimes seen cordate and undivided, a stunted condition, caused probably by the depressing influences under which the plants are grown; sometimes three-leaved, which seems to have been the form originally described;

and sometimes decidedly pinnate, with the pinnae more or less deeply lobed, all these forms being sufficiently developed to become fertile. These facts clearly show the variableness to which the species of ferns are liable. *A. singaporianum*, a simple-fronded species, has the fronds very remarkably narrowed at the base, and is furnished with very numerous evenly arranged sori. [T. M.]

ASPIDOSPERMA. A genus of *Apocynaceæ*, consisting of about twenty-five species of trees, from tropical America. The leaves are alternate, and mostly entire. The flowers are small and arranged in solitary or numerous dichotomously-branched cymes, at the ends of the branches. The calyx is five-partite; the corolla is hypogynous, sub-infundibuliform and five-lobed; the five included stamens are inserted in the middle of the corolla tube, and bear ovate sub-sessile anthers; there are two ovaries, with many ovules attached to the ventral suture. The fruit is a double, rarely a single follicle, compound, obovate, and woody, with numerous membranaceous seeds. The wood of this genus is valuable. *A. excelsum*, called by the colonists Paddle-wood, is remarkable for its singularly fluted trunk, composed of solid projecting radii, which the Indians use as ready-made planks. [W. C.]

ASPLENIDICTION. A synonyme of *Hemidictyum*, a genus of large growing asplenium-like Ferns. [T. M.]

ASPLENIEÆ. A section of polypodiaceous Ferns, in which the simple linear or oblong sori are parallel with the veins, and oblique to the midrib, produced on one side of the vein, and covered by indusia of the same form. The modern group, *Aspleniceæ*, is nearly synonymous with the genus *Asplenium* of the older and some modern writers. [T. M.]

ASPLENIUM. A genus of polypodiaceous ferns established by Linnæus, and, as originally defined, synonymous with the modern group *Aspleniceæ*, including the *Scolopendrieæ*, and *Diplazieæ*. In this sense it included all the ferns with lines of fructification lying parallel, or nearly so, on the disk of the frond (not marginal). The group is now considerably subdivided, and the name *Asplenium* restricted to those species in which the veins of the frond are free, the sori are linear or oblong, and lying obliquely on the parts of the frond, and the indusia are simple and distinct. Even thus reduced it is a very extensive family, found in all parts of the world, mostly evergreens, numbering about 800 species, of which nine are natives of Great Britain. As might be anticipated in so large a family, the species are exceedingly varied, especially as to division, some being simple, others lobed, or pinnate, or bipinnate, or tripinnate, or even decomposed; and while some are delicately membranaceous in texture, others are of a stouter herbaceous character, and some are thick and leathery. *A. Adiantum nigrum*, the

**Black Maidenhair Spleenwort**, one of the commoner British species, has bipinnate fronds; another common one, *A. Trichomanes*, the common Maidenhair Spleenwort, has pinnate fronds; while *A. septentrionale*, one of the rarer native species of northern habitats, has the fronds reduced to the appearance of two or three forked rigid ribs. Some of the exotic species are very beautiful in form; and many of them are cultivated on account of their beauty in our gardens and hot-houses. Several species have the very singular property, strongly developed, of bearing little buds on their surface, from which young plants are formed even while they are retained upon the parent frond. The genus has been named *Asplenium*, or Spleenwort, on account of some supposed potency in the plants over diseases or affections of the spleen; but, as in many other instances, these virtues are both fanciful and fabulous. The principal genera, separated from *Asplenium* by modern pteridologists, are *Diplazium*, *Athyrium*, *Thamnopteris*, *Hemidictyum*, *Allanodia*, *Ceterach*, and *Callipteris*. [T. M.]

**ASSAGAY-TREE.** *Curtisia faginea*.

**ASSARACUS.** A subdivision of the genus *Narcissus*, including *N. capax* and *N. reflexus*, in which the segments of the perianth are semi-reflexed, and the coronot papilioniform, about equalling the perianth segments. [T. M.]

**ASTELIA.** A genus of sedge-like *Liliaceae*, from the Islands of the Southern Ocean, with polygonous-direction flowers, having a six-parted perianth of glaucous texture; ovary three-celled or one-celled by the incompleteness of the partitions; fruit berry-like; stem very short; leaves broadly-linear, hairy, very silky at the base. *A. alayana* has leaves three-quarters of an inch broad, and an extremely short flattened scape, crowned by a dense panicle of rather large chestnut-coloured flowers. The leaves of this species, which grows on the sand-hills of the coast of Tannanra, are edible, and are said to have a nutty flavour. [J. T. S.]

**ASTEMON.** A genus of Labiates, found in Bolivia, and related to *Colobrochia*, from which it differs in having a non-plumose calyx, and a five-lobed, not four-lobed, corolla. The calyx is tubulose-campanulate, with five subequal lanceolate acuminate teeth. The corolla tube is as long as the calyx, the limb short and nearly equally five-lobed, and the throat bearded. The stamens, described as wanting, are in reality reduced to four small distant stalkless anthers, adnate to the corolla-tube. *A. graveolens* is a shrub six to eight feet high, having an unpleasant odour; the leaves oblong-lanceolate, attenuately acute, green and smoothish above, whitish and tomentose beneath; and the flowers small, white, in a terminal panicle, which is still more densely clothed than the stems and leaves with white tomentum. [T. M.]

**ASTEPHANUS.** A genus of *Asclepiadaceae*, containing thirteen species, natives chiefly of the Cape of Good Hope and Madagascar, but found also sparingly in America. They are climbing or decumbent under-shrubs, with small opposite leaves, and interpetiolar umbels, consisting of a few small and generally white flowers. The calyx consists of five acute sepals; the corolla is campanulate and has no squamæ within the tube (the character by which this genus is distinguished from *Metastelma*). There are ten small pendulous masses of pollen. [W. C.]

**ASTER.** A well-known genus of the Composite family, numbering nearly 200 species, which are distributed sparingly over Europe, Asia, and S. America, but occur in great abundance in N. America, where three-fourths of them are indigenous. They are perennial (rarely annual) herbs with alternate and simple entire or toothed leaves, and panicle, racemed, or corymbose star-like flower-heads, having an involucre of numerous imbricated scales, enclosing many florets, the outer row strap-shaped and pistil-bearing, those in the centre tubular, and all having more or less flattened achenes crowned with a pappus of numerous capillary bristles. From their time of flowering, Asters are often called Michaelmas Daisies and Christmas Daisies, some of them continuing in flower in the open air in mild seasons up to the latter period; and for this reason they are valuable garden plants, because there are few things but themselves which flower so late in the year. The Sea-side Aster, *A. Tripolium*, is the only British species. It is a pretty plant, six inches to two feet high, with linear or lance-shaped smooth and fleshy leaves, and stems terminating in corymbs of purple-rayed flower-heads, rather more than half an inch across. It occurs pretty generally over all the British as well as European coasts. The Alpine Aster, *A. alpinus*, is the type of a small group which inhabit Alpine regions alone. It is found on the mountains of Central Europe, Asia, and N. America, growing from three inches to a foot high, the stem furnished with lance-shaped or linear leaves, one to two inches long, and terminating in a blue-rayed flower-head, one to two inches across. The remainder are mostly branching plants, from one to ten feet high, with heart-shaped, willow or heath-like leaves, and starry flower-heads, always with the central tubular florets yellow, and the rays varying from white to lilac blue or purple. There is a great sameness about many of the species, and they are most difficult to determine. We can only name as some of the more showy kinds *A. spectabilis*, *A. Nova-Angliae*, *A. versicolor*, and *A. turbinellus*, all North American; *A. sikkimensis*, from the Sikkim Himalaya and the Italian Star-wort, *A. Amatus*, found in the South of Europe. [A. B.]

**ASTER, CAPE.** *Agathaea amelloides*.

CHINA. *Callistephus chinensis*. — GOLD-EN. A common name for *Chrysopsis*. — WHITE-TOPPED. An American name for *Leucocorypha*.

**ASTERACEÆ.** (*Compositæ*, *Synanthereæ*.) This is the largest natural order of plants, the species occurring in all parts of the world, and in all places, and forming a total equal to about a tenth of the whole vegetable kingdom. They are recognised by their monopetalous flowers, growing in close heads (*capitula*), and having at once an inferior one-celled ovary, and stamens whose anthers cohere in a tube (i.e. are synergensous). De Candolle states as the result of his examination of their natural habit, that out of 8,523, 1,229 were annuals, 243 biennials, 2,491 perennials, 2,264 under-shrubs from 1 to 3 feet high, 380 shrubs from 4 to 15 feet high, 72 small trees, 4 large trees above 25 feet high, 81 woody plants, 126 twiners or climbers, and 1,201, about which nothing certain could be ascertained. According to Mr. Bentham the species are nearly equally divided between the New and the Old World, there being known about 430 genera with 4,700 species in the former, and 410 genera containing 4,400 species in the latter. There are about 75 genera common to the two divisions; but the identical species in the two, and those chiefly arctic or high northern, are not more than 79 out of at least 8,100. The uses of the order, real or imaginary, are very numerous and conflicting. Some are tonic and aromatic like Wormwood (*Artemisia Absinthium*, and others); or vermifuges like those other *Artemisia* known in foreign pharmacy as *Semen-contra*, or *Semen-cine*. A few are powerful rubefacients, as Pellitory of Spain (*Anacyclus Pyrethrum*), and various kinds of *Spilanthes* which excite salivation. *Arnica montana* is powerfully narcotic and acrid. Similar evil qualities belong to *Oreopis lacera*, a most venomous species, said to be no infrequent cause of fatal consequences to those who, in the South of Europe, incautiously use it as salad. Nor are *Hieracium vicosum* and *H. sabaudum* altogether free from suspicion. Some species of *Pyrethrum* have the power of driving away fleas. Many yield in abundance a bland oil when their achenes or 'seeds' are crushed: such are the Sun-flower (*Helianthus annuus*), the Til or Ram-till (*Verbesina sativa*) largely cultivated in India, and *Madia sativa*. A purgative resin is obtained from some allies of the Thistles; others, as *Aucklandia Costus*, now referred to *Apiotaxis Lappa*, have aromatic roots, and are looked upon by Orientals as aphrodisiacs. Finally, under the name of Artichoke, Succory, Scorzoneria, Endive, Salsify, and Lettuce, we have some of our most harmless and useful esculents. Botanists adopt various modes of classifying this immense mass of species; but all are subordinate to the four following capital groups, viz.:—**CINORACHÆ**: florets all ligulate; **CORYMBIFERÆ**: florets tubular in the disk; **CYRACÆÆ**:

florets all tubular, with an articulation below the stigma; **LABIATIFLORÆ**: florets bilabiate.

**ASTERANTHOS.** A genus represented by a single Brazilian shrub, whose true affinities have not yet been established, the natural order *Beisniaceæ* (provisional to some extent, and by recent authorities merged in *Myrtaceæ*), has been created to receive it, and the allied genus *Napoleona*, both possessing sufficient characters to separate them from every known family. This genus has alternate, ovate-lanceolate, entire, and shortly petiolate leaves, and solitary axillary flowers. It has a short campanulate, many-toothed calyx, adherent to the ovary, and a simple many-lobed corolla. The indefinite stamens are inserted at the base of the corolla, and have filiform filaments, and oblong anthers. The inferior ovary has a simple style, and an obtusely six-lobed stigma. [W. C.]

**ASTERE D'AFRIQUE.** (Fr.) *Agathæa amelloides*.

**ASTEROLINUM.** A genus of the Primrose family, with a single species, *A. stellatum*, found in S. Europe and Asia Minor, chiefly on the sea coast. It is a little erect or decumbent annual, one to three inches high, with opposite linear leaves, one-sixth of an inch in length, bearing in their axils single stalked minute flowers, whose greenish-white corollas are nearly hidden by the calyx. The minute corollas and few-seeded capsules are the chief distinguishing marks between this genus and *Lysimachia*, in which the plant was placed by Linnaeus with the name *Lysimachia linum-stellatum*, alluding to its flax-like leaves and starry flowers. [A. A. B.]

**ANTEROSTEMMA.** A genus of *Asclepiadaceæ*, having the following distinguishing characters: the coronet of the stamens five-lobed, fleshy, short, coloured, and cup shaped, its lobes crescent-like, or three-toothed, opposite to the anthers, which latter are terminated by a membranous crest; the pollen masses are erect. *A. repandum* is a climbing shrub inhabiting Java. [M. T. M.]

**ASTEROSTIGMA.** A genus of the family *Aracææ*, comprising one or two Brazilian species, which have a tuberous rootstock, from which arise the leaves and also the stalked spadix, encircled by a spreading purplish spathe. The male flowers are at the upper part of the spadix; the anthers open by a terminal pore. The ovaries which are placed at the lower part of the spadix surrounded by abortive stamens, are three or four-celled, each cell containing a single erect ovule. The style is short and terminated by a flattened stigma, which is divided into three or four segments, each of which is again divided into two, giving to the stigma that star-like or radiating appearance denoted by the name of the genus. [M. T. M.]

**ASTRAGALUS.** A genus of perennial

## The Treasury of Botany

plants belonging to the Papilionaceous subdivision of the Leguminous family. They have woody roots; unequally pinnate leaves; flowers in axillary clusters; a tubular or bell-shaped calyx, with five teeth; a corolla with the standard larger than the wings, and a blunt keel; stamens in two parcels; a curved fruit or legume, divided into two cavities by the projection inwards of the hinder wall of the fruit. They have compound leaves, <sup>terminating entire</sup> branches. There

species distributed all over Europe, Central and Northern Asia, North America, the Andes, penetrating into the Arctic regions, ascending high Alpine summits, and abundant in the hot rocky districts of the Mediterranean region. A great number are cultivated in this country, and three species are found wild. One, *A. glycyphyllos*, has long stems, trailing on the ground like those of a pea, large leaves, and yellow flowers. The other two are humble plants with small leaves: *A. hypoglottis* has purplish flowers and erect pods, rather longer than the calyx; and *A. alpinus*, which is only found in the Clova mountains, has pendulous pods, which are three times the length of the calyx.

*Astragalus gumifer.*

The gum-like substance called Tragacanth is the produce of *Astragalus gumifer*, and other species growing in Persia, Asia Minor, Kurdistan, etc. The gum exudes naturally from the bark in the same way that gum exudes from the bark of cherry or plum trees. The seeds of *Astragalus baccatus* are used in place of, and sometimes mixed with, coffee; the plant is cultivated for these seeds in certain parts of Germany and Hungary. [M. T. M.]

**ASTRANCE.** (Fr.) *Astrantia*.

**ASTRANTIA.** A genus of Umbelliferae, native of Europe and Western Asia, con-

taining some ten or twelve species. They are perennial herbs, with black, aromatic roots, palmlobed, petiolate, radical leaves, and few generally sessile stem leaves. The umbels have a leaf-like involucre, and few umbellules consisting of many white or rose-coloured, often polygamous flowers, surrounded by a conspicuous involucre, consisting of many membranaceous, whitish or slightly-coloured leaves. The tube

of the corolla, being ... from the middle. The ... the mericarp, without vittae, has five prominent toothed juga, with smaller juga in the intervening spaces. [W. C.]

**ASTRAPÆA.** A genus of small trees, belonging to the natural family Sterculiacæ. Their leaves are alternate, stalked, cordate, and from three to five-lobed, generally hairy or viscid, and having at their base large stipules. The peduncles are axillary, long, pendulous or erect, bearing on their apex an umbel of large sessile flowers, enclosed in a leafy involucre. *A. Wallichii* has large leaves and bright red flowers, nearly as large as those of some rhododendrons; the leaves are sometimes one and a half feet long, and of the same breadth. It has long been in cultivation in England, is an elegant plant, and the drooping heads of flowers give it a peculiar appearance. *A. viscosa* has erect peduncles and much smaller flowers, which are white with a pink centre. The bark of *A. cannabina* is used in Madagascar (where all the species are found) for making cords. [A. A. B.]

**ASTROLOMA.** A genus of *Euphorbiaceæ*, containing eight species, natives of New Holland and Tasmania. They are low under-shrubs, often prostrate, with crowded alternate linear or obovate-lanceolate and mucronate leaves; and with solitary axillary flowers of a reddish colour. The calyx is five-partite, with four or more bracteoles. The corolla is hypogynous and tubular, distended above the middle, and with a short five-cleft limb; it has five bundles of hairs in the inside near its base. There are five included stamens, with linear filaments, and oblong simple anthers. The disk is hypogynous and cyathiform. The ovary is five-celled, with one ovule in each cell; the style is simple, and the stigma capitate. The fruit is a drupe, composed almost entirely of solid putamen with five cells. [W. C.]

**ASTRONIA.** A genus of Melastomaceæ trees, from the Moluccas, with the habit of *Melastoma*. The leaves are opposite, long-stalked, three-ribbed, oblong acuminate; the flowers small, purplish, in terminal panicles; petals five or six; stamens ten or twelve; fruit a three or four-celled many-seeded berry, branches four-angled, and, as well as the peduncles and calyx, with dark scales. *A. papetaria* has subacid leaves, which are cooked as a sauce to fish. [J. T. S.]

**ASTROPHEA.** A section of the genus *Passiflora*, characterised by the absence of cirri and involucre, and by its ten parted calyx and five stamens. The species are South American trees. [W. C.]

**ASUL.** The Arabic name of *Tamarix orientalis*. Also an Indian name for *Tamarix foras*, a nut-gall tree.

**ASYSTASIA.** A genus of Acanthaceous plants, natives of the East Indies, the warmer and temperate parts of Asia and Africa. They are herbaceous, or shrub-like, with slender branches; axillary or terminal clusters of flowers, which are blue or yellowish, and handsome, with a regularly five-parted calyx, a somewhat funnel-shaped corolla, with a limb divided into five nearly equal segments; stamens four, united in pairs at their base; anthers two-celled; cells parallel, thickened or provided with an appendage at the base; stigma capitate two-lobed. Capsule compressed, slender, and seedless below; above somewhat four-cornered, two-celled, four-seeded. Seeds with a prominent angle at the base. [M. T. M.]

**ATACCIA.** A genus of the small order *Tuccaceae*. The tube of the perianth is in these plants connate with the ovary, and the six-parted limb has the inner segment larger reflexed and persistent. The flowers contain six stamens, inserted at the base of the segments of the limb, and having broad filaments concave above; the style is short, thick, three-furrowed, with a capitate three-lobed stigma; the ovary is sub-three-celled, containing numerous ovules, and becomes a semi-three-celled many-seeded berry. There are few more remarkable-looking plants than *A. cristata*, sometimes met with in gardens under the incorrect name of *Tucca integrifolia*. It has a short conical underground caudex, or rhizome, and produces from this caudex three or four large oblong acuminate purplish-green stalked leaves. The scape is about as long as the leaves, erect, stout, angled, dark purple, terminated by a large four-leaved involucre, of which the two outer leaflets are dark purple, opposite, sessile, and spreading; and the two inner much larger, placed side by side, green with a deep purple base and stalk. The numerous flowers form a drooping one-sided umbel; the perianth dark purple, with a turbinate six-angled tube, and a six-parted limb suddenly reflexed. The segments arranged in an outer smaller, and an inner larger series, the rim of the mouth forming a crenated ring. This plant is a native of the islands of the Malayan Archipelago, and one or two other species are Indian. Of no known utility, but highly curious in structure. [T. M.]

**ATALANTIA.** A genus of Aurantiaceous plants, known by their undivided leaves, few stamens, united below into a tube, and one ovule in each cell of the ovary. The trees and shrubs of this genus are natives of the East Indies. The wood

of *A. monophylla*, a native of Coromandel, furnishes a heavy closely grained yellow wood, suitable for cabinet work. The fruit is called WIM Lime by the Hindoos. [M. T. M.]

**ATAZIA.** A genus of Grasses of the tribe *Phalarideae*, with the inflorescence in thyrsoid panicles; spikelets three flowered; inferior flower male, with two pales, intermediate neuter with one pale, and the terminal hermaphrodite, triandrous; glumes unequal. Steudel describes four species, none of which are British. *A. Horridula*, a native of Java, has the peculiar property of emitting, when bruised, a similar odour to that given out by the English sweet scented vernal grass, which is supposed to result from the presence of a portion of benzoic acid (?) in their tissues. This fragrant principle is called coumarin. [D. M.]

**ATCHAR or ACHAR.** A condiment prepared from *Bambusa arundinaria*.

**ATHANASIA.** A genus of yellow-flowered Composites, consisting chiefly of greenhouse evergreens of shrubby habit, from Southern Africa, and a single annual species from Barbary, the *A. annua*, formerly much more cultivated than at present on account of the long duration of its flowers. It attains a height of about two feet or more, with diffusely branched furrowed stems; pinnatifid fleshy foliage, with linear segments; and corymba of clustered flower-heads on long foot-stalks, the florets being all tubular. Though of somewhat rambling habit, the small amount of care it requires, and the lasting character of its blossoms, render it deserving of some attention. The cut flowers preserve their freshness for a long period. The genus derives its name from the Greek *Ἀθάνατος*, signifying immortality, in allusion to the unfading nature of its flowers. [W. T.]

**ATHERANDRA.** A genus of *Asclepiadaceae*, containing two species, from the Moluccas; climbing shrubs, with slender branches, ovate and opposite leaves, and few flowered axillary cymes. The calyx consists of five lanceolate sepals, and the corolla of as many linear-lanceolate lobes. The filaments are free above, and the anthers are adpressed to the stigma, and more or less connate among themselves. There are twenty granular masses of pollen. [W. O.]

**ATHEROSPERMAEAE.** (*Plume Nutmegs*.) A small natural order of trees from Australia and Chili, deriving their English name from their aromatic nuts, being furnished with a permanent style, clothed with long hairs. Only three genera are known: *Atherosperma*, *Laurelia*, and *Doryphora*, which see. Their flowers are insignificant. They are placed by Lindley in the Menispermal alliance of diclinous Exogens.

**ATHEROSPERMA.** A genus of *Atherospermaceae*, containing a single species from New Holland. It is an aromatic tree with four-cornered branches, opposite leaves,

and pedicellate axillary solitary flowers, with two deciduous bracteoles. The flowers are monocious. The male flower is campanulate, with a very short tube, and eight lobes; and the ten to twelve fertile stamens are mixed with scale-shaped barren ones. The calyx of the female flower is the same as in the male; the ovaries numerous, sessile, and distinct, with one cell and one ovule. [W. C.]

**ATHROTAXIS.** See *Arthrotaxis*.

**ATHYRIUM.** A genus of polypodiaceous Ferns of the section *Aspleniceæ*, closely allied to *Asplenium*, with which some have united it. It agrees with that genus in the peculiarities of having free veins, and simple distinct indusia; but the sori are lunate or more or less horse-shoe-formed (hippocrepiform), this distinguishing character being most strongly developed in the sori which are placed more immediately in the neighbourhood of the principal veins. The species, several in number, found in various parts of the world, are mostly deciduous in habit; and one of them, *A. Filix-ferina*, the Lady Fern, is plentiful in Great Britain, where it assumes a great variety of beautiful forms, which will be found described in Moore's *Handbook of British Ferns*, or more fully, accompanied in many instances, by figures, in the *Octavo Nature-Printed British Ferns*. The Lady Fern has bipinnate or tripartite fronds of delicate texture, and of a remarkably elegant pliny character. [T. M.]

**ATLEE GALL.** A gall nut produced abundantly by *Tamara orientalis*, which is called Atle by the Egyptians. It is filled with a deep scarlet liquid.

**ATRACTYLIS.** A genus of prickly-leaved thistle-like plants belonging to the Composite family (*Compositæ*). They are perennial or annual herbs, from three inches to one and a half foot high, with toothed or pinnatifid leaves, their margins often spiny. The flower-heads are terminal, solitary, or three to four together, having a double involucre, the scales of the external one pinnatifid and leafy, with spinous teeth, standing apart from the inner involucre, and forming, as it were, a fence round the flower head. The scales of the inner involucre are ovate or lanceolate, terminating in a spinous point. The florets are generally of a pink colour. One species is found in North China, and all the others are natives of the Mediterranean region, abounding in Algeria, and growing chiefly in "rid desert places. [A. A. B.]

**ATRAGENE.** A genus of somewhat woody-stemmed *Ranunculaceæ*, of climbing habit, differing from *Clematis* only by having petals, which, however, are small and pass gradually into stamens. The sepals are large and coloured, usually purple as in the solitary flowered species of *Clematis*; the leaves opposite, compound, ternate, the leaf-stalks twining round supporting bodies. They occur in the temperate regions of both the New and Old Continents, in the northern hemisphere.

One species, *A. alpina*, is not uncommon in gardens. [J. T. S.]

**ATRAPHAXIS.** A genus of Asiatic and Cape of Good Hope *Polygonaceæ*, forming low shrubs with rigid much-branched often splay stems, and small entire oblong leathery leaves; stipules sheathing, with a small free appendage on each side; flowers fasciculate near the end of the branches, on short peduncles; calyx coloured, four-leaved, the two inner divisions largest, conspicuously so in front (they are probably really petals); stamens six; styles two; fruit a small lens-shaped nut, included between the two large ovate deltoid calyx segments. A few species are cultivated as greenhouse plants, but their scrubby stems and small flowers present few attractions. *A. spinosa* is a dwarf hardy shrub. [J. T. S.]

**ATRIPLEX.** Orache. A genus of *Chenopodiaceæ*, with the foliage covered with a granular meanness. The Oraches are chiefly distinguished by the two bracts or small leaves, enclosing the fruit, and enlarging after flowering; they are frequently dotted with large-coloured warts, which give them a peculiar appearance. The genus possesses several species, which are very variable in form, according to soil and situation. They inhabit waste places or mud banks by the sea shore, rarely occurring inland, with the exception of the *Atriplex patula*, which accompanies arable cultivation, especially in wet sandy clays. There are five British species:—*A. patula*, of which several more or less distinct forms are described; *A. littoralis* and *A. laciniata*, sea-coast plants, the latter silvery-white all over, as if frosted; *A. portulacoides*, a shrubby much-branched species called Sea Purslane; and *A. pedunculata*, distinguished by its pedicellate fruit. [J. B.]

The Garden Orache, or Mountain Spinach (*A. hortensis*), is a tall erect-growing hardy annual, a native of Tartary, introduced in 1648. It is not much cultivated in this country, but in France, under the name of *Arroche*, it is grown to some extent for the sake of its large and somewhat succulent leaves, which are either used alone as spinach, or mixed with sorrel, for the purpose of correcting its acidity. The quality of the spinach yielded by Orache is far inferior to that of the common spinach (*Spinacia oleracea*), or even of the New Zealand spinach (*Tetragonia expansa*); but its leaves being produced abundantly during summer, it is occasionally found useful for culinary purposes. There are several varieties of this plant cultivated, but they do not differ in any other respect, excepting in the colour of their stems and leaves, which vary from pale green to a red or lurid purple, and are very ornamental. The seeds are said to be so unwholesome as to excite vomiting. See Lindley's *Vegetable Kingdom*, p. 573. [W. B. B.]

**ATRIPLICES.** A synonyme of *Chenopodiaceæ*.

**ATROPA.** A genus of plants of the natural order *Solanaceae*; or by Miers made the type of a new family called *Atropaceae*. The genus is known by its five-parted calyx; its bell-shaped corolla formed of five united petals; five stamens adhering to the lower part of the tube of the corolla, with their anthers opening by long slits; a two-celled ovary and succulent fruit, each containing several seeds.

The Deadly Nightshade (*A. Belladonna*) is found wild in Southern Europe and Western Asia, also in this country, frequently on chalky soils, and not uncommonly in the vicinity of ruins. Though the stems die down annually, they spring from a perennial rootstock, and form in summer time a bushy plant, with stalked egg-shaped entire leaves of a dull green colour, and a peculiar heavy smell. The flowers are borne on short drooping flower-stalks in the axils of the leaves, or in the forks of the stem; they have a widely-spreading bell-shaped calyx, deeply divided into five pointed segments, and a bell-shaped corolla, somewhat less than an inch in length, and of a dull purplish-brown colour, but whitish or yellowish at the lower portion (uppermost as the flower hangs on the bush). The berry is of a dark shining black colour, about the size and form of a cherry, of a sweet or mawkish taste, and placed at the bottom of the permanent spreading calyx. All parts of the plant are poisonous. It is supposed to have been the plant which produced such remarkable and fatal effects on the Roman soldiers during their retreat from the Parthians under Mark Antony, as recorded in Plutarch's life of Antony. Buchanan relates the destruction of the army of Sweno the Dane, when it invaded Scotland, by the berries of this plant. They were mixed with the drink which the Scots, according to the terms of the truce, were to supply to the Danes.

When taken in large or poisonous doses, *Belladonna* produces a peculiar form of delirium, widely-dilated pupils, great thirst and dryness of the mouth, and ultimately coma and death. The poisonous principle is an alkaloid called *atropin*, which exists in all parts of the plant, and is of a frightfully poisonous nature. *Belladonna* is much used in medicine in small doses in the shape of an extract; this and the alkaloid *atropin* are also used as an external application. *Belladonna* is employed as a sedative to allay pain and spasm, and to relieve incontinence of urine, for which purpose it has a remarkable effect. It is frequently smeared round the eye in cases where it is necessary to dilate the pupil, this being one of the peculiar effects of *Belladonna*. It is said by homœopaths to act as a preventative of scarlet fever, as the use of *Belladonna* causes dryness and redness of the throat, such as also occurs in scarlet fever; hence, on the principle of like curing like, the use of *Belladonna* is recommended for this disease. It has been recently discovered that quantities of *Belladonna*, which would seriously affect

adults, can be taken with impunity by children, and also that the action of *Belladonna* and of *Opium* are so mutually antagonistic that the one may be employed as an antidote to the other. Valuable as *Belladonna* is as a remedy, it is obvious that it should never be employed except by a duly qualified person. In cases of poisoning by *Belladonna*, the stomach-pump and emetics should be had recourse to as speedily as possible.

*Atropa Belladonna.*

The mandrake was formerly referred to this genus, but is now included in the genus *Mandragora*. [M. T. M.]

**ATROPAL.** An ovule which never alters its original position; same as *Orthotropal*.

**ATTALEA.** The name of a genus of lofty Palms, natives of tropical South America. The leaves are large and pinnate. The fruits hang in large clusters, each nut consisting of three cells, and containing as many seeds, a circumstance which serves to distinguish the genus from all its allies.

*A. funifera*, called by the Brazilians *Piassaba*, yields a fibre of much value, derived from the decaying of the cellular matter at the base of the leaf-stalks, and the consequent liberation of the fibrous portions. This fibre is much used in Brazil for the purpose of rope-making, and in this country is employed for making brooms to sweep the streets. A fibre, having the same name, is also produced from another palm called *Leopoldinia Piassaba*.

The seeds of *A. funifera* are known as *Coquillanuts*; they are three or four inches long, oval, of a rich brown colour, and very hard in texture; hence they are much used in turnery for making the handles of doors, umbrellas, &c. The seed-vessels of *A. compta*, the *Pindova* Palm of Brazil, are

eaten as a delicacy; the leaves of the same plant are used for thatching, for making hats, &c. *A. speciosa* and *A. excelsa* furnish nuts, which are burnt to dry the juice of *Siphonia elastica*, which furnishes India rubber. *A. Cohnu*, a native of Honduras, produces nuts called Cahoun nuts, which yield a valuable oil. [M. T. M.]

**ATTRAPE-MOÛCHE.** (Fr.) *Apocynum androsaemifolium*; also applied to *Arum crinitum*, *Diantha muscipula*, *Lychnis Viscaria*, and *Silene muscipula*.

**ATWISHA.** An Indian poison, supposed to be *Aconitum ferox*.

**AUBAINE ROUGE.** (Fr.) A kind of wheat.

**AUBE'PINE.** (Fr.) *Orategus Orycantha*.

**AUBERGINE.** (Fr.) *Solanum esculentum*, sometimes called *S. Melongena*.

**AUBOUR.** (Fr.) *Cytisus Laburnum*.

**AUBRIETIA.** A section of the Cruciferous genus *Farsetia*, from which it is separated by having the valves of the oval pod convex and not flattened. The outer sepals bulging at the base, and the shorter stamens with a tooth on the filaments, distinguish it from the allied genera. The species are low diffuse plants, with greyish leaves, and handsome purple flowers. *A. deltoidea*, a native of the eastern Mediterranean region, is a pretty spring-flowering plant, often introduced on rockwork, as are also *A. graeca*, *A. purpurea*, and others. [J. T. S.]

**AUCKLANDIA.** *Aptotaxis*.

**AUCUBA.** A genus of evergreen shrubs, referred to the order *Cornaceae*, and distinguished by their dioecious flowers, of which the males have a small four-toothed calyx, a four-petaled corolla, and four short stamens alternating with the petals; and the females have, instead of the stamens, an inferior one-celled ovary, surrounded by a fleshy epigynous disk, the style short thick tumid at the base, the stigma orbiculate, and the ovary containing a single ovule. The fruit is a one-seeded berry. The *Aucuba japonica* is a well-known shrub of vigorous habit, highly prized for its capability of enduring and even thriving in the atmosphere of towns and cities. It forms a dense roundish bush, furnished with large glossy leathery leaves of an elliptic form, remotely serrated, and in the original garden form conspicuously blotched with pale yellow though green-leaved forms, and others distinctly and handsomely variegated, are now becoming common. The flowers are inconspicuous, but since the introduction of the male or pollen-bearing plant, in 1861, by Mr. E. Fortune, we have been enabled to secure the beautiful coral-red berries, which are borne in profusion, and render the bushes

**AUDOUINIA.** A genus of *Bruniaceae*, containing a single species, from the Cape

of Good Hope. It is a small shrub erect branches, spirally arranged imbricate leaves, and purple flowers in a terminal oblong capitulum. The calyx tube is short and adherent to the ovary, the limb being deeply five-partite. The corolla consists of five spreading unguiculate petals. The five stamens are shorter than the petals and alternate with them. The ovary is slightly three-lobed, and three-celled, with two ovules in each cell. There is a single trigonous style, with three small papilliform stigmas. [W. C.]

**AUGEA.** An annual glabrous fleshy herb, with the aspect of a *Mesembryanthemum*, but with small inconspicuous green flowers, without petals, ten short stamens, and a ten-celled superior ovary. It forms a genus of *Zygophyllaceae*, and is a native of sandy saline wastes in the Cape Colony.

**AUGUSTIA.** A genus of Begoniads, separated by some modern botanists from *Begonia*, and consisting of succulent tuberos plants found at the Cape of Good Hope. The staminate flowers have two, the pistillate five sepals; anthers small, elliptical, lengthened into an obtuse cone; filaments long, not united; style persistent, its branches furnished with a continuous papillose band, making two spiral turns; placenta split lengthwise, their transverse section ovate-oblong; seed vessel with three nearly equal wings. There are four species known, viz.—*A. Dregei*, *A. Coffra*, *A. suffruticosa*, found at the Cape, and *A. natalensis* at Port Natal. The genus is named after Dr. August of Berlin. [J. H. B.]

**AUGUSTINIA major** (or *Bactris major* of Jacquin) is the only known representative of a genus of Palms inhabiting Venezuela and New Grenada, and bearing an edible fruit of a pleasant acid flavour. It grows from twelve to twenty feet high, and its cane-like trunks, several of which spring from the same root, form thick bushes, quite impenetrable on account of the spines with which the plant is clad. The leaves are pinnate. The inflorescence, enclosed in a double spathe, is axillary; the flowers are monœcious; and the fruit is a dark violet-coloured smooth drupe, about the size of a pigeon's egg. [B. B.]

**AULACOSPERMUM.** A genus of *Umbelliferae*, containing two species of perennial, glabrous, herbaceous plants, with bipinnate leaves, natives of Altai. The limb of the calyx is five-toothed or obsolete. The petals are ovate and entire. The fruit is ovate and slightly compressed; each mericarp has five longitudinal winged ridges, with intervening vittate furrows; the commissure is plain. [W. C.]

**AULAYA.** A genus of *Scrophulariaceae*, containing eight species, natives of the Cape of Good Hope. They are parasitic herbaceous plants, having the habit of *Orobanchæ*, with imbricate scale-like leaves, and gaudy flowers. The calyx is campanulate and five-cleft, with two bracteoles. The

tube of the corolla is clavate at the base, and inflated upwards; the limb is spreading and five-cleft. There are four included didynamous stamens, inserted in the base of the tube. The anthers have two cells, the one being perfect, ovate-acuminate, the other abortive, longer and subulate. The ovary is two-celled, and contains many ovules; and the style is terminated by a clavate involute stigma. [W. C.]

AULNE. (Fr.) *Alnus glutinosa*. — NOIR. *Rhamnus Frangula*.

AUNE. (Fr.) *Inula Helenium*.

AURANTIACEÆ. (*Aurantia*, *Citron-vorts*) The Orange, Lemon, and similar fruits, are produced by trees belonging to this natural order of the Rutal alliance. They are all bushy or woody plants, having the leaves filled with transparent oil-cysts, giving them a dotted appearance, a definite number of hypogynous stamens, and a fruit more or less pulpy. Less than 100 species are known. The various genera are almost exclusively found in the East Indies, whence they have in some cases spread over the rest of the tropics. Mention is made of a wild orange of Brazil, which has a mawkish taste, but must have been introduced. The *Skimmias*, included by Bentham and Hooker in *Toddalia*, a tribe of *Rutaceæ*, have been classed with the *Aurantiaceæ*.

AURICULA. *Primula Auricula*, a favourite garden flower.

AURICULARINI. An order of hymenomycetous *Fungi*, distinguished by the hymenium being destitute of gills, pores, prickles, or other decided prominences. In a few species of one genus only there are a few obscure folds or papillæ. The nobler species have the hymenium inferior, as in the *Mushrooms*, &c.; but as the order contains a great mass of a low condition of organisation, very many of the species are permanently glued to the substance from which they spring. But even amongst these there is a tendency to become free at the margin, and to reflect it so as to take the hymenium away from the light. Several of the species are amongst the most common of fungi. The yellow *Stereum hirsutum* grows on almost every oak log, and the purple *Stereum purpureum* on every fallen poplar. The dark Indigo-blue *Corticium caruleum*, so common on damp rotten rails, is said to be occasionally phosphorescent. The order is distinguished from the *Tremellini* by the expanded horizontal hymenium, which is, besides, more definite, and formed after the same type as that of the higher orders of the family; whereas in the *Tremellini* the fruiting cells or sporophores are of unequal length. There is, moreover, in the higher *Auricularini* a distinct pileus, while in the *Tremellini*, with the exception of *Hirniola* and *Exidia*, where there is often a distinct barren outer coat, as in *Perisia*, the whole surface, even in the highest species, bears fruit. No plant of the order is known to have any economical use. [M. J. E.]

AURICULATE. Having a pair of small round lobes or ears, as is the case with many leaves.

AURONE FEMELLE. (Fr.) *Santolina Chamæcyparissus*. — MÂLE. *Artemisia*

AVA. A kind of pepper, called *Macropiper Methysticum*. The name is also given to a spirit distilled in the Sandwich Islands from the root of a species of *Cordyline*.

AVANT-PÂQUES. (Fr.) *Tulipa sylvestris*.

AVENA. Oat grass. A genus distinguished by large membranaceous outer pales, enclosing from two to three florets, each armed with a bent more or less twisted awn.

Meadow species: *A. pubescens*, Downy Oat Grass; leaves downy, with soft hairs; a common meadow-grass in limestone pastures, which should be included in the seeds for such situations. *A. pratensis*, Narrow-leaved Oat Grass; leaves hard and rigid; a denizen of moors and poor clays. Its specific name is inappropriate as its favourite habitat is seldom worthy of the name of meadow. *A. alpina*, Great Alpine Oat Grass; a larger and coarser form than the preceding, of which it is probably a mountain variety. *A. flavescens*, Yellow Oat Grass; flowers small yellow; an upland pasture grass of considerable merit.

Agrarian species: *A. strigosa*, Bristle-pointed Oat; seeds much like those of Corn Oats, the awned inner pales with two long bristly points; occasionally met with in corn-fields, where it has probably been introduced with foreign seed. *A. sativa*, Wild Oat; awn much bent, the lower half twisted, the inner pales covered with stiff hairs. These peculiarities give the seed so much the appearance of a fly, that the rustics often make use of it in trout fishing, and as the twisted awn uncoils when it comes in contact with the water, the fish is deceived by its apparent struggling; this property of the awn has likewise caused it to be used as a hygrometer; it is a common weed in clay soils.

The two latter species have lately attracted considerable attention from their connection with agriculture. Dr. Lindler, in an article in *Morton's Cyclopaedia of Agriculture*, suggested that the cultivated Oat 'is a domesticated variety of some wild species, and may be not improbably referred to *Avena strigosa*;' but perhaps, after all, the *A. strigosa* may be but a variety of *A. sativa*, from the cultivation of which it has been shown that Cereal or crop Oats may be grown, in illustration of which we here give a short account of our own experiments.

In 1852 we sowed a plot of the seeds of *A. sativa*, collected in 1851: they grew well, but were scarcely different from the wild plant, except in a tendency to an increased plumpness of grain. The produce of this

crop was preserved throughout the winter, and sown in a different part of the garden in the spring of 1833; we repeated the process with successive crops in 1834 and 1835, in each of which we noted an increase of tendencies in the following direction: 1. a gradual decrease in the quantity of hairs on the pales; 2. a more tumid grain, in which the pales were less coarse and the awns not so strong and rigid; 3. a gradual increased development of kernel or flour. The produce again sown in 1836 had so far advanced, that we collected poor, but still decided samples of what are known as the Potato and Tartarian forms of Oat. These we have gone on improving until, in 1860, we had a quarter of an acre each of good white Tartarian and Potato Oats, as a farm crop, which had been derived from the wild example. This is the more interesting, because farmers have always stated, especially on the poor illas clays of Gloucester and Worcester, that they could not grow oats without leaving behind a quantity of wild or weed oat; and our subsequent inquiries have convinced us that shed oats in some situations do really degenerate into wild ones, and the first stage in the process of degeneration will be observed in an accession of hairs at the base of the grain, which good cereal oats never possess.

We may then view the different forms of crop Oats, as induced varieties from the *A. sativa*. In cultivation, it would appear that the best and plumpest oats are grown in North Britain; here they make a good meal, which is much used as human food, Oatmeal, 'parritch' being indeed an article of diet far more nourishing than the potato, which is the more usual food of the southern.

[J. B.]

**AVENS.** The common name for *Geum*.

**AVERRHOA.** A genus of *Oxalidaceæ*, consisting of a few small trees, originally from the Moluccas and Ceylon, but cultivated throughout India. They have evergreen alternate pinnated leaves, somewhat like those of the ash, or rather the sumach, and small purplish flowers in racemes. The fruit is like a cheikin in shape, very acid, but pleasant when made into syrup, candied, or pickled. The leaves are slightly sensitive. *A. Dilimbi*, the Blimbing, has many pairs of leaflets, and the flowers produced from the trunk. *A. Caranbola*, the Caranbola, has only from two to five pairs of leaflets, and the flowers produced from the branches. [J. T. S.]

**AVET.** (Fr.) *Abies pectinata*.

**AVICENNIA.** A genus of *Verbenaceæ*, the Vervain family. The plants here included are often called White Mangroves, and, like the true Mangroves, are found in the tidal estuaries of most tropical countries. They are small trees, with opposite evergreen leaves, which are oblong, entire, and covered beneath with a white pubescence. Their flowers are inconspicuous, and arranged in closely-packed

terminal bunches. Their roots stand out of the mud in which they grow, overarching each other in erect angled masses, and sending up asparagus-like shoots from their underground parts. *A. tomentosa* is in great reputation in Rio for tanning. The native washermen of India (dhoobies) make a preparation from the ashes of the wood, which they use in washing or cleaning cotton cloths. The green fruits boiled with butter form poultices, used in native practice. In N. S. Wales the wood is valued for stone-masons' mallets, on account of its toughness. *A. nitida* is called Courida in British Guiana. The wood is used for the foundations of buildings and underground work, on account of its power of resisting damp; exposed to the atmosphere it soon perishes. The bark is used for tanning in the W. Indies. [A. A. B.]

**AVIGNON BERRIES.** The yellow dyerberries of the Buckthorn, *Rhamnus infectoria*.

**AVOCATIER.** (Fr.) *Persea gratissima*.

**AVOINE.** (Fr.) *Avena sativa*. — **A. CHAPELET.** *Avena bulbosa*. — **DE HONGRIE.** *Avena orientalis*.

**AWL TREE.** The Indian Mulberry, *Morinda citrifolia*.

**AWL-WORT.** The common name for *Subularia*.

**AWN.** The beard of corn, or any such slender process.

**AXIL, AXILLA.** The angle formed between the axis and any organ that grows from it; the base of a lateral ascending organ, on the upper side.

**AXILE, AXIAL.** Of or belonging to the axis.

**AXILLARY.** Growing in the axil of anything.

**AXIS.** The stem, including the root; or any centre round which leaves and other organs are arranged. The stem is called the ascending axis, the root the descending axis. — **ACCESSORY.** An axis of a second rank; secondary to some principal axis. — **APPENDAGES OF THE.** All the leafy or thin expansions that grow upon a stem, such as leaves, and the parts of a flower.

**AYAPANA.** The sudorific *Eupatorium Ayapana*, which is said to be a valuable remedy for the bites of poisonous snakes.

**AYART.** (Fr.) *Acer opulifolium*.

**AYDENDRON.** A genus of tropical American trees of the Laurel family, *Lauro-raceæ*. They have a funnel-shaped, six-parted perianth, containing twelve stamens in four rows; the nine outer stamens have anthers, the three innermost are sterile; of the fertile stamens the three innermost have glands on each side at the base, and their anthers open outwardly; the remainder have no glands, and their anthers open

inwardly. The fruit is succulent, at first concealed within the base of the perianth, which afterwards falls off, leaving only a portion surrounding the base of the fruit.

Cujumary beans are the seeds of *A. Cujumary*, and are esteemed in Brazil as tonics and stimulants in cases of weak digestion. [M. T. M.]

**AYER AYER.** The esculent fruit of some species of *Lansium*.

**AYLMERIA.** A genus of *Paronychia*-*ceæ*, consisting of two species of Australian annuals, with much-branched stems, opposite or verticillate leaves, small scarious stipules, and terminal corymbose cymes of rose-coloured or purple flowers on long stalks. [J. T. S.]

**AZADIRACHTA.** A genus of the order *Meliaceæ*, represented by an Indian tree with unequally pinnated leaves, whose leaflets are oblique. The young shoots are smooth, not covered with down as in the allied genus *Melia*. The flowers are small, white, borne in axillary panicles; they differ from those of *Melia* in having a three-celled ovary, and a three-lobed stigma, and also in the fruit, which is purple when ripe, of the size of a small olive, one-celled, one-seeded.

The bark of *A. indica* is used in India as a tonic, the root as a vermifuge, and the leaves as an application to glandular swellings, bruises and rheumatism. They have also been employed successfully in some forms of skin disease. From the fruit an acrid oil is obtained for burning in lamps, and for dyeing cotton cloths. A stimulant gum exudes from the bark. The seeds are used as a poison for insects, and mixed with water as a hairwash. A kind of toddy is said to be prepared from the young trees. [M. T. M.]

**AZALEA.** A genus of *Ericaceæ*, established by Linnæus, and including many plants which have since been separated and arranged under different genera. So conflicting are the opinions of botanists as to the set that should retain the original Linnæan name, that it seems in danger of being lost altogether. Some seek to retain it for *A. procumbens*, as the only plant to which it is truly applicable, and propose the name *Anthodendron* for the showy shrubs so well known in our gardens as *Azalea*; whereas others, because of the almost universal application of the name to these plants, and to prevent unnecessary confusion in the synonymy, have given the name *Loiseleuria* to the small genus containing the single species, *A. procumbens*, and retained the original name for the showy American shrubs. This course being adopted generally by continental botanists, as well as by many in Britain and America, it seems better to consider the genus as so limited.

*Azalea* are upright shrubs with alternate and obovate of oblong deciduous leaves, which are entire, ciliate, and mucronate, with a glandular point. The flowers are large

and showy, often glandular, and glutinous outside; they rise in umbelled clusters from large scaly imbricated terminal buds. The calyx is five-parted, often minute. The corolla is funnel-shaped, with five spreading lobes. The stamens are five in number, with long exserted filaments, and short ovate anthers, opening by terminal pores. The ovary is five-celled, with many ovules; the style is simple. The pod is five-celled and five-valved, and contains many scale-like seeds. There are about twenty species, natives of North America and Asia. They are largely cultivated as ornamental shrubs, on account of the abundance of their flowers, and the fragrant smell of most of the species. Some possess dangerous narcotic qualities. Pallas was of opinion that *A. pontica* was the plant from whose flowers the bees of Pontus collected the honey that produced the extraordinary symptoms of poisoning, described as having attacked the Greek soldiers, in the famous retreat of the Ten Thousand. Xenophon says that after eating it, the men fell stupified in all directions, so that the camp looked like a battle-field covered with corpses. The natives are aware of the deleterious qualities of the plant. Cattle and sheep which browse on its leaves are poisoned. [W. C.]

**AZARERO.** (Fr.) *Cerasus lusitanica*.

**AZARA.** A genus of Chilian shrubs, belonging to the *Flacourtiæ* family, having twin or solitary alternate leaves, generally toothed and varying in form from egg-shaped to almost linear. Their flowers are small and yellow, destitute of petals, and arranged in axillary bundles. A few of the species are in cultivation in English gardens. *A. Gilliesii* is the most handsome. Its leaves are evergreen and somewhat like those of the holly, bearing in their axils roundish fascicles of yellow flowers. About a dozen species are known. The leaves of many have a bitter taste. [A. A. B.]

**AZAROLE.** The fruit of *Cratogeomys Azarolus*.

**AZEDARACH** *Melia Azedarach*.

**AZEROLIER.** (Fr.) *Cratogeomys Azarolus*.

**AZIMA.** *Monetia*. The plant is placed by Wight in a separate order, *Azi*.

**AZOLIA.** A very curious genus belonging to the marsileaceous division of the pseudo-ferns. Its habit is that of a floating pinnately-branched *Jungermannia*, with two or four-ranked imbricating leaves; but its fructification is totally different, and is nearer to that of *Salvinia* than of any other genus, and with which it forms a distinct section or order, according to the views of authors. Indeed, its peculiarities are such that it has been sometimes supposed to constitute a distinct order by itself. The species float upon the water, forming green or reddish patches, which are frequently several yards across, throwing down rootlets on the under side,

amongst which are situated, principally in the axils of the leaves, the organs of fructification. These are twofold:—1. Thin membranous sacs bearing on a short cylindrical axis, springing from the base, stipitate globose cysts, filled with angular bodies, which are furnished either with curious arrow-headed or root-like appendages. These armed granules are doubtless the antheridia, though their spermatozooids have not yet been discovered. 2. Ovate sporangia, divided within by a transverse partition, which incloses below, a grumous or at length pulverulent mass, and gives off from its centre above a column fringed at the apex with a tuft of hair, and having attached to it from three to nine dependent spores, which are at length exposed by the separation of the upper half of the sporangium at the above-mentioned partition. The species occur from Australia and New Zealand as far as New York. One has been found in Western Africa by Vogel. It has been supposed that the differences in the antheridia and the number of spores, accord with the geographical distribution of the species, which may accordingly be separated into two genera; but this is at present more than doubtful. [M. J. B.]

**BABEER.** A Syrian name for *Papyrus*.

**BABIANA.** A genus of bulbous-tuberous *Iridaceæ*, found in South Africa, and having two-ranked sword-shaped plicately-nerved leaves, and flower-stems terminated by a loose subsecund or two ranked spike of flowers, which consist of a funnel-shaped tube, with a dilated throat, and a six-parted regular or somewhat two-lipped limb of nearly equal segments; they are furnished with three stamens, and the three-lobed many-ovuled ovary is terminated by a filiform style, dividing at top into three conduplicate wedge-tongue-shaped undivided stigmas. The flowers are large and showy, and in some of the species sweet-scented. There are upwards of thirty species, many of which have been in cultivation in this country, and some are still occasionally met with, but, like many others, they have been undeservedly neglected in the rage for novelties which distinguishes the present age, so that they are less frequently seen than they deserve to be among the ornaments of our greenhouses. *B. plicata*, which may be taken as an illustration of the genus, is a slender plant, of six inches to a foot high, everywhere pubescent, with oblong lanceolate leaves, and pale violet-coloured flowers, the lower segments of which are streaked with yellow in the middle, and spotted with brown at the base; these flowers have the odour of cloves. [T. M.]

**BABINGTONIA.** This genus of *Myrtaceæ* was named after Professor Babington, a well-known English botanist. It is allied to the genus *Backea*, but differs from it in the stamens being collected in groups of three, opposite the petals. The anthers also are placed directly on the top of the filaments, and open by pores. The style

seems to be a direct prolongation of the placenta; it protrudes through a hole in the top of the ovary, and does not even touch the carpels. *B. camphorosma* is a graceful greenhouse shrub, with white or pinkish flowers, and has been introduced from Holland. [M. T. M.]

**BABOOL.** The Indian name for the guni-bearing *Acacia arabica*.

**BABOUNY.** A name used in Egypt for the flower heads of *Santolima fragrantissima*, a substitute for chamomiles.

**BACCA.** A berry; that is to say, a succulent seed-capsule, filled with pulp, in which the seeds nestle, as in *Solanum*. — **CORTICATA.** A berry having a rind; as an Orange. — **SICCA.** A fruit which is a berry when unripe, but becomes a dry body when ripened. — **SPURIA.** Any fleshy fruit, which is not a true bacca or berry; as the Juniper, Strawberry, Raspberry, &c.

**BACCATE.** Having a pulpy texture; a term only applied to the parts of a flower or fruit.

**BACCATE SEEDS.** Seeds with a pulpy skin.

**BACCAULARIUS.** Such a fruit as that of the Mallow; viz. several one or two-seeded dry carpels cohering round an axis.

**BACCHARIS.** A large and natural genus of the Composite family, distinguished from its allies by having male flowers only on one plant, and the females on another. Upwards of 200 species are known. They are herbs, shrubs, or sometimes small trees, many of them smooth and covered with a resinous substance, which gives to the leaves a glossy appearance. The latter are generally alternate, rarely opposite, and vary much in form. In one section of the genus they are three-nerved, and ovate or lanceolate in form; in another, one or three-nerved, and wedge-shaped; in a third they are very small, or absent altogether; while in a fourth the stems are winged and leaf-like, performing the functions of the leaves, which are small or almost absent. The flower-heads are arranged in various ways, and the florets are generally white in colour. The species are confined to the New World, and are found, in greater or less number, from the United States to the extreme south of the continent. Many of them are found at an elevation of 12,000 feet above the sea level in the Andes, and a few of them reach the snow limit. Immense tracts are covered on the plateaus of the Cordillera with plants of this genus, and shrubby groundsel, taking the same place there that the heaths do on our moors. In Peru and Bolivia, the shrubby species are known by the names of *Tola*, or *Chilca*, and by the latter name in N. Grenada and Chili. The resinous species are almost universally used as firewood for ovens. An infusion of the winged stems of *B. trimera* is used by the Brazilians as a sudorific and tonic; while another, also with

winged stoma, *B. microcephala*, is used in Parana for curing rheumatism, by putting bushes of it in warm baths. A bitter is extracted from *B. genistilloides*, which is held in great reputation in Brazil when used with a specific aroma in cases of intermittent fever. Horses devour this herb with avidity, and it is further reckoned of great service in curing chronic diseases in that animal. *B. Douglasii* is remarkable as being found in California, and appearing again in Chili, without being found in any intervening place. [A. A. H.]

**BACHE.** A South American name for *Mauritia flexuosa*, an economical species of palm.

**BACHELOR'S BUTTONS.** The double-flowered forms of *Ranunculus acris* and *Lycchnis diurna*; also *Centaurea nigra*, &c.

**BACILLARIA.** A genus of diatomaceous *Algae* consisting of a single species, which occurs on our coasts, known by its linear rectangular articulations, which are at first joined by the longer sides into a straight tabular series, and then slip over each other so as to make oblique series. The articulations or frustules, individually, are not so beautiful in respect of structure as many others of the group; the chief point of interest consisting in the curious manner in which the articulations or frustules incessantly slip backward and forward over each other, with a more or less isochronal motion, yet so as always to adhere to each other. The whole mass is thus in motion, though the several groups of frustules, of which it is composed, may be moving in opposite directions. An obstacle, says Mr. Smith, is not evaded but pushed aside; or, if sufficient to avert the onward course, the latter is detained for a time equal to that which it would have occupied in its forward progress, and then retires from the impediment as if it had accomplished its full course. The motion is about one two-hundredth of an inch per second. [M. J. B.]

**BACILLE.** (Fr.) *Crithmum maritimum*.

**BACILLI.** The separable moving narrow plates, of which the genus *Diatoma* is composed.

**BACILLUS.** The little bulbs found on the inflorescence of some plants; a term rarely employed.

**BACKHOUSIA.** Four shrubby cymose-flowered Myrtaceous plants have been associated in this genus, which is named in honour of the late James Backhouse, who travelled much in Australia and South Africa, and otherwise contributed to advance botanical science. The principal characters of the genus are: the tube of the calyx covered with dense hairs, the five segments of the limb large, whitish, and petal-like; the petals themselves small and comparatively inconspicuous; the stamens very numerous, and longer than the calyx or the corolla; the ovary

adherent below to the tube of the calyx, but free at its upper portion, very hairy on the exterior, the interior containing several seeds in each of its two compartments. *B. myrtifolia* is a small tree, with opposite ovate pointed leaves, and stalked corymbs of whitish flowers, and is cultivated as a greenhouse plant. [M. T. M.]

**BACTRIDIIUM.** A very curious genus of *Fungi*, of rather doubtful affinity, but supposed to belong to the division coniomycetes, and to be allied to *Coryneum*. The plant consists almost entirely of oblong septate hyaline spores, which radiate from a little dot-like receptacle. The spores in our most conspicuous native species, *B. farum*, which occurs in this country, although but rarely, on dead elm stumps, are of a pale yellow. We have a species from Venezuela, with enormous spores, one-sixteenth of an inch long, which afford an interesting microscopic object under a low magnifying power; in this the spores, when seen en masse, are of a pale fawn colour. [M. J. B.]

**BACTRIS.** A genus of slender Palms, natives of the West Indies, Brazil, and other tropical countries on the eastern side of South America; generally growing in low marshy places, or inundated tracts of land, upon the banks of rivers, and on the sea coast. There are about forty species, but very few of them attain anything like the majestic proportions of the generality of palms, the majority having thin reed-like stems, not much exceeding the height of a man. A few, however, grow to a height of forty or even fifty feet, with trunks averaging about four inches in diameter. Almost all of them are armed with sharp black or brown spines, several having their stems encircled with bands of them, placed at short intervals all the way up, whilst others have them only at their summits; and, as they usually grow together in large masses, and throw up numerous suckers from their creeping roots, they offer a really formidable and often impassable barrier both to man and beast. Their flower-spikes are produced either from the apex of the trunk or from the bases of the leaves, and while young are enclosed in a double sheathing spathe, which, in nearly all the species, is densely covered with short black spines. The male and female flowers are borne upon the same spike, and are yellow, green, or rose-coloured; the males have a three-parted thin calyx; and three fleshy petals, and contain from six to twelve stamens; the females have a cup-shaped or cylindrical calyx and corolla, three-toothed at the apex, and they contain a triangular ovary, with three sessile stigmas. Their fruits are generally small, seldom exceeding a pigeon's egg in size, and frequently not larger than a pea, mostly of a bluish black colour, having a thin coating of white fibrous pulp surrounding a hard black stone, which has three small holes at the top, and contains a single seed. Their leaves do not fall away from the trunk like those of many other palms, but remain

attached long after they have withered, hanging down and concealing the trunk; they are nearly always pinnate, and from two to eight feet long; in a few species, however, the leaves are nearly entire, or merely divided into two broad sharp-pointed lobes.

**B. Maraja**, the Marajah Palm of Brazil, grows upon the banks of the Amazon and other rivers. It is the largest species of the genus, its trunk attaining a height of fifty feet. It is thickly armed with spines, and has a succulent rather acid but agreeably tasted fruit, from which a vinous beverage is prepared. **B. minor** has a stem about twelve or fifteen feet high, and seldom more than an inch in diameter. It is common in Jamaica and some parts of tropical South America, growing in open places in the vicinity of woods. Its stems are used for walking-sticks, and are said to be sometimes imported into this country under the name of Tobago canes. [A. S.]

**BADAMIF.** An Indian name for Oil of Almonds.

**BADDERLOCKS.** *Alaria esculenta*.

**BA'DEK.** A fermented liquor prepared in Java from rice.

**BADGER'S-BANE.** *Aconitum melocotnum*.

**BADHAMIA.** A genus of gelatinous Puffballs (*Myzogastrea*), named after the late Dr Badham, remarkable for its spores being contained in little groups in distinct hyaline sacs or asci, whereas in most of the immediately allied fungi they are naked. The species were formerly referred to *Physarum*. Other instances of asci occur in the same division, as in the genus *Enerthenema*, separated from *Stemonitis*. The most common species, perhaps, is *B. hyalina*, which is known by its delicate peridia as well as by its long confluent yellowish stems. [M. J. B.]

**BADIANE.** (Fr.) *Illicium*.

**BADIERA.** A genus of the Milkwort family (*Polygalaceae*), which includes three species, all of them natives of the West Indian Islands. They are woody plants with evergreen leaves, and axillary corymbs of white or greenish-yellow flowers, differing chiefly from the common Milkworts (*Polygala*), in having a large oily aril to the seed which fills the upper part of the cell, and in the anthers opening inwards by an oval partitioned slit. The bark of *B. diversifolia* is acrid and bitter, like that of the Lignum Vitæ, and is called Bastard Lignum Vitæ, in Jamaica, on this account. [A. A. B.]

**BADIOUS.** Chestnut-brown.

**BADULA.** A genus of the *Myrsine* family, of which seventeen species are enumerated. They are evergreen shrubs or small trees, with smooth entire dotted leaves, having short and broad foot-stalks. Their flowers are numerous, disposed in axillary or terminal panicles, and either white, dotted or streaked with pink, or entirely of a pink

colour. The fruits are small scarlet or black berries, containing few seeds. They are nearly related to *Ardisia*, and differ chiefly from that genus in their short round-headed stigma, and few seeds. Their distribution is unusual, one being found in the Philippine Isles, a considerable number in Mauritius, Bourbon, and Madagascar, but the greatest number in the West Indies, Peru, and Brazil. [A. A. B.]

**BÆA.** A small genus of *Gesneraceae*, consisting of herbaceous plants, with short stems or stemless, and having crowded leaves. The calyx is five-partite and persistent; the corolla is campanulate, the tube scarcely as long as the calyx, while the sublabiate limb is five-parted with roundish lobes. There are two fertile stamens with very short filaments, and large cordate-ovate anthers. The lanceolate ovary is one-celled, with two parietal placentæ. The capsule is elongated and pod-shaped, and the two valves, after dehiscence, are spirally twisted to the right. The oblong seeds are numerous and very small. This genus differs from *Streptocarpus* chiefly in the length of the corolla tube. [W. C.]

**BÆCKEA.** The name of a genus of plants belonging to the *Myrtaceæ*. The flowers are sessile or stalked; the limb of the calyx five-cleft, persistent, its tube top-shaped; petals five, longer than the stamens, which are from five to ten in number, and distinct; stigma capitate, capsule many-seeded. The plants are small shrubs, with opposite leaves, and white flowers. They are natives of New Holland and China. Some of them are in cultivation as pretty greenhouse plants. [M. T. M.]

**BÆOMETRA.** Certain bulbous plants, belonging to the order *Melanthaceæ*, are so called. From the bulbs or corms arise narrow sheathing leaves and spikes of flowers, each of which latter has a six-parted petal-like spreading deciduous perianth, into the base of the segments of which the six stamens are inserted. The ovary is somewhat triangular, and terminated by three recurved spreading stigmas; it ripens into a cylindrical capsule, its three compartments separating one from the other at the top, so as to liberate the numerous seeds, which are of a compressed four-cornered shape, arranged in two lines along the inner edge of each compartment. They are all natives of South Africa. [M. T. M.]

**BÆOMYCES.** A small genus of Lichens, distinguished amongst *Lecidinei* by their subglobose terminal fruit, which is supported by a short unbranched stem. The disc is generally bright-coloured, as rose, chestnut, &c. *B. roseus* and *B. ericetorum*, which abound in heaths, are often taken at first-sight for fungi. [M. J. B.]

**BAERIA.** A genus of Composites, allied to *Callichroa*, of which but a single species is known, the *B. chrysotoma*, from California. It is a pretty dwarf annual, of

slender erect habit, with downy stems about a foot high; linear opposite entire leaves and solitary terminal bright yellow flowers, an inch across. Botanically, the genus is distinguished by an involucre of about ten leaflets, arranged in two series, a conical naked receptacle, and an elongated fruit without pappus. It differs from *Callicroa*, not only in its general habit, but also by its smaller flower-heads, and the oblong-pointed form of the ray florets, the florets of the latter being wedge-shaped. [W. T.]

**BAGASSA.** An imperfectly-known genus of *Artocarpaceae*, comprising one or more species of trees, with opposite leaves, deciduous stipules, and orange-shaped fruit, consisting of egg-shaped, pointed achenes, clustered around a thick central receptacle. This fruit is eaten in Guiana, where the tree is a native. [M. T. M.]

**BAGUENAUDIER.** (Fr.) *Colutea arborescens*. — **DETHIOPIE.** *Sutherlandia frutescens*.

**BAJREE.** *Penicillaria spicata*, a bread-corn cultivated in India.

**BALANITES.** The name given to a thorny shrub or small tree, with a very forbidding aspect, growing almost always in dry barren places. Its leaves grow in pairs (binate), the leaflets oval, or oblong, stalked, and pubescent when young. The flowers are small, greenish, white and fragrant, arranged in short axillary racemes. The fruit is oval, about one and a half inch long, and when ripe of a greyish colour. The plant is a native of many parts of India, Egypt, Senegambia, and the W. coast of Africa. The leaves in the Egyptian variety are slightly acrid and anthelmintic, and the bark is used by the Ryots in India as a medicine for their cattle. The young fruits are purgative, but when ripe are edible, and formed into an intoxicating drink by the negroes on the W. coast of Africa. In India the nut, which is very hard, is employed in fireworks. A small hole being drilled in it, and the kernel taken out, it is filled with powder and fired, bursting with a loud report. An oil, called by the negroes *Zachun*, is obtained from the seeds, and the wood, which is yellow, hard, and durable, is used in Africa for household work. The place of the plant in a natural arrangement has been considered as somewhat doubtful, but recent authorities place it in the *Simarubaceae*. [A. A. B.]

**BALANOPHORACEÆ.** (*Cynomorpha*.) A small natural order, consisting of about thirty species, of singular-looking succulent leafless plants, usually highly coloured, of various shades of yellow or red; all parasites on roots, and rising from an inch or two to about a foot above ground. Their colour and consistence, the absence of all leaves, excepting in some species, imbricated scales of the colour of the rest of the plant, and the greatly reduced structure of induced some botanists to

consider them as cryptogams allied to fungi; but their structure is now much better understood, and has been fully described, especially by Dr. J. D. Hooker. He has shown them to be most nearly connected with *Haloragaceae*, and to have no real affinity with *Rafflesiaceae*, *Orobanchaceae*, or any other root parasites, which assume sometimes a similar colour and consistence. The flowers are, in nearly all the species, unisexual, of very simple structure, and produced, in considerable numbers, in compact terminal heads or cones; the small perianth, usually simple and inferior in the females, more or less three-cleft or six-cleft in the males, is in some species wholly wanting; the stamens, usually few, are very variable in number and form; the ovary has one or two styles, and always a single cavity with one pendulous ovule.

The *Balanophoraceae* are natives of hot climates, in various parts of both the New and the Old World, one species only, the *Cynomorium coccineum* or *Fungus meliense* of old authors, being found as far north as the southern shores of the Mediterranean. They have been distributed into fourteen genera. The most remarkable for the size or beauty of the species, or for the use made of them, are *Sarcophyte*, *Lophophytum*, *Ombrophytum*, *Langsdorfia*, and *Cynomorium*.

**BALANOPHORA.** Singular leafless parasitical plants, giving their name to the order *Balanophoraceae*. These plants are found on the roots of oaks, maples, vines, and other trees in tropical countries, especially in mountainous districts. One species is found in Australia. Some of the Himalayan species cause the formation of large knots on the roots of oaks and maples, which are much sought after by the natives for the manufacture of wooden cups, in general use in the Himalaya and Tibet. Some of the species, as *B. elongata*, furnish wax in great abundance, which is used for making candles in Java. [M. T. M.]

**BALANSEÆ.** A genus of *Umbelliferae* or *Apiaceae*, consisting of one species, inhabiting North Africa. It has a tuberous root, large broadly cut leaves, and hermaphrodite flowers. Each half of the fruit is compressed laterally, elongated into a conical 'stylod', terminated by an erect style, and marked by five prominent thread-like ridges, in the intervals between which, in the round, run solitary channels, or 'vittæ', filled with volatile oil, while in the commissure are two such channels; albumen furrowed. [M. T. M.]

**BALANTIUM.** A name proposed for a genus of Ferns, now considered synonymous with *Dicksonia*. It is represented by the *Dicksonia Culeitis* of Madeira. [T. M.]

**BALATA.** A kind of caoutchouc yielded by *Sapota Molleri*.

**BALAUSTA.** The pomegranate fruit.

**BALAUSTION.** A Greek word for the pomegranate, but applied by Sir W. Hooker to another genus of *Nyctagaceae*. *B*

*pulcherrimum*, the only known species, is described as being one of the most lovely of plants. It is a shrub, with a thick twisted stem, numerous slender branches crowded together in places, and short linear leaves, dotted with resinous fragrant cysts. The flowers are abundant, placed towards the end of the branches, in shape and colour like those of the dwarf pomegranate, but drooping on short stalks, with two small coloured bracts beneath the calyx, which has a cup-shaped tube, adherent by the base only to the ovary; the remainder is detached, and the limb divided into five ovate membranous spreading segments; the petals are five, oval, slightly larger than the calyx, and of a deep scarlet or crimson colour. The stamens are very numerous inserted in one row at the throat of the calyx; anthers inserted on the awl-shaped filaments by their backs, the lobes parallel, splitting by a long cleft. Ovary small, top-shaped, with three compartments, each containing about six ovules, placed one over the other in a double line; style thread-shaped; stigma rather dilated. A native of South-western Australia. [M. T. M.]

BALD-MONEY, or BAWD-MONEY, *Mecum athamanticum*.

BALFOURIA. A genus of the natural family *Apocynaceae*, consisting of shrubs with opposite narrow sickle-shaped leaves. The flowers are arranged in cymes at the end of the branches, or from their side, and have a five-parted calyx, a funnel-shaped corolla, with its limb divided into five straight equilateral lobes, having also at its throat a small coronet or tube with a wavy margin. The five stamens are inserted on the throat of the corolla, from which they protrude. The anthers are arrow-shaped, provided with a sharp point or mucro, and adherent to the angular stigma; style thread-shaped; ovaries with two compartments. They are natives of tropical Australia, and have not yet been introduced into cultivation. [M. T. M.]

BALISIER. (Fr.) *Canna indica*.

BALLOTA. A family of herbaceous plants belonging to the Labiate order, among which they are distinguished by the strongly ten-ribbed salver-shaped calyx. They are natives of the temperate regions of the Eastern hemisphere, and are remarkable for nothing but their strong offensive odour, on account of which they are for the most part rejected by cattle; hence the name from the Greek *ballo*, to reject. *B. nigra*, Black Stinking Horsehound, a common wayside perennial, has stout-branched stems, egg-shaped wrinkled leaves, and whorls of numerous dull purple flowers. The whole plant is as offensive in odour as it is unattractive in appearance, and suffers little from being generally covered with dust. It is mostly found growing near towns and villages, and has accompanied our colonists to many remote countries. In Gotland, according to Don, it is a universal remedy

in disorders incident to cattle. French *Ballote*; German, *Zahnlose*. [C. A. J.]

BALLOTE. (Fr.) *Ballota nigra*.

BALM. *Melissa officinalis*. —, BASTARD. The common name for *Melittis*. —, FIELD. *Calamintha Nepeta*. —, HORSE. An American name for *Collinsia*. —, MOLDAVIAN. *Dracocephalum moldavicum*. —, MOLUCCA. The common name for *Moluccella*. — of GILEAD. A resinous product of *Balsamodendron gileadense*, and *B. Opobalsamum*, called sometimes Balm of Mecca; also, a garden name for *Dracocephalum canariense*; also, an American name for *Populus candicans*. — of GILEAD (AMERICAN). A resin obtained from *Teica carana*. — of MECCA. The same as Balm of Gilead, a resinous product of *Balsamodendron*.

BALOGHIA. The name given to a tree of the Spurgewort family (*Euphorbiaceae*), which attains the height of twenty to thirty feet, and has opposite entire oblong leaves, which are stalked, and have at their base two membranaceous stipules which fall early. The flowers are numerous, and are disposed in terminal cymes, the males having a calyx of five divisions, five petals longer than the calyx, and a large number of stamens, their stalks united at the base, while the calyx and corolla of the female flowers are as in the male, and their ovary is three-celled, each cell containing one ovule. *B. lucida* is the only species known, and it is found in Norfolk Island, where it is called Blood Wood, as also in the colony of Queensland, in N. Holland. The wood is close-grained, impregnated with a resinous substance, and burns readily in a green state. A blood-red sap oozes from the trunk when cut, and is obtained in the following manner in Norfolk Island: 'A knife, similar to a farrier's, is used, but stronger, fixed upon a handle four to five feet long, which enables the workman to reach high up the trunk of the tree. A perpendicular incision is made through the bark, an inch wide at the surface, but tapering to a point near the wood, and from eight to ten feet long, forming the main channel through which the sap flows to the base of the tree, where a vessel is placed for its reception; branch channels are cut on each side of the main one, leading obliquely into it, six or eight inches apart, and extending nearly two-thirds round the trunk. The sap generally flows from these channels for about twelve hours, when it is collected. The quantity produced by each tree varies: sometimes about a pint, but on an average about a gill.' The sap forms an indelible paint, and was formerly used in the island for marking bags, blankets, and other articles. [A. A. B.]

BALSAM. A name given to various gum-resinous or oleo-resinous vegetable substances. —, BAYEE. A product of *Balsamodendron pubescens*. —, CANADIAN. A product of *Abies balsamea*. —, CARPATHIAN. A product of *Pinus Cembra*. —, COPALM. A product of *Liquidambar styraciflua*. —, GARDEN. *Impatiens Bal-*

*samina*, sometimes called *Balsamina hortensis*. —, HUNGARIAN. An oleo-resinous product of *Pinus Pumilio*. — of ACOUCHI. A product of *Icica Aracouchini*. — of CAPIVA. An acrid product of various species of *Cupaterra*. — of MARIA. A product of *Verticillaria acuminata*. — of PERU. A product of *Myrospermum peruvianum*. — QUINQUINO. A product of *Myrospermum pubescens*, sold as White Balsam. — of TOLU. A product of *Myrospermum toluiferum*. — of UMIRI. A product of *Humirum floribundum*. —, TAMACOARI. A product of a Brazilian species of *Caraipa*. —, WHITE. The Balsam of Quinquino.

**BALSAM BOG.** *Bolax glebaria*.

**BALSAM HERB.** A garden name for *Justicia comata*.

**BALSAM SEED.** A garden name for *Myrospermum*.

**BALSAM TREE.** A common name for *Cissia*, and *Balsamodendron*.

**BALSAM WOOD.** An American name for *Gnaphalium polycephalum*, a plant used in the manufacture of paper.

**BALSAM WOOD.** A garden name for *Myroxylon*.

**BALSAMINACEÆ.** (*Hydroceræ*). The large genus *Impatiens*, and a single species separated from it under the name of *Hydrocera*, included by Jussieu in the *Geranium* family, have been raised to the rank of a distinct order, on account of the remarkable irregularities in the flowers, which have been variously explained by different botanists. The sepals and petals, all coloured, consist usually of six pieces, two outer ones, small, flat and oblique, the next large, hood-shaped, ending below in a conical spur; the fourth opposite to it, small, but yet very broad and concave, the two innermost very oblique, and more or less divided into two unequal lobes. It has been a matter of much dispute which of them should be considered as sepals and which as petals. It has now, however, been proved by the examination of some Asiatic species, where there are two additional small sepals, and especially of the *Hydrocera*, where the flowers are less irregular, that the two outer pieces, and the large spurred one, with the two occasional additional ones, are the sepals, that the two innermost lobed pieces consist each of two united petals, and that the broad concave one is the fifth petal, thus bringing the structure more in conformity with that of true *Geraniaceæ*, with which Balsams agree also in their ovary, and in the fruit which, in bursting open, leaves the attachment of the seeds adhering to the persistent axis. The *Balsaminaceæ* may therefore be again considered as a tribe only of *Geraniaceæ*.

**BALSAMINA.** A name sometimes given to the garden Balsam, and some few species resembling it in habit, but which are, how-

ever, more usually and correctly referred to *Impatiens*. [T. M.]

**BALSAMINE.** (Fr.) *Impatiens Balsamina*.

**BALSAMITA.** A genus belonging to the natural order *Compositæ*, belonging to that group in which the florets are all hermaphrodite, and distinguished by having a naked receptacle, no pappus, and an imbricated involucre, &c. One species of this genus, grown for culinary purposes, the common Costmary or Alecost (*Balsamita vulgaris*), is a native of Italy, from whence it was introduced in 1568. It is a creeping-rooted hardy perennial, from two to three feet high, remarkable for the strong balsamic odour of its leaves, which are roundish, oblong, and toothed, and were formerly put into ale and negus; hence its old English name of Alecost; whilst that of Costmary is from the old Latin name *costus amarus*, or the French *coste amère*. Although common in every cottage garden, it is almost entirely discarded from the plants that are grown for culinary purposes; and even in France it is only used occasionally to mix in salads. The plant is the *Pyrethrum Tunacum* of Linnaeus. [W. E. B.]

**BALSAMOCARPON** belongs to the Pea family (*Leguminosæ*), and is a native of the province of Coquimbo, in Chili, where it is common in dry hilly places. There is but one species, *B. brevifolium*, the Algarrobo of the Chilians. It is a shrub with undivided elongated branches, having many tubercles; from these the leaves proceed, and are accompanied with two or three short spines. The leaves are simply pinnate, and are not more than half an inch long, the leaflets six in number and very small. The flowers are large, yellow, and arranged in few-flowered clusters at the ends of the branches, their calyces covered with long glandular hairs. The pods are thick, short and sessile, and are remarkable for being almost entirely transformed into a cracked resinous substance, which is astringent, and used commercially for dyeing black and making ink. [A. A. B.]

**BALSAMODENDRON.** A word, as the name implies, applied to certain balsam-bearing trees, of the natural order *Amyridaceæ*. Their foliage is generally scanty, pinnated, and the branches frequently spiny. The flowers are small, green, axillary, often unisexual, with a four-toothed persistent calyx, four narrow petals bent inwards, and eight stamens, inserted with the petals beneath a circular cup-shaped disc, from which arise eight small lobes, which alternate with the stamens. The fruits are small, oval and drupe-like, with four sutures. The nut is thick and hard, two-celled or sometimes one-celled by abortion; each cell contains one seed.

*B. Myrrha*, a plant growing wild in Arabia Felix, is supposed to yield some of the gum resin known as Myrrh. *B. glaucodes* and *B. Opobalsamum* are stated to

produce Balm of Gilead, or Balm of Mecca, sometimes called Opobalsamum, a gum resin obtained by incision into the bark, and considered by the ancients as a panacea for almost all the ills that flesh is heir to. *B. Kataf*, one of the plants supposed to yield Myrrh, has a red resinous wood, which is a common article of sale in Egypt. *B. africanum*, a species found in Abyssinia and Western Africa, yields a resin known as African Bdellium, and the Indian drug of the same name is the produce of another species of this genus, *B. Roxburghii*, or of the closely allied one *Amyris*. Bdellium is like myrrh in its properties, but is not considered so good; it is moiater than myrrh, not brittle, and has not so agreeable an odour. It is rarely used in this country.

*B. Mukul* yields a resin known in Scinde under the name of Googul, and in Persia as Mukul. The late Dr. Stocks has shown that this is identical with the Bdellium of Dioscorides and of the Scriptures. The tree producing it is abundant in Scinde, in rocky ground, and the resin is collected by making incisions into the tree and letting the resin fall on the ground, hence it is mixed with much dirt and many impurities. The resin has cordial and stimulant properties. It is given as a medicine to horses in Cabul; it is also used as a plaster for boils. It is burnt as incense, and is mixed by builders with the mortar used in the construction of houses, when durability is an object. A similar resin with the same native name is obtained in other parts of India, from other species of the genus.

Balsamodendron Mukul.

*B. pubescens*, according to Dr. Stocks, furnishes Bayee Balsam, which is brittle, but tasteless and inodorous. The bark of this tree peels off in thin layers like that of the Birch. As is so frequently the case, there is considerable doubt as to the plants producing these several gum-resins, though it is agreed on all hands that the plants, whatever their species may be, belong to this genus; nay, it is not unlikely that more than one species may furnish the same kind of resin. *B. sesianicum* is cultivated in this country as an ornamental stove plant. [M. T. M.]

**BALSAMORRHEIZA.** A genus of the Composite family (*Compositæ*). Seven species are enumerated, all of them dwarf

perennial herbs, with fleshy radical leaves, which are heart-shaped with long stalks, or pinnatifid. Their stems are simple, usually bearing a solitary flower-head, which is about two inches in diameter, having the appearance of a small sunflower. All the florets are yellow in colour, and the greater part of the species are covered with a whitish pubescence. They are found on the west side of the Rocky Mountains, in Oregon and California. The thick roots of *B. Hookeri*, which is found on gravelly banks of the Columbia river, yield a copious pellucid resin, which has a powerful turpentine-like odour, while those of *B. meana* and *helianthemoides* are eaten by the Indians in Oregon. They are cooked on hot stones, and have a sweet and rather agreeable taste. The name is given from the occurrence of a balsamic resin in the roots of some of the species. [A. A. B.]

**BAMBOO.** The common name of *Bambusa*. Bamboo-caness are the stems of different kinds of *Bambusa*. —, SACRED, of the Chinese: *Nandina domestica*.

**BAMBUS.** A genus of Grasses, typical of the tribe *Bambusaceæ*. This tribe is remarkable among those belonging to the great family of Grasses, in consequence of the gigantic size some of its species attain. The flowers are hexandrous, more rarely triandrous, and are produced in panicle spikelets. Occasionally some are neuter, and others male only. Steudel describes thirty-three species, which are all natives of warm countries, and have an extensive range over the surface of the globe. It is *B. arundinacea*, which is generally considered to be the species the largest and best canes are produced from, but frequent errors regarding it no doubt occur, and the canes of other species are mistaken for it. *B. vulgaris*, with *culmi inermes*, appears to be the species which is generally cultivated in British gardens, whereas the *B. arundinacea* is described with *culmus spinosus*. In the East and West Indies the canes frequently grow from fifty to sixty feet high; and even in this country they have been known to grow forty feet in one season, in some of the large Palm-houses. The finest known species is, perhaps, *B. latifolia*, a native of the Orinoko, which produces much thicker and larger canes in every way than those of *B. vulgaris* or *B. arundinacea*. A fine plant of the large sort is growing in the Botanic Garden at Berlin.

The variety of purposes to which the Bamboo is applied is almost endless. The Chinese use it, in one way or other, for nearly every thing they require. The sails of their ships, as well as their mats and rigging, consist chiefly of Bamboo, manufactured in different ways. Almost every article of furniture in their houses, including mats, screens, chairs, tables, bedsteads, and bedding, are made of the same material. (See *Library of Entertaining Knowledge*.) A similar extensive use of the hollow reed is made in Japan, and also in

VEGETATION OF RAMBOOS IN JAVA (After Blume)

Java, Sumatra, and other eastern countries. Although the Bamboo grows spontaneously and most profusely in nearly all the immense districts included in the southern portion of the Chinese empire, the people do not rely on the beneficence of nature, but cultivate the gigantic reed with much care. They have treatises and whole volumes solely on this subject, laying down rules derived from experience, and showing the proper soils, the best kinds of water, and the seasons for planting and transplanting the useful production. (*Ibid*) A view of the Bamboo vegetation of Java is given in Plate 4. See Gen. Munro's valuable *Monograph of Bambusa*, in *Trans. Linn. Soc.* (xxvi. 1). [D.M.]

BANANA. *Musa sapientum*.

BANANIER. (Fr.) *Musa*.

BANNETTE. (Fr.) *Dolichos melanophthalmus*.

BANARA (including *Asca*, *Bosca*, *Kuhlia*, and *Pineda*). A genus of *Samydaceae*, confined to the tropical parts of America, and consisting of about fifteen species, all of which are either small trees or shrubs, with ovate leaves, and paniculate, racemose or fasciculate flowers. The calyx is four to five cleft; the petals from four to five in number; the stamens disposed in several rows, inserted in a perigynous disk, and indefinite. Uses unknown. [B.S.]

BANDAKAL. The fruits of *Abelmoschus esculentus*.

BANDED. Marked with cross-bars of colour.

BAND-SHAPED. Narrow and very long.

BANDALA. The strong outer fibre of *Musa textilis*, from which Manila white rope is made.

BANDOLIER FRUIT. The berries of *Sanonia indica*.

BANEBERRY. *Actaea spicata*.

BANG. A narcotic preparation from the leaves of the Hemp, *Cannabis sativa*.

BANGIA. A genus of *Algae*, which deserves notice as connecting the filamentous with the membranous series, the perfect plant of *B. atropurpurea*, closely resembling very young examples of the common *Porphyra*, which produces the laver of our oil shops. Like *Porphyra* its place is doubtful, as it has almost equal claims to be ranked amongst the green and rose-aped genera. Both, however, are usually placed amongst *Chlorosperma*. *B. atropurpurea* is a common species on old jetty piles, &c., and is a pretty microscopic object. We do not consider such species as *B. setifina* belonging to the same section. See ULVA and PRASIOLEA. [M. J. B.]

BANISTERIA. A name applied to a genus of the natural family *Malpighiaceae*, consisting of trees or shrubs, frequently climbing, with simple stalked leaves, often provided with glands on the stalks. The

have a five-parted with glands at its base external petals are furnished with long stalked claws; there are ten stamens, frequently somewhat coherent at the base; three styles, often leaf-like at their extremities; and three carpels, each containing one seed, and terminating in a simple membranous wing. The seed-leaves or cotyledons are thick and unequal. The plants are natives of Brazil and the West Indies; several are in cultivation for the sake of their pretty yellow flowers, and, in some instances, fine foliage. [M. T. M.]

BANKSIA. A genus of *Proteaceae*, established by the younger Linnaeus, and named in honour of Sir Joseph Banks. It is distinguished by having four-parted apetalous flowers, the anthers of which, four in number, are subsessile and attached one to the concave apex of each sepal; the style is filiform or subulate, with a clavate or cylindrical stigma. The seed-vessel, which is termed a follicle, is large and woody, and contains large winged seeds which are generally black. The genus is peculiar to Australia and Tasmania. In the former colony it is very generally distributed throughout the extratropical portion, while only two intertropical species have been discovered, viz.:—*B. compar* at Keppel Bay, on the east coast, and *B. dentata* at Arnheim's Land, on the north coast, and at Endeavour River, on the north-east coast. There are upwards of fifty species known, of which only a few become trees. Mr. C. Frazer mentions having seen a specimen of *B. grandis* which he considered to be fifty feet in height, and with a stem two and a half feet in diameter. The other arborescent species are *B. littoralis*, *B. cylindrostachya*, *B. australis*, *B. prionotes*, *B. Menziesii* and *B. ilicifolia*. The remainder are more generally shrubs of from fifteen to twenty feet in height, though in some instances, as *B. nutans*, *B. pulchella* and *B. spharocarpa*, of much humbler growth. The foliage is remarkable for its harsh rigid coriaceous character, and the leaves are generally dark green on the upper surface, and clothed with a white or rufous down beneath, their margins being either deeply serrated or only spinous, rarely entire. Their form is singularly variable, thus in *B. Meisneri* they are small, reflexed and sharp pointed; in *B. spinulosa* and *B. ericifolia* they are linear, three to four inches in length, and about an eighth of an inch in breadth. *B. latifolia* is distinguished by having lanceolate leaves, nearly a foot long and three inches broad, covered with a rich rufous down on the underside. *B. Solandri* has broad ovate leaves, deeply sinuated. *B. speciosa* and *B. Victoriae* have long linear leaves (fourteen inches) covered with whitish down beneath. *B. dryandroides* and *B. Brownii* have very elegant foliage, the latter bearing very much the appearance of a species of *Mimosa*. *B. coccinea* is remarkable for its large head of deep red flowers. One species, *B. integrifolia*, is named the Honeysuckle by the

australian colonists, in consequence of the great quantity of honey which the flowers contain. These plants, from their handsome and peculiar foliage, have always been great favourites in gardens. The appearance of the *Bankesia* in their native habitats is shown in a view of the vegetation of New South Wales, taken near Port Jackson, which forms the subject of Plate 5. [It. H.]

**BANQUOIS.** A name given in the Mauritius to a species of Screw-pine, *Pandanus vauca*, the leaves of which are used for making sacks.

**BANYAN-TREE.** *Ficus indica*.

**BAOBAB-TREE.** *Adansonia digitata*.

**BAPHIA.** A genus of Leguminous plants (*Fabaceae: Papilionaceae*), ten species of which are described, all of them Tropical African; one species, *B. racemosa*, extending to Natal. They are either trees or shrubs, and have unifoliate leaves. Their flowers are produced in clusters, upon short stalks at the bases of the leaves, each flower having two small bracts underneath its calyx; they have a sheathing calyx which splits along the underside, and is either entire or five-toothed; their corolla is papilionaceous; and they have ten free stamens, all fertile. The fruit is a narrow flattened pod, of a leathery texture, and having its edges slightly thickened; it contains numerous seeds, and splits open when ripe.

*B. nitida*, which produces the Camwood or Barwood of commerce, is an erect shrub, eight or ten feet in height. It has ovate or oblong shining green leaves, four to six inches long, composed of two pairs of leaflets, with an odd one, and its yellow flowers bear some resemblance to those of the common laburnum of our gardens. About 300 or 400 tons of the wood of this tree are annually imported from Sierra Leone, being collected from various parts of the coast between that place and Angola. In 1838 the imports were 464 tons, valued at 13,833*l*. It usually comes in trimmed logs, about four feet in length and a foot in diameter, but sometimes, though rarely, in the form of balls or cakes, made of the roughly powdered wood. It is of a deep red colour, and yields a brilliant but not permanent dye; with a mordant of sulphate of iron it produces the red colour of the English Bandana handkerchiefs, and dyers generally employ it for much the same purposes as the better known Brazil-wood. The native women on the West coast of Africa use the pounded wood for painting their bodies; amulets are also made of it, and it is used in their Fetish ceremonies. [A. S.]

**BAPTISIA.** American herbaceous plants belonging to the order *Leguminosae*, among which they are distinguished by their two-tipped calyx, by their petals, which are equal in length, their deciduous stamens, and swollen pod, which is supported by a stalk, and many-seeded. All the species are her-

baceous, and, with one exception, *B. p. foliata* (in which the leaves are simple and entire), have trifoliate leaves. They grow from one to two feet high, and bear blue or yellow flowers, either solitary or in clusters. They are ornamental border flowers, and being perennial may be increased by division of the roots. One species, *B. tricoloria*, a native of dry hilly woods from Canada to Carolina, has been used as indigo by dyers, and from this the name (from the Greek *bapto*, to dye) was given to the genus. The root and leaves are said to possess astringent and antiseptic properties. The species most frequently cultivated are *B. australis* (French, *Baptise de la Caroline* or *Podalyre*), a pretty border plant, with large blue flowers, tinged on the keel with greenish white, and arranged in a long cluster; and *B. minor*, a smaller plant with blue or white flowers. [C. A. J.]

**BARANETZ, or BAROMETZ.** *Cibotium Barometz*, called the Scythian Lamb. *Barun* is Russian for Lamb.

**BARBA JOVIS.** *Anthyllis Barba Jovis*.

**BARBACENIA.** A genus of monocotyledonous plants, related to *Vellonia*, and referred with some doubt to the order *Hamodioraceae*. It consists of perennial herbs, with simple or dichotomously-branched stems, which sometimes attain two or three feet, or sometimes more, in height, and are furnished at the ends with spirally disposed firm spreading narrow acutely-keeled leaves, from amongst which issue one-flowered scapes, which are usually clothed with glandular and resiniferous hairs, especially towards the top. The flowers are large and generally showy, and consist of a funnel-shaped perianth, resinously-hairy on the outside, the base of the tube confluent with the ovary, and the limb spreading, of six equal segments; there are six included stamens, having plano-compressed filaments, which are three-toothed at the apex, the middle tooth being the smaller and bearing the anther. The ovary is three-celled, containing numerous ovules affixed in the central angles of the cells, and becomes a cylindraceo-three-cornered capsule. The style is triquetrous, three-parted, and the stigma is capitate, three-cornered. There are upwards of a dozen species, all South American, and nearly all found in Brazil, where they occur in hot dry mountain regions, lying between 14° and 20° S. lat. *B. Alexandrinae*, found in the southern parts of British Guiana by Sir R. Schomburgk, is stated to grow from ten to twelve feet high. *B. purpurea*, one of the most familiar species, is frequently met with in hothouses, and affords a very good illustration of the family. This has a short dichotomous striated stem, bearing numerous linear acuminate rigid leaves, sheathing at the base, and minutely spiny-toothed at the margin. The flower-stalks are longer than the leaves, one-flowered; the flowers erect, rich violaceous purple, with lanceolate segments, the three inner of which are broader and more erect than the

outer three, which are narrower and spreading. It is a plant of ornamental character. *B. squamata* is similar in habit, but is dwarfer, with a more scaly stem, and smaller reddish flowers. Between these species some very showy hybrids have been raised in gardens. [T. M.]

**BARBADOS PRIDE.** *Poinciana pulcherrima*.

**BARBAREA.** Winter-cress. A herb held in some repute in the days when the field or brook furnished the only salads, but banished from the table by vegetables of better flavour. The common species, *B. vulgaris*, is a weed frequent in gardens and waste grounds, where the soil is damp. In winter and early spring it is a tuft of pinnate glossy leaves, of a dark green hue, sending up in May an erect leafy stalk, having numerous yellow flowers, which are succeeded by largish four-angled pods. *B. praecox*, Early Winter-cress, is a smaller plant of similar habit; it is well-distinguished by the slender divisions of its upper leaves, and its very narrow pods. This, which is sometimes called Land-cress, to distinguish it from Water-cress, to which its leaves bear some resemblance, though common enough in the West of England, is considered a relic of cultivation. A variety of the common species is sometimes cultivated for the sake of its double flowers, under the name of Yellow Rocket Herb (French, *Julienne jaune*). The French name of the wild plant is *Barbarrée* or *Herbe de St. Barbe*: German, *Winterkresse*. [C. A. J.]

**BARBATE.** Having long weak hairs in one or more tufts.

**BARBE-DE-BOUC.** (Fr.) *Spiraea Aruncus*. — **DE CAPUCIN.** *Nigella damascena*. — **DE-CHEVRE.** *Eryngium campestre*, also *Spiraea Aruncus*. — **DE JUPITER.** *Anthyllis Barba Jovis*, also *Centranthus ruber*.

**BARBEAU.** (Fr.) *Centaurea Cyanus*. — **JAUNE.** *Centaurea Amberboi*. — **MUSQUE.** *Cent ureau moschata*. — **VIVACE.** *Centaurea montana*.

**BARBELLÆ.** The hairs of the pappus of Composites, when they are short, stiff, and straight.

**BARBELLULÆ.** Small conical spine-like processes of the pappus of Composites, as in *Aster*.

**BARBERRY.** The Berberry, *Berberis vulgaris*.

**BARBON.** (Fr.) *Andropogon*.

**BARBS.** Hooked hairs.

**BARBULA.** The inner row of fringes or teeth in the peristome of such Mosses as *Forcula*. Also the name of a genus.

**BARBYLUS.** A genus now united with *Fraxillita*, a member of the natural family *Melissaceae*. Its describer speaks of the single species, *B. sumatrensis*, as a tree in-

habiting Jamaica, with a rough bark, alternate pinnate leaves, and the flowers in racemes. The calyx is bell-shaped, four to five-cleft; the corolla, with four or five petals, arising from the margin of the calyx; stamens eight to ten, arising from the bottom of the calyx; ovary free; style and stigma simple; capsule with three two-seeded compartments. [M. T. M.]

**BARCLAYA.** A singular genus of *Nymphaeaceae*, not much resembling ordinary water-lilies in appearance, though botanically allied to them. It consists of aquatic plants with tuber-like root-stocks, whence the leaves and flowers spring. The calyx is composed of five distinct sepals; the corolla is tubular at the base, and united below to a disc surrounding the ovary, the limb being divided into five red-coloured petals; stamens numerous, in several rows, inserted on the tube of the corolla, the upper ones sterile; the anthers are without appendages. Fruit adhering to the fleshy disc, composed of several carpels, with radiating stigmata. Each compartment of the fruit contains several seeds, which are albuminous internally, and externally covered with thick bristles. These curious plants are natives of the East Indies, and are especially remarkable for the calyx consisting of distinct sepals detached from the ovary, while the petals are united together below, and are attached to a disc in which the ovary is immersed, so as to give an appearance as though it were inferior, which, however, is not the case. [M. T. M.]

**BARDANA.** The Burdock, *Arcium Lappa*, or *Lappa major*.

**BARDANE.** (Fr.) *Arcium Lappa*, or *Lappa major*.

**BARDANETTE** or **B. FAUSSE.** (Fr.) *Echinopspermum Lappula*.

**BARK.** All the outer integuments of a plant beyond the wood, and formed of tissue parallel with it. The only true bark is that of *Exogens*. In *Endogens*, False Bark, also called Cortical Integument, stands in place of bark, from which it is known by the fibrous tissue of the wood passing into it obliquely.

**BARK.** The official name given to the cortical layers of various plants, used chiefly for medicinal and tanning purposes. The name is, *par excellence*, applied to the Peruvian or Cinchona bark, the source of quinine. Of these there are many varieties, namely:—*Calisaya*, Royal Yellow, *Cinchona Calisaya*; Light *Calisaya*, *C. scrobiculata* β. *Delondriana*; Carabaya, Ash, Jaen, *C. ovata*; Dark Jaen, *C. villosa*; Hard Carthagena, *C. cordifolia*; Woody Carthagena, *C. Condaminæ*; Spongy Carthagena, Coquette, Bogota, *C. lanceolata* = *Condaminæ* β.; Crown, *C. Calisaya*; Select Crown, *C. chahuanguera*; Ashy Crown, *C. macrocalyx*, *rotundifolia*; Fine Crown, *C. crispata*; Loza Crown, *C. Condaminæ*; Wiry Crown, *C. Mirinda*; Cinnamon, *C. coccinea*;

Cusco, Arica, *C. pubescens*; Red Cusco, St. Ann's, *C. scrobiculata*; Huanuco, Grey, *C. micrantha*, *glandulifera*, *nitida*; Original Loja, *C. urubitinga*; Negrilla, *C. heterophylla*; Red, *C. conglomerata*; Genuine Red, *C. succubra*; Spurious Red, *C. magnifolia*. The principal sorts are sometimes classed thus:—GREY BARKS: Crown or Loja, *C. Condaminea*, *scrobiculata*, *macrocalyx*; Lima, Huanuco, Silver, *C. micrantha*, *lanceolata*, *glandulifera*, and probably *purpurea*. RED BARKS: *C. nitida*. YELLOW BARKS: *C. Calsaya*, *micrantha*, *Condaminea*, *lanceifolia*. RUSTY BARKS: *C. hirsuta*, *micrantha*, *ovalifolia*, and probably *purpurea*. WHITE BARKS: *C. ovata*, *pubescens*, *cordifolia*. For a complete account of the medicinal cinchona barks, see Mr. Howard's splendid volume, entitled *The Nueva Quinologia of Pavon*.

The following Barks are also employed officially or economically:—ALCORNOCO or ALCORNOQUE. The astringent bark of several species of *Byrsionia*; or, according to some authorities, of *Bowditchia virgiloides*.—ANGOSTURA. The febrifugal bark of *Galipea cusparia* or *G. officinalis*.—BABUL. The astringent bark of *Acacia arabica*.—BASTARD CABBAGE. The bark of *Andira inermis*: same as Worm Bark. —BASTARD JESUITS. The bark of *Iva frutescens*.—BONACE. The bark of *Daphne tinifolia*.—CANELLA. The stimulant aromatic bark of *Cunella alba*.—CARIBBEAN. The astringent bark of *Ezootemma caribbeum*.—CASCARILLA or SWEET WOOD. The aromatic bark of *Croton Cascarilla* and *C. pseudo-china*.—CHINA. The febrifugal bark of *Buena hexandra*.—CONESSI. The astringent bark of *Wrightia antidysenterica*.—CULILAWAN. The aromatic stimulant bark of *Cinnamomum Culilawan*.—ELEUTHERA. The aromatic bark of *Croton Cascarilla*.—FALSE ANGOSTURA. The bark of *Strychnos nuxvomica*.—FRENCH GUIANA. The febrifugal bark of *Portulandia hexandra*.—JESUITS. The same as Peruvian Bark. —JURIBALI. An astringent bark of Demerara, supposed to be the produce of some *Cedrelaceous* plant. —MELAMBO. The aromatic febrifugal bark of some species of *Galipea*, or one of its allies. —MEZEUREUM. The acrid irritant bark of *Daphne Mezereum*.—MONESIA. The bark of some S. American *Sapotaceae*.—MURUXI. The astringent bark of *Byrsionia spicata*, used by the Brazilian tanner. —NIEPA. The febrifugal bark of *Samadera indica*.—PANOCOCCO. The sudorific bark of *Swartzia tomentosa*.—QUERCITRON. The yellow dye bark of *Quercus tinctoria*.—QUILLAI. The bark of *Quillata saponaria*, used as a substitute for soap. —STRINGY, of Tasmania. *Eucalyptus gigantea*.—SWEET WOOD. The same as Cascarilla Bark. —NINE. An American name for *Spiraea opulifolia*.—WHITE WOOD. The same as Canela Bark. —WINTER'S. The tonic aromatic bark of *Drymis Winteri*.—WORM. The bark of *Andira inermis*, formerly used as an anthelmintic.

**BARKERIA.** A small genus of beautiful Orchids, from Mexico and Central America, differing in little from *Epidendrum* except in the column being bordered by a broad membranous wing. About half-a-dozen species are known, of which *B. spectabilis*, called in Guatemala Flor de Isabel, is the finest. It is one of the votive offerings of the Catholics in that country.

**BARKLYA** *syngisfolia*, the only species of a genus belonging to the section of the Pea family bearing regular flowers, is a large tree, with alternate simple coriaceous leaves, which have long stalks, and are in form like those of the Iliac (*Syringa*), but have seven radiating nerves. The flowers are golden yellow, very numerous, and disposed in axillary or terminal racemes. The pods are stalked, about half an inch long, thin, and containing few seeds. The tree has been lately introduced into English gardens. It is a native of Eastern Australia, and is found near the Brisbane river. The genus bears the name of Sir Henry Barkly, formerly governor of the colony of Victoria. [A. A. B.]

**BARLERIA.** A large genus of herbs or shrubs, natives of the tropical regions of both the Old and New Worlds, and belonging to that division of the *Acanthaceae* in which the corolla lobes are imbricate or twolipped in the bud, and not contorted, and the seeds are inserted on hooked retinacula. The flowers of this genus are axillary, or in terminal spikes or heads, and have herbaceous or pungent bracts. The calyx has four sepals, the two outer being larger than the others; the corolla has a long tube, and five nearly equal spreading lobes. Of the four stamens the upper pair are sometimes abortive; the anthers are linear and parallel. The two-celled ovary has two ovules in each cell; the style is entire with a truncate stigma. The capsular fruit is acuminate. The allied genera all have a distinctly two-lipped corolla, and are thus easily distinguished. [W. C.]

**BARLEY.** The common name for *Hordeum*, a genus of corn-producing Grasses. Pearl Barley is the grain of the common Barley deprived of its hard integuments.

**BARNADESIA.** A genus of the Composite family, belonging to that section of the order which has two-lipped corollas. All the species are spiny bushes, furnished with entire generally elliptical or lanceolate pointed leaves, each having at its base two spiny stipules. The flower-heads are terminal and elongated. The florets and often the involucre are purple or pale pink in colour. The pappus is feathery, and the achenes are clothed with silky hairs. *B. rosea* has delicately flesh-coloured florets, which are covered with silky hairs, and is a favourite plant in the tropical houses of English gardens, being a very free bloomer. The species, nine in number, are natives of tropical S. America. The genus is named in honour of Michael Barnades, a Spanish botanist. [A. A. B.]

**BARNARDIA.** A genus of *Littaceæ*, containing rather small bulbous plants, resembling *Scilla*, natives of China and Japan. They have linear cuspidate radical leaves, and scapes bearing small pink flowers in racemes; filaments winged and ciliated at the base; ovary three-celled, each cell with one ovule erect from the base—which distinguishes it from its allies. *B. scilloides* is a pretty frame plant. [J. T. S.]

**BAROMETZ.** *Cibotium Barometz*.

**BAROSMA.** This name has been applied to a genus of *Rutaceæ*, on account of the heavy powerful odour that the species possess. The genus is botanically characterised by an equally five-parted calyx; five oblong petals; ten stamens, of which five are sterile and petal-like, alternating with the five shorter fertile stamens; the style of the same length as the petals; and the ovary five-lobed. The species are small evergreen shrubs, with opposite or alternate simple dotted leathery leaves, in the axils of which the flowers are placed on stalks. They are all natives of the Cape of Good Hope, where the leaves, which have a rue-like smell, are used by the Hottentots to perfume themselves with!

*Barosma crenulata.*

They also use a tincture of the leaves as an application to wounds, and in urinary diseases. Several species are used by the Hottentots under one common name of Bucku. The Bucku leaves of commerce are produced chiefly from *B. crenulata*, *B. crenata*, and *B. serratifolia*. Bucku leaves are much used in medicine as a stimulant and tonic, and appear to have a specific effect in chronic diseases of the bladder, their action probably being dependent on the powerfully-smelling volatile oil which they contain. [M. T. M.]

**BARRALINGUE.** (Fr.) A kind of Olive.

**BARRAS.** The French name of the resinous exudation of *Pinus maritima*, the bark of Burgundy Pitch.

**BARRENWORT.** The common name for *Epidemium*.

**BARRINGTONIACEÆ.** (*Barringtoniads*.) A small family consisting of about five-and-twenty species, usually considered as forming a tribe of *Myrtaceæ*, with which they agree in the structure of their ovary and perianth, and in the very numerous perigenous stamens, turned inwards in the bud. They differ chiefly in the presence of albumen in the seed. Their leaves are also alternate, not dotted, and often serrated, but these characters occur also occasionally in true *Myrtaceæ*. They are all trees or shrubs, inhabiting the tropics in the New and the Old World, some of them bearing large flowers of considerable beauty. The principal genera are *Barringtonia* and *Careya* in the Old World, and *Gustavia* in the New.

**BARRINGTONIA.** This typical genus consists of trees, sometimes of large dimensions, with alternate opposite or whorled leaves, often of large size and generally obovate in form, their margins toothed or entire. The flowers are in spikes or racemes, generally large and handsome, and in colour pink, scarlet, or white. The stamens are very numerous and form a conspicuous feature in the flower, from the great abundance of yellow anthers; the filaments, being slightly united at the base, fall off in the form of a ring when the flower fades, and have the appearance of a painter's brush. Their fruits are one-seeded, fleshy, more or less four angled, and in the larger-flowered species about two inches in length, tapering towards the base. They are found in many parts of India, but in the greatest numbers in the Malayan peninsula and the Islands of the Indian Ocean; two species are present in N. Australia, and one grows on the banks of the Zambesi River in East Africa. Without exception they are beautiful objects when in flower.

The bark of a number of the species has narcotic qualities. *B. acutangula*, an Indian species, grows to a large size, and bears some resemblance to an oak in its branching. It yields a solid durable wood, useful for ordinary purposes; and from the leaves an extract or juice is obtained which, when mixed with oil, is used in native practice for eruptions of the skin. The kernels, powdered and prepared with sago and butter, are used in diarrhoea; mixed with milk they promote vomiting. Young plants of this species are shown in Plate 10, figure 4. *B. speciosa*, a native of the Moluccas, and one of the handsomest of the genus, attains the height of forty or fifty feet, with a circumference of ten to fourteen feet; it is generally found near the sea. From its seeds a lamp-oil is expressed; mixed with bait they are used to inebriate fish, in order to facilitate their capture.

The root of *B. racemosa* has a bitter taste, and is used by Hindoo practitioners on account of its aperient and cooling qualities. The seeds and bark are also used in native medicine, the latter is of a reddish colour, and is said to possess properties akin to those of quinine (*Cinchona*). The pulverised fruit is used as snuff, and, com-

bined with other remedies, is applied externally in diseases of the skin. The genus

*Barringtonia speciosa*

was dedicated to the Hon. Daines Barrington, the English antiquary. [A. A. B.]

**BARROWIA.** A genus of *Asclepiadaceae*, containing a single species, from the Cape of Good Hope. It is a slender branched and climbing plant, with oblong-lanceolate leaves, and three or more white flowers on interpetiolar peduncles. The calyx is five-parted, with lanceolate erect sepals. The funnel-shaped corolla is slightly swollen at the base, and the limb is cleft into five lanceolate spreading divisions. The gynostegium is included, and has the sinuous staminal corona attached to its base. The ovoid pollen masses are attached to a small corpuscle by slender processes, and have a projecting pellucid apex. The stigma is five-lobed, with a slightly projecting central cone. [W. C.]

**BARTERIA.** Two tropical African shrubs, with alternate glabrous entire or crenate leaves, and rather large sessile axillary flowers, forming a genus of *Passifloraceae*, allied to *Smacthmannia*, but differing chiefly in the stigmas being consolidated into one large terminal capitate mass, exceeding the ovary in diameter, and in the fruit, which is said to be an indehiscent berry the size of a pigeon's egg.

**BARTHOLINA.** This is one of a singular race of terrestrial Orchids, peculiar to the Cape Colony, with solitary shaggy leaves, small white flowers, and a great lip cut into narrow strips, resembling the teeth of a comb. They have been grown in this country, but perish after having been imported for a year.

**BARTLINGIA.** This genus was founded upon some specimens collected by Sieber in New South Wales, in very young bud only. They had been referred to *Rhynchos* by Sieber, who named them *Cryptandra obovata*. Brongniart subsequently referred them to *Boronia* (near *Amphidulia* and *Chrysothuliza*), under the name of Bartlingia. Reichenbach

referred the plant to *Myrtaceae*, in which he was confirmed by Schauer. Benthams, however, has discovered that it is the leguminous *Pultenaea obovata*, in a young and uncharacteristic state. [J. Br.]

**BARTONIA.** A showy group of annual North American Loasads, of which the *B. aurea*, a Californian species, is one of the best known. The most important features of the group are, a cylindrical or club-shaped calyx tube, with a five-parted persistent limb; five or ten flat spreading equal petals; numerous stamens; and a capsule having the seeds arranged in two rows on each of the parietal placentae, opening at the summit when ripe. The *B. aurea* is a succulent branched spreading plant, of a greyish-green aspect, growing two feet high, with lanceolate plumatid roughish foliage, and large lustrous golden yellow blossoms in terminal clusters, expanding only in the middle of the day. When in perfection, it is really a splendid plant, and may be made to contribute greatly to the gaiety of the borders; for, although its habit and foliage are less attractive than those of some other annuals, in size and brilliancy of blossoms it is inferior to none. There are several other species peculiar to the Western and North Western States, of which the most remarkable is the *B. ornata*, with very large white flowers, figured many years since in the *Botanical Magazine*, under the name of *B. decapetala*, from dried specimens, but apparently unknown in England in the living state. By some botanists the *Bartonia*s are not considered distinct from *Mentzelia*. See also *Centaurella*. [W. T.]

**BARTRAMIA.** A genus of Mosses, included in the order *Bryocera*.

**BARTSIA.** Unpretending annuals, belonging to *Scrophulariads*, and distinguished from *Rhinanthus* (Yellow Rattle) by having the upper lip of the corolla arched, and not laterally compressed. *B. Odontites* is a common weed by waysides and in corn-fields, growing from six to eight inches high, with an erect branched stem, bearing many one-sided clusters of inconspicuous dull purple flowers; the foliage is scanty, and the whole plant roughish, and tinged more or less with purple. A less common species is *B. viscosa*, which grows in marshes and damp pastures to the height of six to twelve inches, and bears numerous bright green leaves, which are narrow, cut at the edges, and taper to a point: it is very common in many parts of Devon and Cornwall, where it sometimes grows two feet high. The flowers are solitary, imbedded among the leaves, and much larger than in the last. The whole plant is singularly clammy to the touch. *B. alpina* is a rare species, found only in rocky mountainous pastures in the north. All the species turn black in drying. [C. A. J.]

**BARU.** A woolly material, found at the base of the leaves of *Saguera saccharifer*, sometimes called *Arenga saccharifera*.

**BARWOOD.** An African dye wood, produced by *Baphia nitida*.

**BARYA.** A genus of begoniads, established by Klotzsch, and consisting of herbaceous plants, found on the mountains of Peru. The staminate flowers have four, and the pistillate five sepals; anthers elliptical and short; filaments united; style persistent, with elongated branches, surrounded by an interrupted papillose band, making five spiral turns; placentas stalked, with two lamellae. There is one known species, namely, *B. monadelphica*, gathered by Ruiz, under the name of *Begonia monadelphia*, near Muña, in Peru. The genus is named after Dr. Ant. de Bary, a patron of botany. [J. H. B.]

**BASAL.** Growing at the base of anything, as ovules at the base of an axile placenta.

**BASELLACEÆ. (Basellads.)** A small family, chiefly distinguished from *Chenopodiaceæ* by what has been called a double calyx, and perigynous stamens; but the so-called outer calyx consists merely of the two bracts, which are here adnate to the perianth, instead of being free, or at some distance from it; and more or less perigynous stamens occur also in other chenopodiaceous genera. *Basellaceæ* have therefore been now re-united with that family as a tribe. They are mostly herbaceous climbers, with more or less succulent leaves, and small inconspicuous flowers. The perianth is usually thick and fleshy, and the style is three-cleft, whilst in true *Chenopodiaceæ* it is more frequently (but not always) only two-cleft. There are sixteen or seventeen species, all tropical, and they have been distributed into six genera, of which the most important are *Basella*, *Boussingaultia*, and *Auredera*.

**BASELLA.** A genus of climbing plants, belonging to the order or tribe *Basellaceæ*. The simple ovary becomes converted into a membranous fruit, which is adherent to the inner part of the persistent calyx, and contains a single seed, with little or no albumen, and an embryo, coiled up spirally, like a watch-spring. *B. alba* and *B. cordifolia* are cultivated in the East Indies as pot herbs, and are used as a substitute for spinach. *B. rubra*, a variety of *B. cordifolia*, yields a rich purple dye, but it is difficult to fix. These plants are grown in India over trellis-work, where the succulent shoots and leaves form an agreeable protection from the sun. Some of the species have tuberous roots. *B. alba* is in cultivation, and might with advantage be more frequently grown from a suspended basket, as its appearance when in bloom is elegant. [M. T. M.]

**BASIBRACTEOLATE.** A term applied chiefly to the involucre of a composite, when it is surrounded at the base by a distinct order of bracts, as in dandelion.

**BASIDIA.** Little elevations found among fungi, consisting of a single

cell, having one or more points at its apex, each bearing a spore; synonymous with Sporophores.

**BASIDIOSPORES.** The spores which stand upon the basidia.

**BASIFIXUS.** Attached by the base.

**BASIL, BUSH.** *Ocimum minimum*, a dwarf pot-herb. — **SWEET.** *Ocimum Basilicum*, an aromatic pot-herb. — **WILD.** *Calamintha Clinopodium*.

**BASILAR.** Seated at the base of anything.

**BASILIC COMMUN. (Fr.)** *Ocimum Basilicum*. — **DE LA CHINE.** *Plectranthus nudiflorus*. — **PETITE.** *Ocimum minimum*. — **ROMAIN.** *Ocimum Basilicum*.

**BASIL-THYME.** *Calamintha Achnos*.

**BASINERVED.** When the ribs of a leaf all spring from its base, as in most Melastomads.

**BASISOLUTE.** A term applied to leaves which, like those of *Sedum* and *Echeveria*, are extended downwards below their true origin.

**BASSIA.** A genus of the natural order *Sapotaceæ*, consisting of tropical trees, with alternate entire leaves, and whitish axillary stalked flowers, having a calyx of four or five sepals, a fleshy corolla, tubular below, but divided at its limb with eight segments. Stamens numerous; ovary terminated by a tapering style, and containing six to eight compartments, of which three or four undergo an arrest of growth, so that the pulpy fruit does not contain more than three or four one-seeded cells.

*B. butyracea*, the Indian Butter tree, or Phulwara, is a native of Nepal, and the Almorah hills. From its seeds when bruised and pressed is squeezed out a fatty substance of the consistence of hog's lard and of a white colour. It is used to adulterate ghee, and is considered serviceable in rheumatism, and as an application to the hair. It makes good soap, and is adapted for burning. It is soluble in warm alcohol, and does not become rancid when kept, but is completely melted at a temperature of 130°. From the juice of the flowers a kind of sugar is prepared.

*B. latifolia*, the Mahwah tree of Bengal, furnishes a hard and strong timber used for the wheels of carriages, &c. The flowers are sweet-tasted and are eaten raw, and they are also largely made use of in the distillation of an ardent spirit like whisky, which is consumed in great quantities by the natives of Guzerat, &c. When frosh it is very deleterious to Europeans. The seeds yield an oil used for lamps, in the manufacture of soap, and for culinary purposes; but it is thick, coarse, and only used by the poorer classes. The Bheels are stated to collect the sweetly tasting flowers of this plant, and dry them to store as a staple article of food; and hence, 'in expeditions undertaken for the punishment or subjection of these tribes when unruly, their

*Bassia* trees are threatened to be cut down by the invading force, and the threat most commonly ensures the submission of the tribes.—(*Gibson*.)

The flowers of *B. longifolia* are roasted and eaten in Malabar and Coromandel; they are also bruised and boiled to a jelly. The leaves as well as the milky juice of the unripe fruit are used medicinally. The bark contains a gummy juice which exudes and is used in rheumatism; the bark itself is likewise employed as an astringent, and as a remedy for the cure of the itch. The seeds furnish an oil like that of the other kinds, but of an inferior quality.

The Shea tree or Butter tree of Africa, whose seeds produce the Galani butter, mentioned by Mungo Park in his travels, is a species of this genus, *B. Parkii*, or of the closely allied one, *Lucuma*. The seeds are boiled in water to extract the butter from them. This fatty substance is of a white colour, and agreeable taste, and keeps well, hence it is an important article of commerce in Sierra Leone. Some of the species of this interesting genus are in cultivation. [M. T. M.]

BASSIN D'OR. (Fr.) *Ranunculus repens*.

BASSINET. (Fr.) *Ranunculus repens*.

BASSORA GUM. A partially soluble gum of uncertain origin, supposed to be the produce of a *Cactus* or *Mesembryanthemum*.

BASS-WOOD. The American Lime or Linden, *Tilia americana*.

BAST A strong woody fibre, much used for brooms, brushes, &c., obtained from the leaf-stalks of *Aitaea funifera*, and of *Leopoldinia Pissaba*. Also, the inner bark of the Lime tree, of which the Russian mats used in gardens are made. — CUBA. The fibrous inner bark of *Peritium elatum*, much used for tying up cigars, and in gardens for tying plants, as also is the bast of the Lime tree.

BATARREA. A genus of *Fungi* allied to the Puffballs. Its most striking characteristics are a thick gelatinous volva, a tall rigid stem, and a hemispherical cap-shaped peridium. Some of the filaments, moreover, have a spiral structure, a very rare circumstance amongst *Fungi*. The British species is extremely rare, and occurs on sandhills, for the most part near the sea, or amongst the vegetable soil in hollow trees. The habit is that of *Phallus*, and the volva with its intermediate gelatinous coat is precisely the same. The early stage of this plant has not been observed since the true structure of the hymenium in the higher fungi has been ascertained; but there can be little doubt that it resembles that of the true puffballs. [M. J. B.]

BATATE. (Fr.) *Batatas edulis*, formerly *Convolvulus Batatas*.

BATATAS. A genus of Bindweeds (*Convolvulaceae*), of which about twenty species are described, mostly natives of tropical

America. They are creeping or twining, herbaceous or shrubby plants. Their flowers have a bell-shaped corolla, enclosing the stamens, and a four-celled ovary, with a single style and a two-lobed capitate stigma.

The most interesting species is *B. edulis*, the tuberous roots of which, under the name of Sweet Potato, are extensively used in many warm countries in the same way that we use common potatoes. The plant has a creeping or sometimes twining stem five or six feet long, and either running along the ground, or rambling over other shrubs. Its leaves are about six inches long and heart-shaped at the base; and its flowers resemble those of the common *Convolvulus*, of a pale purple colour, and arranged in threes or fours on a stalk. This plant has been so long cultivated and naturalised in various tropical countries, that its precise origin is somewhat obscure, but probably it is indigenous to both hemispheres. The first mention of it is said to be by an author named Pigafetta, who went to Brazil in 1510, and found it in use among the Indians as an article of food. It was soon afterwards introduced into Spain, where it is still cultivated. The roots were known in England before the introduction of the common potato, with which they were frequently confounded by early writers. They were imported in considerable quantities from Spain and the Canary Islands, and, when steeped in wine, or made into sweetmeats, were supposed to have the effect of restoring decaying vigour. At the present day Sweet Potatoes are largely cultivated in many tropical and sub-tropical countries; such for instance as India, China, Japan, the Malayan Archipelago, &c., in the east; and in the west, very generally throughout tropical America, also in Texas, Alabama, Carolina, and other Southern States of America, extending even as far north as New York, where, however, they are not found to be a profitable crop: they are also grown to a small extent in the south of

*Batatas edulis*.

Europe, and more extensively in the Canary Islands, Madeira, and North Africa. There are several varieties, some having

white roots and others red. The roots grow to a very great size; according to Crawford they sometimes attain the enormous weight of fifty pounds in Java; but in the United States the general weight is from three to twelve pounds each tuber, and the yield per acre is estimated at from 200 to 300 bushels. They have an agreeable sweetish taste, and contain rather more flesh-forming matters than the common potato, considerably more sugar, and a slight excess of starch.

*B. Jalapa* has large tuberous roots and creeping stems like the last. The leaves of this species are heart-shaped, of a deep green upon the upper surface, and covered with a white woolly down beneath; and the flowers are either white or rose-coloured, and very showy. It is a native of Mexico, growing commonly in the vicinity of the town of Jalapa, whence the specific name *Jalapa* is derived. It was formerly supposed to produce the Jalap of the Pharmacopœia, but that drug is now known to be derived from another plant of the same natural order; the roots of *B. Jalapa*, however, possess purgative properties, and are probably sometimes substituted for true jalap.

*B. paniculata* has thick smooth twining stems and large hand-shaped leaves; and its flowers are very handsome and of a fine purple colour. It is a native of India, Java, New Holland, Mauritius, West Africa, Guiana, Brazil, &c.; and is the species commonly cultivated for food in Western tropical Africa. From the seeds of a species of this genus is obtained what is called Natal Cotton, a textile material resembling true Cotton. [A. S.]

**BATEMANNIA** *Colleyi* is an inconspicuous Orchid with dull brownish-purple flowers, from Demerara. It differs in little from *Mazillaria*, excepting having an anther-bed with a membranous border. Some other plants bearing this name belong to the genus *Galeotia*.

**BATEMIUM**. A name given by Link to a group of large-growing Ferns now included in *Aspidium* and *Sagenia*. [T.M.]

**BATIDÆÆ**. The *Batis maritima*, a low shrubby succulent plant, with opposite leaves, abundant in the salt-marshes on the sea-coasts of the West Indies, has much puzzled botanists as to its real affinities. They have therefore, in compliance with a custom now very prevalent in similar cases, endeavoured to solve the

The females have a two-lobed sessile stigma, without either perianth or stamens. The seed has no albumen, and the embryo is but little curved; yet Grisebach is probably right in proposing once more to include it among the *Chenopodiaceæ*, with which it accords in outward appearance.

**BATIS**. This genus of *Exogens* has a structure so anomalous that it has been separated as a distinct order, *Batidææ*. The leading features have been just explained; in addition to which it may be remembered that the naked ovaries adhere to each other in the form of a short green four-ribbed cone. Each ovary consists of two carpels, the stigmas being only two; but it is four-celled, with one ovule in each cell, in consequence of the dorsal rib of each carpel being inflexed so as to form a partition, the partition passing between the two ovules, making the two-celled ovary four-celled, with one ovule in each cell. The ovule is erect from the base of the cell. The seed contains no albumen, and the embryo has an inferior radicle. The position of the *Batidææ* in the natural system is a question of much interest with botanists, who have assigned it widely different stations. There is no doubt, however, that it has some relation with the *Callitricheæ*, and in common with that order shows some resemblance to the *Caryophyllaceæ*. The writer has also suggested a very near affinity with the *Verbenaceæ*, which have the same kind of four-celled ovary. (*Trans. Linn. Soc.* xxii. 411). The plant is sometimes used in making West Indian pickles, and its ashes yield large quantities of barilla. [B. C.]

**BATODENDRON**. A name applied to a genus of *Vacciniaceæ*, more commonly considered as a section of the genus *Vaccinium*. It is known by its flowers being borne on long thread-like stalks, in leafy or leafless clusters; the corolla five-lobed, spreading, bell-shaped; filaments hairy; anthers provided with two long awns bent backwards; fruit berry-like, almost tasteless, its cells few-seeded by abortion. The species are all natives of America and Mexico. [M. T.M.]

**BÂTON BLANC** or **ROYAL**. (Fr.) *Asphodelus ramosus*. — DE JACOP. *Asphodelus luteus*. — DE SAINT JEAN. *Polygonum orientale*.

**BATRACHOSPERMEÆ, BATRACHOS-**

the small green flowers half buried in a succulent spike, give it a great general resemblance to *Salticornia*; but the ovary having (according to Torrey) four cells with one erect ovule in each, differs materially from that of *Chenopodiaceæ*. The flowers are in unisexual cylindrical spikes. The males, solitary, under imbricated bracts, have a two-lobed calyx and four stamens, alternating with as many minute scale-like petals, or rather staminodia,

in distinct groups, in one of which the frond is cartilaginous, solid or hollow, with the outer coat cellular; in the other it is made up of a central articulated axis coated with close-packed descending threads, covered with whorls of necklace-like brachlets at regular intervals. In both, the fruit consists of chains of spores, which are external in the latter, internal in one genus, at least, of the former. *Batrachospermum* belongs to the second group. Its species

which are highly gelatinous, vary from black to nearly violet, but are never of a deep rose as in the analogous rose-spored *Alga*. *B. montiformis* is a common inhabitant of our rivulets, where it is found attached to stones or roots, and never fails to obtain admiration when closely examined. Most of the species grow in fresh water. The genera of the first group will be noticed under *Lemanea*. [M. J. B.]

**BATSCHIA.** A genus of *Menispermaceæ*, allied to *Abuta* and *Anelasma*, but differing from both in its three to five-nerved leaves, which are almost glabrous. The genus is imperfectly known. Mr. Benthams is of opinion that it should be merged with *Abuta*. The plants included in it are natives of Darien. The name has been applied to certain Boraginaceous plants now included under *Lathospermum*, and also to a group of *Leguminosæ*, now referred to *Humboldtia*. [M. T. M.]

**BAUDRIER DE NEPTUNE, (Fr.)** *Laminaria saccharina*.

**BAUBERACEÆ.** The genus *Bauera*, belonging to the *Hydrangeæ* family (or tribe of *Rubiaceæ*), has by some botanists been thought to possess distinctive characters sufficient to establish it as a separate family under the name of *Baueraceæ*, which has not, however, been generally adopted.

**BAUERA.** A genus of *Hydrangeaceæ*, consisting of small shrubs found in Australia. They have opposite sessile trifoliate leaves, with oblong undivided leaflets, and no stipules; and the flowers are handsome nodding, rose-coloured or purple, axillary, solitary on rather long stalks, rarely terminal and clustered; calyx with six to ten segments, adhering to the base of ovary; corolla of six to ten petals; stamens numerous; styles two. [J. T. S.]

**BAUHINIA.** This genus of *Leguminosæ* plants (*Fabaceæ*: *Cæsalpiniæ*) was selected by Plumier to bear the name of two brothers, John and Caspar Bauhin (celebrated botanists of the sixteenth century), in consequence of most of the species having their leaves composed of two lobes, which are either quite separate, or, more frequently, joined together by a portion of their inner margins, and which Plumier thought symbolic of the united labours of the two Bauhins in the cause of science. The numerous species are extensively diffused throughout the tropics, particularly in Brazil and India. They are generally climbers, frequently attaining a gigantic size; some few, however, form trees or large shrubs. Their flowers are produced either singly or in racemes opposite the leaves, and have a calyx with a cylindrical tube split on one side, or rarely five-parted; five unequal spreading petals, inserted along with the stamens into the top of the calyx-tube; ten stamens, which are either joined together at the base or distinct, a portion of them being sometimes barren; and a long-

stalked ovary, which ultimately becomes a many-seeded two-valved pod.

*B. tomentosa* is a native of Ceylon, where it forms a small tree, growing about fifteen feet high, and having pale yellow flowers spotted with crimson, which has given rise to the superstitious idea that they are sprinkled with the blood of St. Thomas, hence the tree is called St. Thomas' tree. Its leaves are composed of two oval, blunt-topped leaflets joined together for more than half their length, and hairy on the under side. The dried buds or flowers, and also the leaves, are employed by the native Indian doctors as a remedy against dysentery.

*B. Yahnii* is the Maloo climber of India, a plant whose gigantic shrubby stems often attain a length of 300 feet, and climb over the tops of the highest trees of the forest, twisting so tightly round their stems that they not unfrequently strangle and cause death, the stems ultimately decaying and leaving a sheath of climbers standing in their place. The young shoots and leaves are covered with a rust-coloured scurf, and are furnished with tendrils. The leaves are very large, often more than a foot in diameter, composed of two oval-shaped lobes joined together for about half their length, and heart-shaped at the base. The flowers are snowy-white, and arranged in racemes. The exceedingly tough fibrous bark of this species is employed in India for making ropes, which, from their great strength, are used in the construction of the suspension bridges across the river Jumna. The bark of another Indian species is used for making the slow-matches used with native guns.

*B. variegata* is a small tree of about twenty feet in height, a native of India, China, and the Molucca Islands, and now naturalised in some of the West India Islands. It has two broadly egg-shaped leaflets joined for about one-third their length; and its rosy-white flowers are produced in twos upon a forked stalk. The wood of this species is of a dark colour, and forms one of the many woods called Ebony; the bark is used medicinally in India, and also for dyeing and tanning leather. [A. S.]

**BAUME A' COCHON, or A' SUCRIER.** (Fr.) A balsaminous resin produced by *Hedwigia balsamifera*. — A' SALADE. *Mentha viridis*. — COQ or GRAND. *Balsamita vulgaris*, or *Pyrethrum Tanacetum*. — DE CANADA. *Abies balsamea*. — DE PÉROU. *Myrspermum peruviferum*. — DE PÉROU FAUX. *Melilotus carui.* — DE VANILLE. A liquid which exudes from the Vanilla. — DES JARDINS. *Mentha rubra*. — D'ORMEAU. A balsaminous product contained in galls borne by the Elm, *Ulmus campestris*, in Italy, France, Persia, &c. — SAUVAGE. *Mentha rotundifolia*.

**BAUMIER.** (Fr.) *Populus balsamifera*. — DE GILÉAD. *Abies balsamea*.

**BAWCHEE SEED.** An all seed, the produce of *Psoralea corylifolia*.

**BAWDMONEY, or BALDMONEY.** *Meum Athamanticum*.

**BAXTERA.** A little known genus of *Asclepiadaceæ* from Brazil, containing a single species, an erect shrub with opposite cordate-elliptical leaves, and reddish flowers in terminal umbels. The calyx is five-parted. The tube of the corolla is dilated below, and the limb is five-cleft. The staminal corona consists of five fleshy leaves. The anthers are terminated by a membranaceous appendage. [W. C.]

**BAY, INDIAN or ROYAL.** *Laurus indica*. —, **LOBLOLLY.** *Gordonia las-anthus*. —, **RED.** *Laurus carolinensis*. —, **ROSE.** *Epilobium angustifolium*. —, **SWEET, or BAY-TREE.** *Laurus nobilis*; also an American name for *Magnolia glauca*.

**BAYBERRY.** *Myrica cerifera*.

**BDELLIUM, AFRICAN.** A gum resin obtained from *Balsamodendron africanum*; also applied to that obtained from *Ceradia furcata*. —, **INDIAN.** A resinous product of *Balsamodendron Roxburghii*, or *Amyrs Bdelium*.

**BEAD TREE.** The common name for *Melia*.

**BEAKED.** Ending in a long sharp terete, or angular point.

**BEAK-SEDGE.** A common name for *Rhynchospora*.

**BEAM TREE.** *Pyrus Aria*.

**BEAN.** The common name for *Faba*. —, **BOG.** The Buckbean, *Menyanthes trifoliata*. —, **CUJUMARY.** The tonic seed of *Ayendron Cujumary*. —, **EGYPTIAN, or PYTHAGOREAN.** The fruit of *Nelumbium speciosum*. —, **FRENCH.** *Phaseolus vulgaris*. —, **HARICOT.** The seed of *Phaseolus vulgaris*. —, **INDIAN.** An American name for *Catalpa*. —, **KIDNEY.** The common name for *Phaseolus*, especially for those kinds cultivated as esculents. —, **LIMA.** An American name for *Phaseolus lunatus*. —, **LOCUST.** The pod of *Ceratonia Siliqua*. —, **MO- LUCCA.** The seed of *Gulandrina Bondu- colla*. —, **ORDEAL, of Old Calabar.** The seeds of *Physostigma venenatum*. —, **OX-EYE.** The seed of *Mucuna urens*. —, **PICHULIM.** A commercial name for the cotyledons of *Nectandra Puchury*. —, **SACRED.** The common name for *Nelumbium*. —, **SAHUEA.** *Saja hispida*. —, **ST. IGNA- TIUS.** The seed of *Ignatia amara*, alias *Strychnos Ignatia*. —, **SCARLETRUNNER.** *Phaseolus multiflorus*. —, **TONKA, or TON- QUIN.** The seed of *Dipteris odorata*. —, **UNDER-GROUND KIDNEY.** *Arachis hypogæa*. —, **WATER.** An English name for the family of *Nelumbiaceæ*. —, **WILD.** An American name for *Ajios*.

**BEAN CAPER.** The common name for *Zygophyllum*.

**BEAN TREE, Swedish.** *Pyrus intermedia*. —, of Australia. *Casinospermum australe*.

**BEAN TREFOIL.** The common name for *Anagyris*; sometimes also applied to *Menyanthes trifoliata*, and anciently to *Cytisus Laburnum*.

**BEAR-BANE.** *Aconitum arctophonium*.

**BEARBERRY.** *Arctostaphylos*.

**BEARBIND.** The common name for *Calystegia*.

**BEAR'S BREECH.** *Acanthus*.

**BEAR'S EAR.** *Primula Auricula*.

**BEAR'S FOOT.** *Helleborus fetidus*.

**BEAST'S BANE.** *Aconitum therio- phomum*.

**BEATONIA.** A genus of bulbous *Iridaceæ*, containing a single species, *B. purpurea*, found in Mexico. This has a simple flower-stem about six inches high, a few plaited leaves, and one or two terminal flowers, which are crateriform, rose- purple, whitish and dotted with purple near the base. The perianth is very irregular, almost as in *Tigridia*; the filaments cylin- draceously connate, and the style slender, with a three-lobed stigma, the lobes of which are split and recurved. [T. M.]

**BEATSONIA.** A genus of *Frankeniaceæ*, scarcely differing from *Frankenia*, but having two styles, with globular stigmas, and a two-valved capsule, while in *Frankenia* there are three styles and a three- valved capsule. *B. portulacifolia* is one of the few plants indigenous in the island of St. Helena. [J. T. S.]

**BEAUCARNEA.** A name lately given to a genus of Agave-like liliaceous plants, till recently known in gardens under that of *Poincettia*, which, it is said, originated in a mis-spelling on a garden label of *Freycinetia*, the name of a genus of screw- pines, with which these have no affinity whatever. The few known species are natives of Mexico. They have arborescent stems, remarkable for the large bulbiform swelling which, from the earliest stages, forms at the base; these support a spread- ing terminal crown of long narrow leaves. The inflorescence in *B. recurvata* is a large terminal panicle, a yard or more in height, bearing a multitude (4,000 to 5,000) of small white fragrant flowers. The genus is very nearly allied to *Dasylirium*, being, like it, diœcious, but it differs in having the segments of the perianth more decidedly biseriate and unequal, in its more truly paniced inflorescence, and in the remarkable bulbiform base of its Dracena- like stems. The species are: *B. recurvifolia* (*Poincettia tuberculata*), which has the leaves channelled and recurved; *B. stricta* (*P. glauca*), which has plain glaucous leaves, straighter and more erect; and *B. gracilis* (*P. gracilis*), which has very straight sharp erect leaves, slightly chan- nelled in front. [T. M.]

**BEAUFORTIA.** A genus of *Myrtaceæ*, consisting of shrubs with opposite sessile leaves. The showy flowers have a calyx

with a top-shaped tube, and a limb divided into five acute segments; a corolla of five petals; stamens united into four or five parcels placed opposite the petals, the anthers attached by their base; style thread-shaped. The fruit is a capsule. These handsome flowering shrubs are natives of New Holland, and some of them are in cultivation in our greenhouses. [M.T.M.]

**BEAUMONTIA.** Under this name are included some very handsome flowering shrubs of climbing habit belonging to the order *Apocynaceæ*. The leaves are opposite. The flowers are white, large, borne in terminal or axillary corymbs, and have a calyx of five broad spreading coloured sepals, and a distended bell-shaped corolla, with a short limb divided into five erect nearly equilateral divisions. The stamens are placed on the top of the tube of the corolla, and alternate with the five lobes of the hypogynous disc; anthers arrow-shaped, adhering to the thick oblong two-cleft stigma. Ovary two-celled. Fruit a follicle, with many hairy seeds. These plants, especially *B. grandiflora*, are remarkable for their handsome flowers; they are natives of the East Indies, and are cultivated as stove plants in this country. [M.T.M.]

**BEAVER TREE.** *Magnolia glauca*.

**BECK-BEAN.** *Menyanthes trifoliata*.

**BECKEA.** A small group of South African dwarf shrubs, of the order *Bruniaceæ*, closely related to *Bruma*, differing in having a smooth instead of hairy calyx, included instead of exerted stamens, and in the fruit being crowded by the persistent calyx, the petals and stamens falling away. The species have by some been referred to *Phylla*. [T.M.]

**BECKERA.** A genus of Grasses belonging to the tribe *Panicææ*. The few species which belong to it are all natives of Abyssinia, save one, *B. nubica*, an annual, which grows wild in Nubia. [D.M.]

**BECKMANNIA.** A genus of Grasses belonging to the tribe *Phalarideæ*. The inflorescence is in close compressed spikelets; spiculae two-flowered; glumes unequal, navicular, slightly stalked at the base, obtuse, or rather obovate; pales two, nearly equal. One species only is described, *Beckmannia erucaeformis*, a native of Japan, and a very elegant grass, which proves hardy in Britain. [D.M.]

**BECLARDIA.** A synonyme of *Cryptopus*.

**BEDAGOSA.** A Brazilian name for the seeds of *Cassia occidentalis*, which are used as a substitute for coffee.

**BED'EGUAR.** (Fr.) Sweet-brain Sponge, a sponge-like gull found on the Eglantine and other roses.

**BEDFORDIA.** A genus of the Composite family, which scarcely differs from *Senecio*. Two species are known, both Tasmanian shrubs or small trees, with alternate lan-

ceolate or linear leaves, which are glossy above and covered underneath with a white tomentum, as are the branches and flower-heads. The latter are axillary and solitary, or few together, and have no strap-shaped florets. *B. salicina*, the Dogwood of Tasmania, has beautifully marked wood, suitable for cabinet-work, and is sometimes to be met with in English gardens. The genus is named in honour of the late Duke of Bedford, a great patron of horticulture and botany. [A. A. B.]

**BEDSTRAW** *Galium*; also applied to *Desmodium Apai...*

**BEEBERU** The Guianian name of *Nectandra Rodiei*.

**BEC-DE-CIGOGNE.** (Fr.) *Erodium cicutarium*. — **DE GRUE** *Erodium gruinum*. — **DE HERON** *Erodium arbutinum*. — **DE PIGEON.** *Geranium columbinum*.

**BEECH.** The English name of *Fagus sylvatica*. —, of Australia. *Tectona australis*. —, of New South Wales. *Monotoca elliptica*. —, BLUE or WATER. *Carpinus americana*. —, SEA-SIDE. A name used in Jamaica for *Erotema caribæum*.

**BEECH-DROPS.** An American name for *Epphegus*. —, FALSE. An American name for *Hypopitys lanuginosa*.

**BEECH-MAST.** The fruits of the Beech tree, *Fagus sylvatica*.

**BEEFINGS.** Apples prepared by being oven-dried and pressed flat.

**BEE-FLOWER, or BEE ORCHIS.** *Ophrys apifera*.

**BEEFSUET TREE.** *Shepherdia argentea*.

**BEEFWOOD.** The common name for *Cassurina*. Also applied, in N. S. Wales, to *Stenocarpus salignus*, and in Queensland to *Banksia compar*.

**BEE.** The common name of the excellent *Beta vulgaris*. —, CHARD or SILICILIAN. *Beta Cicla*.

**BEFARIA.** A genus of *Ericaceæ*, containing about twenty species of small and often glutinous shrubs, natives of the Alpine districts of Peru and Mexico. They have alternate often crowded entire coriaceous leaves, and bear flowers, generally of a purple colour, in terminal racemes or corymbs. The calyx is 6-7 cleft; the corolla consists of as many petals; the double series of stamens have filiform filaments, and smooth two-celled anthers dehiscing by oblique pores at the apex. The ovary has six or seven cells, each containing many ovules; the style filiform, often long and exerted; and the stigma capitate. The capsular fruit dehiscens septically. The plants of this genus are extremely beautiful; they grow at a great height on the mountains of South America, often at the very extreme of vegetation. The genus is nearly related to *Rhododendron* from which it differs in its petals being all

distinct, overlapping each other, and not being united into a tube. [W. C.]

**BEGGAR-TICKS.** An American name for *Bidens frondosa* and *B. connata*.

**BEGONIACEÆ.** (*Begoniads*.) A natural order of dicotyledonous plants, belonging to the monochlamydeous sub-class of De Candolle. Lindley places the order in his Cucurbital (Cucumber) Alliance. The order contains herbaceous plants or succulent under-shrubs. The leaves have an oblique form, and are placed alternately on the stem, having stipules at their base. The flowers have no petals, but consist of a single perianth, usually pink-coloured, which is placed above the ovary or seed-vessel. Some flowers have stamens only, others pistils only: in the former, the perianth has from two to four divisions; in the latter from two to eight. The stamens are numerous and are collected in a head. The stigmas are three, and the fruit is winged with three divisions. Some of the plants produce buds which are easily detached so as to constitute living plants. The plants are common in the East and West Indies, and South America; a few occur in Madagascar and South Africa. They are said to possess bitter and astringent qualities, and some have been used in the cure of fluxes of various kinds. In the order there are according to Klotzsch, forty-two genera; and nearly four hundred species are known. Illustrative genera:—*Barya*, *Begonia*, *Diplocnium*, *Ewaldia*, *Meserea*, and *Gireoudia*. De Candolle admits only *Casparia* and *Meserea* of Klotzsch's genera, above referred to, retaining about three hundred and fifty species in *Begonia* proper, distinguishing them by certain peculiarities of the placentas and the capsule. [J. H. B.]

**BEGONIA.** The genus whence the natural order *Begoniaceæ* derives its name. It consists of herbaceous plants found in the East and West Indies, Brazil and other parts of South America, and in Mexico. The staminate flowers have four and the pistillate five sepals. Anthers oblong, with an obtuse connective elongated at the apex; filaments short and not united. Style persistent, its branches surrounded by a continuous papillose band, which makes two spiral turns. The placentas are entire or bipartite, placed in the interior angle of the cells of the capsule. The genus is named after Michel Begon, a Frenchman, who promoted the study of botany. The plants receive the name of Elephant's-ear from the form of their leaves. The stalks of some of the species are used in the same way as rhubarb. [J. H. B.]

**BEHEN.** *Silene Behen*, *Cucubalis Behen*, now *Silene inflata*, and *Serratula Behen*.

**BEHEN BLANC.** (Fr.) *Silene inflata*. — **ROUGE.** *Centranthus ruber*.

**BEJARIA.** A synonyme of *Befaria*, a genus of ericaceous plants related to *Ehododendron*.

**BELANGERA.** A genus of Brazilian trees belonging to *Cunonaceæ*, with opposite stalked leaves having from three to five serrated leaflets; stipules caducous; racemes simple, axillary; calyx six-parted; petals none; stamens numerous, on a perigynous disk; ovary free. [J. T. B.]

**BELIS.** A synonyme of the coniferous genus *Cunninghamia*.

**BELLADONNA.** A name sometimes given to a group consisting of certain species of *Amaryllis*, of which *A. Belladonna* is the type. The genus is not generally adopted, and indeed, according to Herbert, its type is also the type of the Linnean *Amaryllis*. [T. M.]

**BELLADONNA.** *Atropa Belladonna*, the Deadly Nightshade.

**BELLADONE.** (Fr.) *Atropa Belladonna*. — **D'AUTOMNE.** *Amaryllis Belladonna*. — **DE ROUEN, or D'ETE.** *Hippeastrum vittatum*.

**BELLE DAME.** (Fr.) *Atriplex hortensis*.

**BELLE-DE-JOUR.** (Fr.) *Convolvulus tricolor*. — **DE NUIT.** *Mirabilis Jalapa*. — **D'ONZE HEURES.** *Ornithogalum umbellatum*.

**BELLENDENA.** A genus of proteaceous plants. The only species, *B. montana*, is a native of Tasmania, where it has been found on Mount Wellington. It bears a short spike of apetalous flowers of four sepals, with four free stamens rather shorter than the sepals, and a filiform style; its fruit is a nut. The plant is of humble growth, eight to ten inches in height, having crowded short-stalked wedge-shaped leaves, obsoletely three nerved with a three-toothed apex. [R. H.]

**BELLERIC.** The astringent fruit of *Terminalia Bellerica*.

**BELLEVALIA.** A genus of *Liliaceæ*, containing a few bulbous plants found in the Mediterranean region and in temperate Asia. They have the habit of some of the larger species of grape hyacinth (*Muscari*), but are distinct by having their perianth divided half way down into six folded lobes, expanding to form a prismatic bell. From the true hyacinths they differ by the perianth having an angular and not a circular section. The few leaves are radical, broadly linear; the flowers small, whitish or violet tinged with green. [J. T. B.]

**BELL-FLOWER.** The common name for *Campanula*; also applied to *Campanula Campanula*.

**BELLIDIATRUM.** A genus of the Composite family, containing but one species, *B. Micheli*, which is found in the Alps of Central and Southern Europe. The plant without close examination might be readily taken for a common daisy (*Bellis*), but can be easily distinguished from that genus by the presence of a copious pappus of rough hairs, the daisy having no pappus at all. [A. A. B.]

**BELLIS.** The Daisy: the favourite flower of the poets of nature, from Chaucer to Burns; the first which children learn to call by name, and thenceforth love for evermore. The 'bonnie gem' of the latter poet was regarded by 'the firste fynder of our fayre langage' with such deep feeling, that the reader cannot but be pleased to have the opportunity of calling its characters from the following extracts:—

'And lening on my elbowe and my side  
The longd dale I shope me for to abide,  
For nothing ellis, and I shall nat lie,  
But for to lookun upon the Daisie,  
That well by reson men it calld male  
The Daisie, or els the eye of the dale,  
The emprise, and the floure of flours alle.

'Whan that the sunne out of the south  
gan west,  
And that this floure gan close and gon to  
rest  
For darknes of the night, the which she  
drede,  
Home to my house full swiftly I me  
spede  
To gone to rest, and cry for to rise  
To seene this floure to sprede as I devise.

He falls asleep, and, in his dream, the Queen of Love appears, 'clad in roiall habite grene,' with a fret of gold on her head—

'And upon that a white coroune she bere  
For all the worldis sight as a Daisie  
Icrounid is, with whitte levis lite,  
So were the flouwis in her crounid white.  
For of a perle fine orientall  
Her whitte coroune was imakid all,  
For which the whitte coroune above the  
grene  
Ymade her like a Daisie for to seue  
Considrid eke her fret of gold above.'

'The flour  
Icrounid al with white, as men male se,  
And Mars egave her a coroun red parde,  
Instede of rubies set among the white.'

And as the Queen of Love was crowned with the flowers which the poet did 'love and drede,' so the fairest land he had ever seen was

'a lannde of white and grene;  
The grounde was groue, ypendrid with  
Daisye.'

The daisy again fills a prominent place in the 'Floure and the Leaf,' where the band of knights and ladies

'found a tuft that was  
All oversprad with flours in compas,  
Whereto they enclindid everifone  
With grete reverence, and that full  
humily:

And at the last mere this began anon  
A lady for to sing right womanly  
A bargaret in praising the Daisie,  
For (as methought) among her notis  
swete,

She said, "Si douce est la Marguerite!"

Marguerite, the reader need scarcely be informed, is the French for 'a pearl,' and 'a daisy.'

[C. A. J.]

**BELLUM.** The species of this genus are five in number—one of them, *B. cordifolium*, found in Spain, and the others in Southern Italy, and the neighbouring islands. They are nearly related to the common daisy (*Bellis perennis*), and all of them are plants of a very similar appearance, but they differ in having a pappus of six to eight broad scales, torn at the apex, alternating with an equal number of long scabrous bristles.

[A. A. B.]

**BELLWORTS.** An English name for the group *Campanulaceae*. The term Bellwort is also used in America for *Uvularia*.

**BELLYING.** When a round body is more prominent on one side, or at one point, than at another.

**BELMONTIA.** A genus of *Gentianaceae*, which may be recognised by the calyx, which is more or less deeply divided, five-parted, with prominent angles or wings; a regular five-cleft corolla, with an almost cylindrical tube; five stamens included within the corolla; a stigma, with two roundish club-shaped lobes; and a two-celled capsule, whose placenta ultimately divides into four pieces. The plants are natives of Southern Africa.

[M. T. M.]

**BELOANTHERA.** A genus of *Mesembryaceae*, founded on a herb from Java, which has a procumbent rooting stem, nearly sessile alternate leaves, a glandular hairy calyx, five very small white petals, five stamens, and two deflexed styles, with violet stigmas.

[J. T. S.]

**BELOPERONE.** A considerable genus of *Acanthaceae*, from tropical America, containing many species of beautiful shrubs, with large purple or blue flowers, borne on short secund axillary or terminal spikes, and having the bracts frequently brightly-coloured. The calyx is deeply five-cleft, the corolla gaping, the upper lip concave, the lower trifid. The two stamens are inserted in the corolla tube; the anthers are spurred at the base. The two-celled ovary has two ovules in each cell; the stigma is subulate. The lower half of the capsule is unguiculate, without seeds, the upper portion containing four coloured discoid seeds.

[W. C.]

**BELOTES.** The Spanish and Italian name for the edible nuts or acorns of *Quercus Gramuntia*.

**BELOTIA.** A genus of the Lime-tree family (*Tiliaceae*), and nearly allied to *Grewia*, but differing from that genus in having a two-celled capsule, with many seeds in each cell; while the fruit of *Grewia* is from four to eight-celled, each cell containing but one seed. Only one species, *B. grewiaefolia*, is known. This is found in Mexico and Cuba. It is a small tree, having the younger branches thickly clothed with dense starry hairs. Its leaves

are alternate, stalked, elliptical in form, and acute, the upper surface nearly smooth, and the lower covered with white starry pubescence. The flowers are white, almost the size of those of the lime tree, and arranged in racemes in the upper axils of the leaves. The genus bears the name of Dr. Charles Belot, a distinguished surgeon of Havannah. [A. A. B.]

**BELVE'DÈRE.** (Fr.) *Kochia scoparia*.

**BELVISIACEÆ.** A group of three or four tropical species, whose affinities had been long misunderstood, owing to the imperfect specimens which had been obtained. They are now, however, better known, and have been shown to constitute a small family closely allied to *Myrtaceæ*, or even a tribe only of that family, of which they have the inferior several-celled ovary, the numerous stamens turned inwards in the bud, the fruit and the seeds. They differ in their plaited petals, united into a rotate lobed corolla, and in their stamens, united in concentric rings, of which the outer ones are converted into barren stamulodia. They are all shrubby or arborescent, with alternate leaves and axillary almost sessile flowers. They form two genera: *Napoleonia* (unwarrantably altered by Deavaux, for political reasons, to *Belvisia*), from tropical Africa; and *Asteranthos*, from North Brazil.

**BELVISIA.** A group of ferns, separated by Mirbel from *Acrostichum*, as formerly understood. The species referred to it have little or no affinity, according to modern views of classification, but are included severally in *Acrostichum*, *Asplenium*, *Ceratopteris*, *Hymenophyllum*, and *Schizaea*. The characters relied on were: the fructification occupying the whole space between the edge of the frond and the costa, so as to form a line on each side; and covered by a recurved membrane, attached to the edge of the frond; but the proposed species have only an external resemblance, even in these particulars. The name *Belvisia* is also a synonyme of *Napoleonia*. [T. M.]

**BENÇAO DE DEOS.** The Brazilian name for the esculent flowers of *Abutilon esculentum*.

**BENCOMIA.** The species of this genus, which belongs to that section of the Rose family called *Sanguisorbeæ*, are both found in Teneriffe. They are low perennial shrubs, with unequally pinnated leaves, and pectinately toothed stipules. Their flowers are male and female, on different plants, and arranged in long catkin-like bracted spikes. The tube of the calyx, when mature, has the appearance of a berry, and encloses two to four achenes. The genus is nearly allied to that of the garden burnet (*Poterium*), but differs from it in having dioecious flowers, as well as in the long spikes. *B. caudata* was introduced to English gardens in 1779, but is seldom to be met with. The flowers are greenish, tinged with purple, and very

small. The genus bears the name of Bencomi, the last king of Teneriffe. [A. A. B.]

**BENGAL ROOT.** The root of the Yellow Zedoary, *Zingiber Carumuniar*.

**BENINCASA.** This name is applied to a genus of Cucurbitaceous plants, in honor of Count Benincasa, an Italian nobleman. The plants are herbs, with hairy musk-scented leaves, climbing stems, and simple tendrils. The flowers are solitary, yellow, polygamous, and monoecious. They have a calyx with short wide lobes, wavy and dentate at the margin; a corolla, with five roundish spreading lobes, wavy at the margin; stamens in three bundles, diverging, rudimentary in the females, the filaments short and wide, and the anthers very irregular in shape; stigma thick and irregular; fruit ovate, cylindrical, downy, the seeds thickened at the margin. The unripe fruits of *B. cerifera*, the White Gourd of India, are universally employed by the natives in their curries. [M. T. M.]

**BENJAMIN BUSH.** *Dioscorea odorifera* n.

**BENJAMIN TREE.** *Stryax Benzoïn*. The name is also sometimes applied to *Ficus Benjamin*, and to *Benzoïn odoriferum*, the *Laurus Benzoïn* of Linneus.

**BENNET, HERB.** *Geum urbanum*.

**BENNETTIA.** See *Galearia*.

**BENOÎTE COMMUNE.** (Fr.) *Geum urbanum*.

**BENTHAMIA.** A genus of epigynous Exogenous plants, belonging to the natural order *Cornaceæ*, distinguished by having the calyx segments small, four-toothed; petals four, fleshy and cup-shaped; stamens four; style one; fruits small drupes growing together and forming a large berry resembling the fruit of *Arbutus*, and red when ripe. The leaves are opposite, and bear no inconsiderable resemblance to those of the Cornelian cherry. *B. fragifera* was introduced to English gardens about the year 1833, and is now to be found in some good collections; but being a native of northern India, it is rather tender, and frequently hurt during severe winters, unless protected, especially in the mildland and southern counties. [D. M.]

**BENTE.** A common country name for the dried stalks or culms of various grasses occurring in pastures, especially those of *Agrostis* and *Cynosurus*.

**BENZOÏN.** A genus of *Lauraceæ*, inhabiting the damp shady woods of North America, and found also in Nepal. It has dioecious involucreted flowers; the males with a calyx of six equal permanent segments, and nine stamens in three rows, and females smaller than the males, with fifteen to eighteen sterile stamens, amongst which smaller spatulate bodies are dispersed. The ovary is one-ovelled with a single ovule, and the style short with a two-lobed stigma. There are in the male flowers two or three rows of glands, six to

nine in number, with a uniform compressed head, alternating with the rows of stamens. The fruit is succulent, seated on the permanent six-lobed calyx. *B. odoriferum*, which furnishes an aromatic stimulant tonic bark, is a bush of eight to ten feet high, with oblong or elliptic wedge-shaped leaves, and small yellow flowers on naked umbels appearing before the leaves. The berries are said to have been used in the United States during the American war, as a substitute for salispe; and they yield an aromatic stimulant oil. [T. M.]

**BENZOLIN.** The gum-resinous or balsamic exudation of the Benjamin tree, *Stryx Benzoin*. A milky juice resembling benzoin is also obtained from *Terminalia Benzoin*. —, **FALSE.** A name given in Bourbon to *Terminalia mauritiana*, which furnishes a resinous gum resembling benzoin.

**BEQUETTE.** (Fr.) *Delphinium Ajacis*.

**BERAR** '*Caladium*' *costatum*, which is said to supply an edible root in Sumatra.

**BERBERIDACEÆ.** (*Berberids*.) A natural order of Exogenous plants, belonging to the Thalamifloral sub-class of DeCandolle. Lindley includes the order in his Berberal Alliance along with vine-woods and fumewoods. The plants of this family are shrubs or herbaceous perennials, with alternate compound leaves, which are often spiny. Sepals three, four, or six in a double row; petals equal to sepals in number, or twice as many; stamens equal in number to petals and opposite to them; anthers having two lobes, each opening by a valve, which rolls up from the bottom to the top. Ovary solitary and one-celled; stigma orbicular. Fruit, either a berry or a capsule, with one, two, or three seeds. These plants are found in the mountainous parts of the Northern Hemisphere, and of South America as far as the Straits of Magalhaens. They are common in the northern provinces of India. None occur in Africa, Australasia, or the South Sea Islands. They possess acid, bitter, and astringent qualities. The fruit of some is used as a preserve, and sometimes eaten in a fresh or dried state. Oxalic acid occurs in some of the species. The stem and bark of several berberries are used in dyeing yellow. The astringent substance called Lycium of Dioscorides is supposed to be furnished by the root of various species of berberry; and a preparation of a similar kind is much used as a febrifuge in India. The pinnate-leaved berberries in cultivation form the sub-genus *Nahonia*. In the order there are twelve genera and 110 species. See *Berberis*, *Spineadum*, *Leontice*, *Nandina*, *Diphylla*, and *Jeffersonia*. [J. H. B.]

**BERBERIS.** The typical genus of the family *Berberidaceæ*. It consists of shrubs found chiefly in the temperate parts of Europe, Asia, and America, having the leaves simple or pinnate, the primary ones sometimes abortive or changed into simple or variously divided spines, with a tuft of

smaller secondary leaves in their axil. The flowers consist of a six to nine-leave deciduous calyx of coloured sepals, disposed in two to three series: six hypogynous clawed petals opposite the interior row of sepals, and having two glands inside at the base; six stamens opposite the petals, and opening by valves; and a one-celled ovary containing two to eight erect ovules, and surmounted by a peltate stigma on a very short style. This grows into a one-celled ovary containing from one to eight seeds. The pinnate-leaved species are sometimes separated, especially in gardens, under the name of *Nahonia*, these have the glands at the base of the petals frequently obsolete, and are great ornaments of our shrubberies. [T. M.]

The common Berberry, or *Berberis*, *B. vulgaris*, forms a deciduous shrub, attaining the height of eight or ten feet. It is found wild in Britain as well as most other parts of Europe, and is also commonly met with in a wild state in North America, and particularly in New England; but it is very doubtful whether the plant is really indigenous to that continent or was carried there by the early settlers, and disseminated through the agency of birds. The distinguished botanists Torrey and Gray affirm that it was introduced; and this opinion is strengthened by the fact of the species not being found in Iceland and Labrador, nor in the eastern parts of Siberia. The Berberry forms a compact bush, composed of numerous very spiny shoots springing from the base, which are covered with a whitish bark, the wood itself being of a fine yellow. The leaves are small, obovate, toothed, and ciliated on the margin, and of a pleasant green; the flowers are yellow, appearing in May. The berries are in pendulous racemes; their colour is generally bright red, but in some varieties they are purple or yellowish-white. Occasionally plants are met with, the berries of which have no seeds; but such do not constitute a permanent variety, for stoneless berries are only found on old plants; and it has been proved that young suckers taken from them and planted in fresh soil, fruit with perfect seeds. The fruit is too acid for use in its natural state; but it makes excellent refreshing preserves, for which Rouen is particularly celebrated. It is likewise candied; and when green is sometimes pickled in vinegar. The inner bark affords a bright yellow dye. The roots, which are of deep yellow colour throughout, boiled in an alkaline ley, yield a yellow dye, used in Poland for colouring leather. [R. T.]

The bark of the Berberry, of which a decoction was made, was formerly much celebrated as a remedy in jaundice, but it has long since been discarded from modern practice, as its claims as a medicinal plant only rested upon the doctrine of similitudes, which assumed that nature when she made a plant, impressed upon it some sign to point out its curative properties to those who properly sought such knowledge. In this way it was supposed that as the patient's skin in jaundice is yellow, so the

yellow bark of the Berberry indicated it as a remedy for this diseased condition.

Another popular notion with respect to this shrub is, that it is the cause of blight or rust in corn. This has arisen from the circumstance that the Berberry is itself frequently attacked by a species of epiphyte—the *Acidium Berberidis*, in which the leaves appear to be covered with spots of a brightish red colour, whilst wheat is subject to another epiphyte, the *Puccinia graminis*. [J. B.]

[Recent investigations tend to confirm this notion, it having been shown that *Puccinia graminis* will not reproduce itself, but that if its spores are sown upon the leaves of the Berberry, they give rise to *Acidium Berberidis*. The spores of the *Acidium*, on the other hand, do not reproduce itself, but the *Puccinia*: thus furnishing a very striking illustration of the doctrine of alternation of generations. J. Br.]

**BERBERRY.** *Berberis vulgaris*, sometimes called Barberrry. — **OPHTHALMIC.** *Berberis Lycium*.

**BERCE.** (Fr.) *Horaeolum Aphendylum*.

**BERCHEMIA.** Twining, or erect, deciduous shrubs, belonging to the order *Rhamnaceae*. *B. volubilis* is a native of Carolina and Virginia, in deep swamps near the coast. According to Pursh it ascends the highest trees of *Taxodium distichum*, in the Dismal Swamp, near Suffolk, in Virginia; and it is known there by the name of Supple Jack. The stems twine round one another, or any object which they may be near. The flowers are small and of a greenish-yellow colour; and in America they are succeeded by oblong violet-coloured berries. It will grow in any common soil; and is well adapted for hedges or trellis-work. It rarely, however, exceeds the height of eight or ten feet in this country, owing probably to the neglect of planting it in wet peaty soil. It was introduced in 1714. The other species are not much cultivated. [C. A. J.]

**BERGAMOT.** *Mentha citrata* or *odorata*. — **WILD.** An American name for *Monarda fistulosa*.

**BERGAMOTTE.** (Fr.) The Lime, *Citrus Limetta*.

**BERGERA**, one of the genera of *Aurantaceae*, is so named in honour of a Danish botanist. The genus consists of a few species of small trees with pinnate leaves, small white flowers in terminal panicles, with a five-cleft calyx, five spreading petals, ten stamens with ovate anthers, and filaments flattened at the base. The fruit is one-celled and one-seeded. *B. Kingii* is known in India as the Curry-leaf tree, as the natives flavour their curries with its aromatic fragrant leaves. The leaves, root, and bark are likewise used medicinally. The wood is hard and durable, and from the seeds a clear transparent oil, called Simbolee oil, is extracted. [M. T. M.]

**BERGIA.** An unimportant genus of

herbaceous plants belonging to the order *Elatinaceae*. All the species are natives of the East Indies, Java, or the Cape of Good Hope, where they grow in moist places, such as rice fields, which are irrigated the greater part of the year. Dr. Wight says, that in India the little *B. amantoides* bears a Tamil name equivalent to Water-fire, which, as Lindley observes, seems a curious coincidence with the word Water-pepper, given in English to *Elatine*, and seems to indicate a popular belief in these plants possessing some acridity. [C. A. J.]

**BERGSMIA.** A genus of the *Flacourtiaceae* family, containing but one species, *B. javanica*, which is a native of Java, and is described as being a large tree with alternate or opposite stalked leaves, which are entire, from three to five inches long, and lanceolate in form, their upper surface smooth, and of a whitish colour beneath. The flowers are arranged in axillary racemes and have a three-parted calyx, five petals, and four or five stamens, the stalks of which are united. The fruit is not known. The genus bears the name of C. A. Bergsma, a professor of botany in Holland. [A. A. B.]

**BERLANDIERA.** A genus of the Compositae family, nearly related to *Silphium*, but differing in the wingless achenes of the ray florets, which are arranged in a single series, and are adherent to the large interior involucre scales. The five known species, distributed over the S. W. States, Texas, and Mexico, are pretty perennial herbs one to two feet high, the stems slightly branching above and terminating in solitary stalked yellow-rayed flower-heads an inch or more across, while the alternate heart-shaped ovate-oblong, or in one case pinnatifid, leaves have notched margins, and are clothed underneath with a white velvety down. The involucre scales are foliaceous (like those of the *Dahlia*) and in three series; the strap-shaped ray-florets have a pistil only; the tubular disc ones are sterile and enveloped by the dilated chaffy scales of the receptacle; and the flattened obovate achenes have a pappus of two short awns. The genus bears the name of M. Berlandier, an American botanist, who collected largely in Texas. [A. A. B.]

**BERLE.** (Fr.) *Stium*.

**BERMUDIENNE A' PETITES FLEURS.** (Fr.) *Sieyrrinchium Bermudiana*.

**BERNHARDIA.** A synonym of *Pelletium* and *Tinosporia*.

**BERRIED.** The same as *Baccate*.

**BERRY.** See *Bacca*.

**BERRYA.** A genus of the Lime-tree family (*Tiliaceae*). But one species, *B. Ammonia*, is known; it is a tree with alternate stalked heart-shaped leaves, which are smooth and have from five to seven nerves radiating from the base. The flowers are white and very numerous,

arranged in terminal or axillary panicles; their calyx one-leaved, splitting irregularly into three or five divisions, and about half as long as the petals, which are five in number and narrow oblong in shape. The fruit is a three-celled capsule ornamented with six membranaceous wings covered with silky hairs. The seeds, one to four in each cell, are covered with short rigid hairs which readily enter the skin and produce as much painful itching as those of the Cowitch plant *Mucuna*. It is a native of Ceylon, the Philippines, and Tropical Australia. In the former place it becomes one of the largest

in the island for making oil casks. Being light and strong, it is employed in the construction of the Massoola boats of Madras. It is exported in large quantities under the name of Trincomalee wood. The native name is said to be *Ammonilla*. The genus is named in honour of the late Dr. Andrew Berry, a Madras botanist. [A. A. B.]

**BERTEROA.** A genus of European and temperate Asiatic Cruciferous plants, allied to *Parsetia*, of which it ought to be considered as a section, as it merely differs from it by having the sepals bulging at the base, the petals bifid, and the valves of the pouch convex, without a nerve; in habit the two genera agree. From *Alyssum*, with which it is frequently associated, it differs by the bifid petals and swollen pouch, which is usually more elongated. *B. incana*, a common European plant, has small white flowers, and its stems and leaves are covered with close white stellate hairs. [J. T. S.]

**BERTHELOTIA.** A genus of the Composite family, named in honour of Sabine Berthelot, joint editor with Mr. P. E. Webb in their great work on the flora and fauna of the Canaries. But one species is known, which is a small shrub with alternate lanceolate rigid entire leaves, terminated by a little point. The flower-heads are arranged in dense corymbs at the apices of the branches, and the florets are purple in colour, those of the ray female and those of the disc having both stamens and pistil. The pappus is white, pilose, and the hairs arranged in one series. All the parts of the plant are covered with short pubescence, which gives it a whitened appearance. The plant is common in the Banda district of India, the Punjab and Scinde, as well as in Senegambia. [A. A. B.]

**BERTHOLLETIA.** A genus of *Lecythidaceae*, of which only one species, *B. excelsa*, which yields the Brazil-nuts of our fruit shops, is known. This tree is a native of Guiana, Venezuela, and Brazil; it forms large forests on the banks of the Amazon and Rio Negro, and likewise about Esmeraldas on the Orinoco, where the natives call it 'juvia.' The tree is one of the most majestic in the South American forests, attaining a height of 100 or 150 feet, with a smooth cylindrical

trunk about three or four feet in diameter, and seldom having any branches till near the top. It has bright green leaves about two feet long and six inches wide, entire or undivided, and placed alternately upon the branches. The flowers have a two-parted deciduous calyx, six unequal cream-coloured petals, and numerous stamens united into a broad hood-shaped mass, those at the base being fertile and the upper ones sterile. The fruit is nearly round, and about six inches in diameter, having an extremely hard shell about half an inch thick, and containing from eighteen to twenty-four triangular wrinkled seeds, which are so beautifully packed within the shell that when once disturbed it is impossible to replace them. When these fruits are ripe they fall from the tree and are collected into heaps by troops of Indians called *castanhieros*, who visit the forests at the proper season expressly for this purpose; they are then split open with an axe, and the seeds (which are what we call Brazil-nuts) taken out and packed in baskets for transportation to Para in the native canoes. Brazil-nuts form a considerable article of export from the port of Para (whence they are sometimes called

*Bertholletia excelsa.*

Para nuts), about 50,000 bushels being annually sent to this country alone. Besides their use as an article of dessert, a bland oil, used by watchmakers and artists, is obtained from them by pressure. And at Para the fibrous bark of the tree is used for caulking ships, as a substitute for oakum. [A. S.]

**BERTOLONIA.** A genus of *Melastomaceae*, containing dwarf or procumbent herbs, natives of the dense forests of Brazil. Leaves opposite, stalked, heart-shaped, ciliated, with five or more ribs; flowers nearly sessile in cymes; petals five, white rose-coloured or purplish; stamens ten; ovary free, three-celled; capsule three-winged. *B. maculata* is a pretty

little creeping hot-house plant with spotted leaves, purple beneath. [J. T. S.]

**BERTYA.** A genus of the Spurgewort family (*Euphorbiaceæ*) composed of a number of small resinous shrubs much like the rosemary in appearance and habit. Their leaves are alternate, crowded on the branches, and linear in form, their margins entire and curved backwards. Their flowers are solitary in the axils of the leaves, those on the lower part of the stem male, the upper ones female; they are small, have no corollas, and without being looked for would be easily passed by. The leaves of most of them are covered with minute starry hairs of a white colour. Five species are known, all natives of Eastern Australia and Tasmania. The genus is named in honour of Count L. de Lambertye, a patron of horticulture in France, and the name is shortened to *B. rya* because of an already existing genus called *Lambertia*. [A. A. B.]

**BERULA.** Under this name is included a small section of the Linnean genus *Sium*. *B. angustifolia*, particularly known as the Narrow-leaved Water-paranip, is a native of the whole of Europe and a great part of Asia, growing in ditches and rivulets. The roots are fibrous, and send out stolons from the crown; the leaves are smooth, pinnate, and unequally lobed and serrated; the flowers, which are small and white, are either terminal or grow in umbels opposite the leaves, and are all stalked. [C. A. J.]

**BESCHORNERIA.** A genus of agave-like *Amaryllidaceæ* plants, related to *Litsea* and *Fouquieria*, from which it differs in having tubulose flowers, the former also differing in its exserted stamens, and the latter in its habit. The flowers consist of a deeply six-parted perianth, the segments of which are linear-spathulate, tubulose, connivent, sometimes slightly spreading at the point. There are six stamens which are about as long as the perianth; and an inferior and somewhat club-shaped ovary, terminated by a long slender style and small stigma. *B. tubiflora* is a stemless plant with a tuft of linear sword-shaped acuminate leaves, and an erect scape supporting a many-flowered raceme of purplish-green flowers. *B. yuccoides*, another species of considerable beauty, has also a radial tuft of thickish lanceolate pointed leaves, a foot and a half long, and a tall slender coral-red scape three to four feet high, the upper half of which forms a drooping panicle of slender branches of the same rich coral-red, springing from deep rose-coloured bracts, and supporting a short pendent raceme of bright green flowers. It is indeed a most striking plant, the coral-red scape and panicle, the graceful slender drooping branches, and the racemes of large pendent green flowers, which in shape are not much unlike those of some long-flowered *Fuchsia*, but of a dark yellow green tinged with red, rendering it very ornamental, the more so as it

continues a long time in blossom. The species are natives of Mexico. [T. M.]

**BESENNA.** The Abyssinian name of *Albizia anthelmintica*, and at one time adopted as the scientific name of the plant, which was then imperfectly known.

**BESHAN.** The Balm of Mecca, *Balsamodendron Opobalsamum*.

**BESLERIA.** A genus of erect branching undershrubs, abundant in the forests of tropical America, and belonging to the section of *Gesneraceæ* which have albuminous seeds. They have opposite petiolate and fleshy leaves, with prominent nerves and veins, and axillary peduncles, with one or many flowers. The calyx is free, five-cleft, and reddish coloured; the corolla is campanulate, and sub-equally five-cleft. The four didynamous stamens, along with the rudiment of the fifth, are inserted in the tube of the corolla; the anthers are two-celled. The one-celled ovary is free, surrounded at its base by a fleshy ring without glands, and has two two-lobed parietal placentæ, to which are attached numerous anatropal ovules; the style is simple and bifid; the fruit is a berry filled with the fleshy placentæ, and numerous small obovate seeds, with very short cotyledons. [W. C.]

**BESSERA.** A genus of *Liliaceæ* bulbs, found in Mexico, the species of which have narrow linear leaves, and umbel-bearing flower scapes. The perianth is bell-shaped, six-parted, furnished with six stamens, which are connate below into a cylindrical coronet, and having a sessile ovary, containing numerous ovules, lying in two rows in the cells, the style being terminated by a capitate-depressed obscurely three-lobed fringed stigma. *B. elegans*, one of the best known of the few species, produces a pair of radical leaves, which are erect for two-thirds of their length, and then become pendulous; they are one to two feet long, semicylindrical, smooth and hollow. The scape, also smooth and fistular, is solitary, erect, taller than the leaves, and bears a terminal umbel of from three to sixteen drooping flowers of an orange-red colour, and having a turbinate bell-shaped tube, a moderately spreading limb of six nearly equal oblong-obtuse segments, and a cluster of six green stamens on long red filaments projected considerably beyond the limb, and united at the base for half their length into a six-ribbed tube. [T. M.]

**BETA.** A genus belonging to the natural order *Chenopodiaceæ*, a group comprising various genera of coarse weedy-looking plants, among which *Beta* is one of the most remarkable, on account of its roots and leaves being valuable both for culinary and agricultural purposes. It is a genus with hermaphrodite flowers, in which the five-parted urceolate perigone becomes hardened at the base, the segments merely shrivelling up. There are five stamens inserted in a fleshy ring oppo-

site the limb segments, and the depressed one-celled ovary becomes a one-seeded utricle.

The Common Beet, *Beta vulgaris*, is a native of the South of Europe, and although cultivated by the ancient Romans, and much esteemed by epicures, it was not introduced into this country until 1656. It is a hardy biennial, with large erect succulent leaves, generally of a deep reddish purple colour; but that for which it is most valued is its fleshy root, which varies in form from that of a carrot to a flat round turnip. The long-rooted sorts are preferred; they are usually about a foot or more in length, and from two to four inches in diameter at the top, from which they taper to a long point, and are prized in proportion to their being wholly of a deep blood-red colour when cut. In France and Germany, beet root is far more extensively used than in England; and, when properly dressed, it is generally considered to be a wholesome and nutritious vegetable. Boiled and sliced, it is eaten cold, either by itself or mixed in salads. It is also excellent with vinegar as a pickle, and is capable of being made into a conserve. There are many varieties in cultivation, which do not differ materially from one another, except in the colour of their roots and leaves.

A variety of Beet is grown on the continent, under the name *Betterave à Sucre*, from which sugar nearly equal to that from the cane is extracted, as well as a powerful spirit.

The White, or Sicilian Beet, *Beta Cicla*, as its name imports, is a native of Sicily, near the sea coast, as well as the shores of Spain and Portugal, from whence it was introduced in 1570. It is a biennial, and is grown solely for its leaves, which are either put into soups, or dressed like spinach. In France they are often mixed with sorrel, to lessen its acidity. The ancient Greeks used to eat the leaves of beet in preference to lettuce, and blanched them by laying a tile over the plant, as some gardeners do at the present day to blanch endive.

The large White, or Swiss Chard Beet, *Beta Cicla* var., is a very distinct variety, remarkable for the thick midribs and stalks of its large upright leaves. It is the

same, or asparagus; but unless it is properly dressed, it has a peculiar earthy taste, and on this account it is not generally relished in this country.

The Sea Beet, *Beta maritima*, a perennial, which grows wild on the sea coast in various parts of Britain, is occasionally used as spinach or greens in situations where it is plentiful. [W. E. B.]

The Sea Beet is chiefly remarkable for the changes which it undergoes in cultivation, as from it have been produced the different varieties of Garden Beet, and Mangold Wurzel. If we examine the

which the roots and foliage are highly tinged with a purple colour, whilst others incline to a yellowish-green hue. These two varieties are the initiatives of the red, and the white beet, and also of the red, orange, and white mangold wurzel. With respect to those forms which are cultivated for their roots, the size to which they have been brought is remarkable; but it should be observed, with regard to the white beet, which is cultivated for the midrib of the leaves, that the roots are usually much forked, and, indeed, are not greatly better in form than those of the woody wild examples, which, however, by being cultivated with a view to the root alone, attain a compact shape and large size. [J. B.]

BETEL. The fruit of *Areca Catechu*.

BETOINE. (Fr.) *Stachys Betonica*.

—AQUATIQUE. *Scrophularia aquatica*.

BETONICA. An old Linnæan name for various plants, now referred to *Stachys*. *B. officinalis*, or *Stachys Betonica*, is the Wood Betony of the herbals. [T. M.]

BETONY. The English name for the species sometimes separated from *Stachys* under the name *Betonica*; also *Tenacrium betonicum*. —, WATER. *Scrophularia aquatica*. —, WOOD. *Stachys Betonica*.

BETTE. (Fr.) *Beta maritima*.

BETTERAVE. (Fr.) *Beta vulgaris*.

BETULACEÆ. (*Birchacorts*.) A natural order of Exogenous plants, belonging to the Monochlamydeous sub-class of De Candolle, and to the Amental or catkin-bearing alliance of Lindley. They are trees or shrubs, having alternate, simple, stipuled leaves, often with the primary veins running straight from the midrib to the margin. The flowers are in catkins, some having stamens only, others pistil only; and they have scales in place of a perianth or floral envelope. In the alder, however, there is a four-leaved perianth. The stamens are opposite the scales. The ovary is two-celled, with a single pendulous ovule in each cell; stigmas two. The fruit is dry, does not open, is one-celled and one-seeded. The plants are found in the woods of Europe, Northern Asia, the Himalayas, and North America; they also inhabit the mountains of Peru and Columbia, and the Antarctic regions. They are usually timber trees, with deciduous leaves. Their bark is used as an astringent for gargles, and for dyeing and tanning; it also possesses tonic qualities, and is occasionally employed as a substitute for paper, and for making boats. *Betula alba* is the common birch. Its sap contains sugar, and, by fermentation, yields a kind of wine. The empyreumatic oil of the birch has been recommended in various affections; it is used in the preparation of Russian leather, and gives to it a peculiar odour. The alder, *Alnus glutinosa*, grows in moist places; the wood resists well the action of water, and has been used for the piles of

bridges. The Rialto of Venice is built on alder piles, and so are many houses in Amsterdam. Sabots are made of the wood. There are two genera, *Betula* and *Alnus*, and upwards of sixty species. [J. H. B.]

**BETULA.** The Birch. Trees or shrubs inhabiting high latitudes in the northern hemisphere, or, when found in temperate regions, growing principally in rocky mountainous situations. They are characterised by slender, often drooping branches, which are covered by a smooth durable bark: by small leaves possessing little succulency, and in their nature astringent and aromatic; and by having their fructification at the same time, with the leaves in catkins of two kinds, barren and fertile, both on the same tree.

The Common Birch, *B. alba*, pronounced by the poet Coleridge—

'most beautiful

Of forest trees, the Lady of the Woods'—

is remarkable for its lightness, grace, and elegance, nor less so for its hardness; standing in no need of protection from other trees in any stage of its growth, and living on the bleak mountain side and other exposed situations from which the sturdy oak shrinks with dismay. It is a native of the colder regions of Europe and Asia. Throughout the whole of the Russian empire it is more common than any other tree, being found in every wood and grove from the Baltic sea to the Eastern ocean, and frequently occupying the forest to the exclusion of all other arboreal plants. It grows from Mount Etna to Iceland: in the warmer countries being found at a high elevation among the mountains, and varying in character according to the temperature. In Italy it forms little woods at an elevation of 6,000 feet. On some of the highlands of Scotland it is found at the height of 3,500 feet. In Greenland it is the only tree, but diminishes in size according to the decreased temperature to which it is exposed. It is a tree of rapid growth, especially when young; and as it is little affected by exposure, it forms an excellent nurse for other trees. The soil which it prefers is turf over sand, and in such situations it attains maturity in about fifty years; but it seldom exceeds fifty feet in height, with a trunk from twelve to eighteen inches in diameter. The bark possesses the singular property of being more durable than the wood which it encloses. Of this the peasants of Sweden and Lapland take advantage, and, shaping it like tiles, cover their houses with it. The wood is white shaded with red, and, if grown in a very cold climate, it lasts a long while. The highlanders of Scotland employ it for all purposes for which wood is available: the branches are used as fuel in the distillation of whisky; the spray for thatching, and for smoking hams and herrings; the bark for tanning leather; and the leaves for bedding. In Russia, an oil is extracted from the bark, which is used in the prepa-

ration of Russian leather, to which it not only imparts a fragrant odour, but renders it durable, preventing it from becoming mouldy, and repelling insects. The variety known as *B. pendula* differs from the common species only in having the branches pendulous, smoother, and more slender.

*B. nana* is found in Scotland, and in all the northern countries of continental Europe and America. It is a low wiry shrub, rarely exceeding three feet in height, with numerous round notched leaves, which are beautifully veined.

The Paper Birch, *B. papyracea*, so called from the brilliant white colour of the bark of young trees, is an American species no less valuable than the common birch, and attains a far larger size. By the Indians and French Canadians the durability of the bark is turned to good account. The Canadians select a tree with a large and smooth trunk; in the spring two circular incisions are made quite through the bark several feet from each other. Two vertical incisions are then made on opposite sides of the tree; after which a wooden wedge is introduced, by which the bark is easily detached. These plates are usually ten or twelve feet long, and two feet nine inches broad. To form a canoe, they are stitched together with the fibrous roots of the Canadian spruce. The seams are coated with resin. Great use is made of these in long journeys into the interior of the country; they are very light, and are easily carried on the shoulders from one lake or river to another. A canoe calculated for four persons weighs from forty to fifty pounds. Some are made to carry fifteen passengers. Numerous other species of birch are known to botanists, all of which approach more or less in character those described above.—French *Bouleau*, German *Birke*.

Plate 14, which is a view in Kamtschatka, represents a birch forest as seen in the distance. [C. A. J.]

**BEURRE.** A general name applied to a class of dessert Pears, which have their flesh of what is called a buttery texture, as indeed the name itself indicates.

**BEURRE DE SPERGULE.** (Fr.) *Spergula arvensis*.

**BEURRE.** (Fr.) *Heperia matronalis*

**BEYCHE SEED or NUT.** A Siamese name for *Strychnos nux-vomica*.

**BEYRICHIA.** A genus of *Scrophulariaceae*, containing a few species of herbaceous plants from Brazil and Guiana. They have opposite ovate leaves, and axillary flowers, on very short pedicels, either lax or in dense leafy spikes. The calyx is five-parted, the upper segment being ovate, and the four lower ones narrow. The upper lip of the corolla is emarginate, the lower is slightly trilobed, the palate is prominent. There are four stamens, two of which are frequently sterile. The capsule dehisces septicidally or loculicidally, and contains numerous small seeds. The genus is di-

vided into two sections: *Achetaria*, having two sterile stamens and septicidal dehiscence of the capsule; and *Dizygostemon*, with the four stamens fertile, and dehiscing loculicidally. In habit the species of this genus have very much the appearance of *Acanthaceae*. [W. G.]

**BHABHUR** or **BHABHUR**. An Indian name for the silky leaves of *Eriophorum cannabinum*, used for making cordage.

**BHADLEE**. *Panicum pilosum*, a broad-corn cultivated in India.

**BHANG**. An intoxicating drug obtained in the East from the Hemp, *Cannabis sativa*.

**BHEL**. The Indian name of the fruit of *Egle Marmelos*.

**BI**. In compound words=twice.

**BIACUMINATE**. Having two diverging points.

**BIARTICULATE**. Two-jointed.

**BIARUM**. One of the numerous new genera of *Araceae* proposed by Schott on comparatively slight grounds. This genus differs from *Arum* in its spathe being tubular at the base, with the limb spreading. The female flowers, moreover, have a distinct style, and the fruit contains only one ovule. The plants, which are much like the species of *Arum*, are natives of the south of Europe. [M. T. M.]

**BIARUTE**. Having two little ears. See also *Auriculata*.

**BIBACIER**. (Fr.) *Eriobotrya japonica*.

**BIBIRI**. The Greenheart Tree, or Bee-beercee of Guiana, *Nectandra Rodia*.

**BICALLOSE**. Having two callosities, as the lip of many orchids.

**BICARINATE**. Having two elevated ribs or keels on the under side, as in the pales of many grasses.

**BICEPS**. A term sometimes applied to the keel of a papilionaceous corolla when the ungues of the two petals of which it is composed are distinct.

**BICONJUGATE**. When each of two secondary petioles bears a pair of leaflets.

**BICONJUGATO-PINNATE**. When each of two secondary petioles is pinnate.

**BICORNELLA**. A genus of little known Madagascar Orchids nearly related to *Habermaria*. They have long almost leafless stems, terminated by a few orchis-like flowers.

**BICORNES**. A name originally given by Linnaeus to a group of genera, corresponding nearly to the heath family (*Ericaceae*) taken in its most extended sense. It has been lately revived by Klotzsch and others for the designation of a class to consist of *Vacciniaceae*, *Ericaceae*, *Epacridaceae*, and the smaller families or tribes included in or closely allied to them.

**BICORNIS, BICORNUTE**. Having two horn-like processes.

**BICORONA**. A genus of *Apocynaceae* remarkable, as the name implies, for having in the throat of the salver-shaped corolla, a double row of scales, each row consisting of ten, and the upper series being placed in pairs, before each lobe of the limb of the corolla, the lower row alternate with them. The five filaments are very short; the stigma is two-parted; and the fruit is like a berry. The only species is a shrub with erect branches, thick leaves, and flowers in axillary and terminal cymes, and is a native of New Caledonia. [M. T. M.]

**BICRURAL**. Having two legs or narrow elongations, as the lip of the man-orchis.

**BICUIBA**. *Myristica Bicuba*.

**BIDENS**. A somewhat extensive genus of herbaceous Compound flowers, growing both in the old and new world, well marked by the pericarp having, instead of a pappus, from two to five rigid awns which are rough with minute deflexed points. The British species of Bur-marigold, *B. cernua* and *B. tripartita*, are not unfrequent the borders of ponds and streams. They grow from one to two feet high, and may be distinguished while in flower by their button-like dingy-yellow flowers, which are surrounded at the base by an involucre of long bracts. The former has its flowers drooping; the latter has tripartite leaves. Neither of them is remarkable except for the tenacity with which the fruits cohere by their serrated awns to any penetrable substance to which they may happen to attach themselves. The foreign species possess little interest. French *Bident*; German *Zweyzahn*. [C. A. J.]

**BIDENTATE**. Having two teeth.

**BIDIGITATO-PINNATE**. Same as *Biconjugato-pinnate*.

**BIDUOUS**. Lasting two days only.

**BIDWILLIA**. A genus of Australian and Peruvian Liliaceous bulbs, with paniculate or racemose white flowers, only differing from the asphodels (*Asphodelus*) by having the filaments of the stamens thickened upwards. The leaves are linear, more or less glaucous; the roots fasciculate with knobbed ends. *B. glaucescens* is a native of the table-land called New England, in Australia. [J. T. S.]

**BIEBERSTEINIA**. This name commemorates the botanical services of Marschall von Bieberstein, a Russian naturalist. It is applied to a genus of *Rutaceae*, or, according to some authors, of *Zygophyllaceae*. The species are herbaceous plants, with pinnately divided leaves; flowers in terminal racemes, with five sepals and five petals; the stamens with filaments dilated at the base, between which and opposite to the petals are placed five round glands; ovaries five, distinct at the base and at the summit, but cohering in the middle, the five thread-shaped styles proceeding from

the inner side of the ovaries near their base, and uniting at the top into a single cup-shaped five-lobed stigma; fruits membranous, one-seeded. The species are natives of Persia, and the Altai and Himalayan mountains. [M. T. M.]

**BIENERIA.** A genus of terrestrial Orchids, proposed by the younger Reichenbach, but hardly distinct from *Chloraea*.

**BIENNIAL.** Requiring two years to form its flowers and fruit, and then dying: growing one year, and flowering, fruiting and dying the next.

**BIFARIOUS, BIFARIAM.** Arranged in two rows. This term is frequently applied to flowers and to ovules.

**BIFARIOUSLY IMBRICATED.** Overlapping in two rows.

**BIFEROUS.** Double bearing; producing flowers or fruit twice in the same season.

**BIFID.** Split half way down into two parts

**BIFLOROUS.** Bearing two flowers on the same footstalk. Also flowering twice in the same year.

**BIFOLIOLATE.** Having two leaflets only to a leaf.

**BIFOLLICULUS.** A double follicle.

**BIFORATE.** Having two pores or apertures.

**BIFORINES.** Oblong cells, with an aperture at each end, through which raphides are expelled.

**BIFRENARIA.** A name given to those *Maxillaria*-like plants which have two fræna or caudicles to their pollen masses instead of four. The species are all from the tropics of America.

**BIFRONS.** Growing on both surfaces of a leaf. Also appearing equally like two different things. A term seldom used.

**BIFURCATE.** Twice-forked; having two pairs of diverging horn-like arms.

**BIG.** The common Bere or four-rowed Barley, *Hordeum vulgare*.

**BIGAMEA.** A Ceylon plant generally considered as belonging to *Combretaceæ*, but referred by Planchon to a separate order, *Ancistrocladus*: from *Ancistrocladus*, which is equivalent to *Bigamea*. It is a shrubby-stemmed climber, whose main stem is short and terminated by a tuft of wedge-shaped leaves: from this fascicle springs a branch, which towards its apex bears short alternate patent branches with terminal tufts of lanceolate leaves. The flowers have five petals, five stamens, an inferior ovary, a pyramidal style with three stigmas; fruit a pear-shaped drupe covered by the five-parted calyx limb. [J. T. B.]

**BIGANDEILLE.** (Fr.) *Cerasus vulgaris*.

**BIGARADE.** The bitter or Seville Orange, *Citrus vulgaris*.

**BIGARADIER.** (Fr.) *Citrus vulgaris*.

**BIGARREAUTIER.** (Fr.) *Cerasus avium*.

**BIGEMINATE.** Same as Biconjugate.

**BIGEMINOUS.** \* In two pairs; as the placentæ of many plants.

**BIGENERS.** Mule plants obtained by crossing species of different genera. This kind of hybridism has been said to be impossible: Kôlreuter in particular adduced examples of failure in the attempt; but modern experiments seem to show the possibility of such a union.

**BIGLUMIS.** Consisting of two of the scales called, among grasses, glumes.

**BIGNONIACEÆ.** (*Bignoniads*; the *Trumpet-flower* family.) A natural order of Dicotyledonous or Exogenous plants belonging to the sub-class Corollifloræ of De Candolle, and to the Bignonial Alliance of Lindley, which includes also figworts, acanthads, and gesneriworts. The order contains trees or twining or climbing shrubby plants, with usually opposite compound leaves, and showy often trumpet-shaped flowers. Calyx divided or entire, sometimes in the form of a spathe; corolla usually irregular, four to five-lobed, and with a swollen portion below its mouth; stamens five, unequal, one generally, two occasionally, abortive. Ovary having two cavities, surrounded by an expansion at its base; ovules attached to the central part of the ovary. Fruit a two-valved often pod-like capsule, divided by a spurious expansion of the placenta; seeds generally numerous and winged; embryo without albumen, and having broad leafy cotyledons. The plants are found in the tropical regions of both hemispheres, but predominate in the eastern. They extend in America from Pennsylvania in the north, to Chili in the south. They do not occur wild in Europe. The plants produce abundance of showy finely-coloured flowers. Some yield dyes; others supply timber. Among them are medicinal agents used in chest affections, and for worms. There are 46 genera and 452 species described. Illustrative genera: *Bignonia*, *Calosanthus*, *Catalpa*, *Eccremocarpus*, *Jacaranda*, *Spatheodea*, *Tecoma*. [J. H. B.]

**BIGNONIA.** The order *Bignoniaceæ* takes its name from this genus, which was itself so called in honour of the Abbé Bignon, librarian to Louis XIV. The species of *Bignonia* are remarkable for the beauty of their flowers, and hence many are cultivated in this country. *B. caprea-lata*, one of the handsomest species, is a native of North America, but capable of being grown in warm places in this country as an ornamental climbing plant. The other species are for the most part natives of the warmer regions of the western hemisphere. The botanical characteristics of the genus are a bell-shaped calyx, slightly wavy at the margin; an irregular bell-shaped corolla; five stamens, two long and two short of which are fertile, and one sterile; stigma divided into two lamellæ;

capsule like a long pod, with the partition between its two compartments parallel with the valves or walls of the pod: the seeds arranged in two rows and provided with a membranous wing. The wood of some of the climbing species is arranged in four divisions, so as to present a cross-like appearance when cut. The leaves are pinnate or sometimes consist of only two opposite leaflets. The flowers are borne in panicles, and are of various colours, but always handsome-looking. The fruit of most species is either unknown, or but superficially described. [M T M]

The *Bignonias* are scandent tendrilled plants, frequently climbing to the tops of the highest trees, their flexible stems, twisted like ropes, sometimes passing from tree to tree, descending to the ground at intervals, taking fresh root, and again ascending other trees; in some of the Brazilian forests they are so numerous as to render them almost impassable.

*B. allacea*, the Garlic shrub, or *lame à l'ail* of the French, is a native of Guiana and the West Indies, and is so called in consequence of the powerful odour of garlic emitted by its bruised leaves and branches. It is a square-stemmed climber, with leaves composed of elliptical leathery leaflets, joined together in pairs; its flowers are large and white.

*B. Kereke* is a climbing shrub with smooth angular stems. Its leaflets are in pairs of three upon a single stalk, of an elliptical form, and rather hairy upon the under surface; the flowers are about two inches long, downy, and of a yellow colour. The natives of French Guiana, where this plant is indigenous, use the tough flexible stems as a substitute for ropes, and from strips of them they weave various kinds of baskets, and broad brimmed hats which protect them from both sun and rain.

*B. (?) Chica* is the most useful species of the genus. It is a native of Venezuela, New Grenada, and Guiana, and has long climbing stems, which reach to the tops of the trees, where they divide into numerous small branches which support themselves by means of their tendrils. Its leaves consist of eight leaflets arranged in pairs (conjugate), each pair having a tendril betwixt them, and possessing a separate stalk branching from the central leaf-stalk: the leaflets are oval. The funnel-shaped flowers are arranged in loose drooping panicles, and are of a violet colour: they produce a long flattened pod-like fruit, containing numerous winged seeds. A red pigment called Chica on the Orinoco, and Carajuru on the Rio Negro, is obtained by macerating the leaves of this plant in water, and is greatly used by the natives for painting their bodies, so much so that M. Humboldt, in speaking of the natives of the Orinoco, says:—"To form a just idea of the extravagance of the decoration of these naked Indians, I must observe, that a man of large stature gains with difficulty enough by the labour of a fortnight, to procure in exchange the chica necessary to paint himself red. Thus we say, in tempe-

rate climates, of a poor man, "he has not enough to clothe himself;" you hear the Indians of the Orinoco say, "that a man is so poor, that he has not enough to paint half his body." See ARRABIDJEA. [A. S.]

BIHAI. *Heliconia Bihai*.

BIJUGOUS. A pinnate leaf with two pairs of leaflets.

BIKH or BIKHMA. The poisonous root of *Aconitum ferox*.

BILABIATE. A corolla divided into two separate parts or lips, placed one over the other, as in Sage, Bugle, and similar plants.

BILAMELLATE. Consisting of two plates, as many placentae, stigmas, &c., or bearing two vertical plates, as the lip of some orchids.

BILBERRY. The fruit of *Vaccinium Myrtillus*, sometimes called Whortleberry, Whorts, or Hurts in country places.

BILIMBI TREE. *Averrhoa Bilimbi*.

BILLARDIERA. A genus of shrubs belonging to the *Pittosporaceae*, natives of Australia and Tasmania, with twining stems and alternate leaves; peduncles solitary from the apex of the branches, one-flowered, pendulous; calyx of five subulate sepals; petals five, combined into a tube below, generally yellow, occasionally blue or purple; stamens five; style thread-like, stigmas lobed; berry elliptical or cylindrical-ovoid, two-celled, many-seeded; pulp generally resinous. *B. mutabilis*, however, is said by Backhouse to have pleasant subacid fruit which at first is green, and at last amber-coloured. *B. longiflora* has pretty blue berries. [J. T. S.]

BILLBERGIA. A genus of *Bromeliaceae*, so called in honour of a Swedish botanist. It is characterised by a superior three-parted calyx; corolla of three convolute petals, scaly at the base; stamens inserted into the base of the perianth; style thread-shaped; stigmas linear convolute; fruit berry-like. The flowers are generally very elegant, bluish-red or yellow, borne on light panicles, the leaves are harsh and rigid. These plants are found growing on trees in tropical America, and being capable of living without contact with the earth, they are hung on balconies, &c., in South American gardens, where they are much prized for the beauty and fragrance of their flowers. Many species are cultivated for ornament in our stoves. A yellow dye is extracted from the root of *B. tinctoria* in Brazil. [M. T. M.]

BILOBED. Divided into two lobes.

BILSTED. An American name for *Liquidambar styraciflua*.

BINESTRAL. Existing for two months only.

BINUS. Lasting two years.

BINATE, BINUS. In pairs. Also the same as Bifoliate.

**BINATO-PINNATE.** The same as *Bipinnate*.

**BINDWEED.** The common name for *Convolvulus*, especially *C. arvensis*; also applied to *Smilax aspera*. —, **BLACK.** *Polygonum Convolvulus*.

**BINDWITH.** A name applied to *Clematis*.

**BINI.** Two together; twin.

**BINFLOUS.** Bearing flowers in pairs; a term seldom used.

**BINODAL.** Consisting of two nodes or articulations, and no more.

**BIOTA.** A generic name proposed for the *Thuja orientalis* and *T. pendula*, which differ from the *T. occidentalis* and other American species in not having wings to the seeds. The genus is not, however, generally adopted.

**BIOTIA.** Formerly considered as a distinct genus from that of the *Michaelmas Daisy* (*Aster*), but now united with it. The species are perennial herbs, one to three feet high, their root-leaves large, on long stalks, and heart-shaped in form, those of the stem, ovate or oblong and narrowed towards the base into a winged footstalk; their flower-heads arranged in terminal corymbs, and very like those of the *asters*. The species are found in Canada, and the United States, and one occurs in Manchuria. [A. A. B.]

**BIPALEOLATE.** Consisting of two small scales or palae, as in grasses.

**BIPARTITE.** Divided nearly to the base into two parts.

**BIPENTAPHYLLOUS.** Having from two to five leaflets.

**BIPES.** Same as *Bicuris*.

**BIPINNATE, BIPINNATISECTED.** When the primary and secondary divisions of a leaf are pinnated.

**BIPINNATIFID, BIPINNATIPARTED.** When both the primary and secondary segments of a leaf are pinnatifid.

**BIPINNATIPARTITO-LACINIATE.** Being bipinnatifid with the divisions lacinated.

**BIPINNULA.** A small genus of terrestrial orchids related to *Aethusa*, with fleshy fasciated roots, consisting of little except starch and gum. The flowers are large, racemose, greenish yellow, and most remarkable for having the lateral sepals broken up into tufts of exquisitely beautiful fringes. Two species occur in Chili, and one in the Argentine States, near Buenos Ayres.

**BIPPLICATE.** Having two folds or pluts.

**BIPOROSE.** Opening by two round holes.

**BIRADIATE.** Consisting of two or more rays, as in certain umbels.

**BIRCH.** The common name for *Betula* —, **WEST INDIAN.** *Bursera gummiifera*.

**BIRCH CAMPHOR.** A resinous substance obtained from the bark of the black Birch, *Betula nigra*.

**BIRCHWORTS.** A name given by Lindley to the Betulaceous order.

**BIRDLIME.** A preparation of the bark of the Holly, *Ilex Aquifolium*; also obtained from the viscid berries of the Mistletoe, *Viscum album*.

**BIRD-PLANT, MEXICAN.** *Heterotoma lobeliales*.

**BIRDS BILL.** *Trigonella ornithorhynchus*.

**BIRD'S-EYE.** *Veronica Chamaedrys*. —, **AMERICAN.** *Prunus pusilla*.

**BIRD'S FOOT.** The common name for *Ornithopus*, sometimes called Bird's-foot Vetch, also applied to *Lotus corniculatus*, and to *Euphorbia Ornithopus*.

**BIRD'S HEAD.** The common name for *Ornithocephalus*.

**BIRD'S-NEST.** *Neottia Nidus-avis*; also applied to *Thaunopteris* or *Asplenium Nidus*. —, **YELLOW.** *Monotropa Hypopitys*.

**BIRD'S-NEST PEZIZA.** The common name for the species of *Cyathus* and *Nidula* etc.

**BIRD'S TONGUE.** The common name for *Ornithoglossum*; also applied to *Senecio pulinosus*.

**BIRMOSE.** Opening by two slits, as in most anthers.

**BIRTHROOT.** An American name for *Trillium erectum*.

**BIRTHWORT.** The common name for *Aristolochia*.

**BISAILLE.** (Fr.) *Pisum arvense*.

**BISCUIT ROOTS.** A name given in Oregon to the tuberos roots of some umbelliferous plants allied to *Ferula*.

**BISCUTELLA.** A genus of herbs belonging to the *Cruciferae*, natives of central Europe, the Mediterranean region, and central Asia. Often hispid, with erect rigid stems, frequently corymbosely branched at the summit; leaves oblong, entire, or pinnatifid, very variable in this respect even within the limits of a single species; racemes short, elongated in fruit; flowers rather small, yellow; pouch flattened, with the partition narrow and the valves orbicular, flattened, and winged, breaking away from the axis when the seeds are ripe; seeds, one in each valve, and contained in it when it falls off. *B. laevigata* is a common subalpine plant of central Europe, &c., very variable in appearance, and remarkable for its curiously-shaped seed-vessels, which are notched both at the base and apex. Some of the species have them notched only at the base. [J. T. S.]

**BISEPTATE.** Having two partitions.

**BISERIAL.** Arranged in two rows not on opposite sides of an axis; as on a flat surface.

**DISERRATE.** When serratures are themselves serrate.

**BISH or BISHMA.** The poisonous root of *Aconitum ferox*.

**BISHOP'S CAP.** An American name for *Mitella*.

**BISHOPWEED.** *Egropodium Podagraria*; also applied to the *Sison Ammi* of Linnaeus; and as a common name to the genus *Ammi*. — **MOCK.** An American name for *Discochloa*.

**BISTORT.** *Polygon m Bistorta*.

**BITCHWOOD.** The timber of *Piscidia carthagenensis*; much esteemed in Jamaica for making the naves of wheels.

**BITERNATE.** When the principal divisions of a leaf are three, each of which bears three leaflets.

**BITTEN.** Terminated irregularly and abruptly; applied to leaves and roots.

**BITTER-BLAIN.** A name given by the Dutch Creoles in Guiana to *Pandanus diffusa*.

**BITTER KING.** *Soulaema amara*.

**BITTER-SWEET.** *Solanum Dulcamara*; also an American name for *Celastrus scandens*.

**BITTER WOOD.** *Xylopia glabra*; also used in gardens for the genus *Xylopia*.

**BITTERWORT.** An old name for *Gentiana lutea*.

**BIVITTATE.** Having two vittæ.

**BIXACEÆ, BIXINÆ.** A name sometimes given to the order of bixads, more generally called **FLACOURTIACEÆ** (which see).

**BIXA.** A name applied by the Indians of Darien to the plant producing the Arnotta of commerce, and adopted by botanists for the genus of *Flacourtiaceæ*, to which it belongs. There are four species known, all of them natives of tropical America, and forming small trees, with entire leaves marked with numerous pellucid dots. Their flowers are produced in large bunches at the ends of the young branches; and have a calyx consisting of five sepals, which alternate with five wart-like swellings on the stalk, and likewise with the five petals; numerous long free stamens, and a long style terminating in a two-lobed stigma. Their fruit has a dry prickly husk, which splits into two pieces, each bearing numerous seeds attached in a perpendicular row on their inside.

*B. Orellana* is a small tree growing about twenty or thirty feet high, having broad heart-shaped pointed leaves, and bunches of rose-coloured flowers. Its fruit is heart-shaped, rather more than an inch long, of a reddish-brown colour, and

covered with stiff prickles. The seeds have a thin coating of red waxy pulp, which forms the substance called Arnotta; it is separated by throwing the freshly-gathered seeds into a tub of water, and stirring them until the red matter is detached, when it is strained off and evaporated to the consistency of putty.

*Bixa Orellana.*

in this state it is made up into rolls and wrapped in leaves, and is then known as sag or roll arnotta; but when more thoroughly dried, it is made into cakes and called cake arnotta. In South America arnotta is greatly used by the Caribs and other tribes of Indians for painting their bodies: paint being almost their only article of clothing. In this country it is used for colouring cheese, inferior chocolates, &c.; and by the Dutch for colouring butter. It is also used by silk-dyers; and by varnish-makers for imparting a rich orange tint to some kinds of varnish. [A. S.]

**BLACKBERRY.** The Bramble, *Rubus fruticosus*, and its numerous varieties.

**BLACKBURNIA.** A genus of *Xanthoxylaceæ*, consisting of trees with alternate pinnate leaves, and flowers in panicles. The parts of the flower arranged in fours; ovary solitary, on a short stalk, one-celled, one-seeded, with a short style and simple stigma; capsule tough, partly two-valved. These trees, inhabiting Norfolk Island and the East Indies, resemble the species of *Ptelea*, but are known by their simple stigma and wingless fruit. *B. pinnata* is occasionally cultivated. [M. T. M.]

**BLACK DRINK.** A decoction of *Ilex vomitoria* used by the Creek Indians.

**BLACK JACK.** An American name for *Quercus nigra*.

**BLACK NONESUCH.** *Medicago lupulina*.

**BLACKTHORN.** *Prunus spinosa*.

**BLACKWELLIA.** A genus of *Homalidae*, named in honour of Elizabeth Blackwell, the author of a forgotten herbal; technically it is characterised by having an adherent top-shaped calyx, whose limb is divided into from five to fifteen divisions, glandular at the base or in the centre; stamens opposite the petals; ovary conical above, with three to five styles; fruits a one-celled many-seeded capsule. The species are small trees, natives of India, Mauritius, and China. *B. padiflor.* greenhouse shrub, much resembles the common *Prunus Padus* in appearance; and there are also other species of the genus in cultivation. [M. T. M.]

**BLACK WOOD.** An Indian furniture wood obtained from *Dalbergia latifolia*; also a name for that of *Melantheria Melanoxylon*. — of New South Wales. *Acacia Melanoxylon*.

**BLADDER-GREEN.** A colour obtained from the berries of *Rhamnus catharticus*.

**BLADDER KETMIA.** *Hibiscus Trionum*.

**BLADDER-POD.** The common name for *Physolobium*.

**BLADDER-SEED.** The common name for *Physospermum*.

**BLADDERWORT.** The common name for *Utricularia*.

**BLADDERY.** Inflated like an animal bladder; as the fruit of the Bladder Senna, *Colutea arborescens*.

**BLADE.** The lamina or expanded part of a leaf.

**BLADDERIA.** A genus of *Ericaceae*, containing many heath-like shrubs, from the Cape of Good Hope, with opposite and ternate leaves, and terminal clusters of flowers. The calyx is four-parted; the persistent corolla is campanulate, sometimes a little expanded below. The four stamens are inserted below the hypogynous disc. The ovary is four-celled, with many ovules in each cell. The capsule is globular with four rounded angles. The habit and structure of the members of this genus are the same as in *Erica*, from which they differ only in having four instead of eight stamens. [W. C.]

**BLAKEA.** A genus of trees or shrubs belonging to *Melastomaceae*, natives of tropical America, with opposite petiolate three or five-nerved leathery leaves, glabrous and shining above, often covered with short rust-coloured wool beneath as well as the peduncles, which are axillary and

**BLANC D'EAU.** (Fr.) *Nymphaea alba*. — DE HOLLANDE. *Populus alba*.

**BLANCHETTE.** (Fr.) *Valeriana Locusta*.

**BLANCHING.** A whitening of the usually green parts of plants, to which the term Albefactio is applied.

**BLANCOA.** A genus of *Hæmodoraceae* plants, consisting of dwarf stemless herbs, with the aspect of a *Barbacenia*, having equitant hoary falcate acuminate leaves as long as the furfuraceous scape, which latter supports two or three large nodding flowers, both flowers and peduncles being clothed on the outside with plumose hairs. The perianth is elongately bell-shaped or sub-clavate, with an erect six-toothed equal limb, and is furnished with six sub-sessile anthers. The species *B. canescens* is found in the Swan River Colony. [T. M.]

**BLANDFORDIA.** A genus of *Liliaceae*, consisting of very handsome perennial herbs, having linear elongate striate radical leaves, dilated and somewhat sheathing at the base; others shorter and more distant, appearing on the flower-stem, which is simple with a many-flowered raceme at the top. The flowers are solitary on recurved pedicels, and have a tube funnel-shaped six-cleft regular perianth, with ovate acutish segments, six equal stamens, scarcely exerted, and a free long-stalked narrow three-celled ovary, terminated by a filiform style and obtuse stigma. Several species, natives of New Holland and Tasmania, are known. *B. marginata* has rigid sub-erect leaves, scabrous along the margin, and lengthened racemes of pendulous, conically funnel-shaped flowers, which are of a deep rich coppery red outside, yellow within and at the edges of the round petaline divisions, which at the back terminate in a sharp orange-coloured point. In *B. nobilis* the leaves are very narrow and entire, and the flowers are ventricosely funnel-shaped, subumbellate, red with the upper half yellow. *B. grandiflora* has rigid erect leaves serrated at the point and short racemes of pendulous ventricosely funnel-shaped flowers, which are red with the upper half yellow, and have retuse petals. In *B. Cunninghamii* the leaves are weakish, spreading, quite entire and smooth; the flowers pendulous, conical, inflated at the apex, subumbellate, reddish throughout, the segments all acute, and the stamens somewhat exerted. They are all handsome plants, and some one or other of them may not unfrequently be met with in our greenhouses. [T. M.]

**BLASTEMA.** The axis of an embryo, the radicle and plumule, and the portion; also the

thallus of a lichen.

**BLASTHEMANTHUS.** A tree found near the Amazon river, has been considered by Planchon to belong to a new genus of *Octonaceae*, to which he gives the above name. Its botanical characters are interesting; the chief are: a double calyx, each of five over-

[J. T. S.]

lapping pieces: five petals; twenty glands in one row, exterior to the ten stamens; anthers prolonged into a leaf-like process, opening by two pores, the stamens after flowering turned to one side of the flower; ovary placed on a very short stalk, three to five-celled, and many-seeded. The alternate oblong leaves have cartilaginous stipules inserted on to the branch above the insertion of the leaf. [M. T. M.]

**BLASTIDIA.** Secondary cells generated in the interior of another cell.

**BLASTUS.** The plumule.

**BLAZE', or BLANZE.** (Fr.) A species of *Triticum*.

**BLAZING STAR.** A North American name for *Liatris squarrosa*, and *Chamaelirium luteum*.

**BLE'**. (Fr.) *Triticum vulgare*. — **BARBU.** *Triticum turgidum*. — **D'ABONDANCE.** *Triticum compositum*. — **DE BARBAIRE.** *Polygonum Fagopyrum*. — **DE MIRACLE.** *Triticum compositum*. — **DE TURQUIE.** *Zea Mays*. — **DE VACHE.** *Melampyrum arvense*. — **NOIR.** *Polygonum Fagopyrum*. — **TURC.** *Triticum compositum*.

**BLEABERRY.** The Bilberry, *Vaccinium Myrtillus*; sometimes also applied to the Bog Whortleberry, *Vaccinium uliginosum*.

**BLECHNIDIUM.** A genus of polypodiaceous Ferns, closely related to *Blechnum*, from which it differs only in the veins being reticulated instead of free. The only species, *B. melanopus*, is a native of India, and is a moderate-sized pinnatifid fern, with falcate segments, having a general resemblance to the common garden *Blechnum occidentale*. As its trivial name indicates, the stipes or stalk of the frond is black. [T. M.]

**BLECHNOPSIS.** A name proposed by Presl for certain species separated from *Blechnum*, namely, *B. orientale*, *cartilagineum*, *brasiliense*, &c. It is not adopted by other pteridologists. [T. M.]

**BLECHNUM.** A considerable genus of polypodiaceous Ferns belonging to the group *Lomariaceae*. They are plants with simple pinnatifid or pinnate fronds, of which the fertile ones are sometimes more or less contracted. They are distinguished by having the sori linear, lying parallel with and more or less approximate to the midrib, and therefore theoretically distant from the margin, but sometimes becoming at the same time sub-marginal by the contraction of the fronds. These sori are covered by linear indusia, which are attached along that side of the receptacle which is nearest the margin of the frond, and open along the inward side, or that which is nearest to the midrib. The veins, as seen in the sterile fronds, where they are uninterrupted by the development of the fructification, are free, that is, they branch out from the costa, and become forked as they extend towards the margin,

without coming in contact with each other; but in the fertile fronds they are combined within the margin, and generally near the base by the receptacle which runs transversely to them. Leaving out of view *Blechnum*, which is distinguished from *Blechnum* only by the reticulation of its veins, its nearest ally is *Lomaria*, which indeed presents sometimes so little difference that the same plants are in some cases indifferently referred to either genus by different authors, or even by the same author in different publications. The proper distinction between the two consists in the fructification of *Lomaria* being marginal, and that of *Blechnum* within the margin, and this irrespective of the contraction of the fronds, which latter feature has sometimes been taken as the mark of *Lomaria*.

The species of *Blechnum* range under two divisions, in one of which, represented by the Indian *B. orientale*, the sori are placed very near the costa, and in the other, represented by our native *B. Spicant*, it becomes sub-marginal from the contraction of the fronds. The former group is the more typical. *B. orientale* is a tall-growing and very handsome fern found throughout India and the East. It has a short caudex, which is clothed with long narrow glossy scales. The fronds, which are often three feet long or more, are pinnate, the pinnae sometimes a foot long, elongately linear, tapering to a narrow point. *B. Spicant* is a humbler plant, producing horizontal pectinately pinnatifid sterile fronds, and erect fertile ones, with narrower or contracted segments. The genus contains a considerable number of species, which are abundant in tropical countries, a large proportion of them being found in the northern parts of South America, in the West Indian Islands, in India, and in the various islands of the Eastern sea. A few species occur in Australasia, at the Cape of Good Hope, and in Chili; and our native, *B. Spicant*, is found throughout Europe, in Madeira and the adjacent islands, in the Caucasian regions, and in Kamtschatka. [T. M.]

**BLECHUM.** A genus of herbaceous plants of the order *Acanthaceae*, abundant in tropical America, and occurring also in India and Madagascar. The flowers are in large axillary or terminal spikes; they spring from the axils of broad herbaceous imbricated bracts. The calyx is deeply five-cleft; the corolla is funnel-shaped, with a long tube and a small regular five-lobed limb; the four included didynamous stamens are inserted in the middle of the tube; the anthers consist of two oval parallel cells; the ovary is two-celled, with four or more ovules in each cell; the style is simple, and the stigma bifid. The ovate capsule is two-celled, with eight or more roundish seeds. [W. G.]

**BLEEKERIA.** This name has been applied to a tree, native of New Holland, and the island of Ceram, in honour of Dr. Bleeker, a distinguished student of the

natural history of India, especially of the fishes of that country. The genus is one of the apocynaceous family, characterised by a calyx without glands, a salver-shaped corolla with a slightly distended tube, and no scales at its throat. Filaments adherent to the tube of the corolla for some distance, hairy; anthers linear, slender, with the connective prolonged for a short distance beyond the lobes. Ovaries two, small, roundish, each containing two ovules, placed one over the other; style short; stigma almost globular below, tapering above and hairy, slightly two-lobed at the point. Fruit of two fleshy purple drupes, or one by abortion, with a hard woody inner shell. [M. T. M.]

**BLENNOSPORA.** *B. Drummondii* is the name given to a little West Australian plant which belongs to the cudweed section of the composite family. It is seldom taller than three inches, and is altogether covered with loose woolly hairs. Its leaves are alternate, and linear in form. The flower heads, of a brown colour, are arranged in dense terminal clusters, each of the heads containing but two florets. The generic name refers to the cellular coating of the achene becoming gelatinous when moistened. [A. A. B.]

**BLEPHARÆ.** The teeth or fringes belonging to the peristome of an urn-moss.

**BLEPHARIS.** A genus of *Acanthaceæ*, natives of Asia and Africa. They are creeping herbaceous plants, with verticillate unequal leaves, and axillary spikes in which the lower bracts are sterile and closely imbricated, while the two terminal bracteoles contain a single flower. The calyx is four-parted, of which the upper and lower divisions are broadest, and the lower bidentate. The corolla is one-lipped, its anterior portion being trifid, and the posterior tridentate. The four stamens are sub-dynamous, the anthers on the longer pair of filaments one-celled, while the shorter filaments bear two-celled anthers. The two-celled ovary has two ovules in each cell; but the carpellary fruit contains sometimes only two seeds, from the abortion of two of the ovules. [W. C.]

**BLEPHAROCHLAMYS.** A name synonymous with *MYSTROPETALON* (which see). [M. T. M.]

**BLEPHILIA.** A genus of the mint family, *Labiata*, peculiar to the United States, and nearly related to horse-mints (*Monarda*), but the calyx tube has thirteen instead of fifteen nerves, and is naked in the throat, while the throat of the corolla, which are much smaller than in *Monarda*, are more markedly dilated. There are two species, *B. hirsuta* and *B. ciliata*, the former with long stalks to the leaves, the latter with nearly sessile leaves; and both with the habit, appearance, and odour of our own mints (*Mentha*). The purplish flowers are disposed in axillary or terminal globular whorls, surrounded with coloured

bracteas, which, like the calyx-teeth, are fringed with hairs. To this fringe the generic name, derived from the Greek, signifying eyelash, refers. [A. A. B.]

**BLETIA.** A large genus of terrestrial orchids chiefly from tropical America, where they inhabit swampy places. They have narrow grass-like leaves, and purple or whitish flowers in long terminal racemes, in almost all cases handsome enough to claim the notice of gardeners. Very few species occur in the Old World, among which is *B. hyacinthina*, cultivated in China for the sake of its fragrance. In their manner of growth they are much like *Cymbidiums*.

**BLETTING.** That kind of change in tissue which results in the formation of a brown colour, without putrefaction, as in the fruit of the medlar. The term *Hypsothia* is applied to this change.

**BLEWITS.** The popular name in some parts of England for *Agaricus personatus*, a species which is frequent in rich meadows in autumn, and is known by its pale bluish-coloured or purplish convex fleshy pileus, pallid gills, and thick stem, tinged more or less with violet. It is sometimes exposed for sale, but is a fungus of inferior quality for the table. It is in general believed to be wholesome; but in a case of poisoning from the use of fungi at Cambridge, some years since, the principal part of the stew consisted of this species. Dr. Bachman, however, speaks highly of it, when not sodden with water, and suggests that the name is a corruption of Blue Hats. [M. J. B.]

**BLIGHIA.** A genus of *Sapindaceæ*, named in honour of Captain William Bligh, of H.M.S. *Bounty*, who, in the year 1787, was appointed to convey the bread-fruit and other trees from Tahiti to the West Indies. It consists of only one species, *B. sapida*, which produces the Akee fruit. This plant is a native of Guinea; but it has been introduced into and is now common in the West Indies and South America. It forms a small tree about thirty feet in height, having compound leaves consisting of three or four pairs of broadly lance-shaped downy leaflets. Its flowers are produced in racemes from the axils of the leaves. They have a calyx consisting of five pieces; five white petals bearing a large two-lobed scale near the base on their inside; eight stamens; and a short style bearing three stigmas. The fruit is fleshy, and of a red colour tinged with yellow, about three inches long by two in width, and of a three-sided form; when ripe it splits open down the middle of each side, disclosing three shining jet-black seeds, seated upon and partly immersed in a white spongy substance called the aril. This aril is the eatable part of the fruit, and in tropical countries, where it comes to perfection, it is said to possess an agreeable sub-acid taste, very grateful to the palate; but fruits ripened in the hothouses of this country have not been found to possess such good qualities, their

pound compressed spikes; spikelets with two to eight flowers, which are all hermaphrodite; stamens three; styles cleft. Four species are described, two of which are natives of Britain, namely, *B. rufus* and *B. compressus*. The former occurs frequently in salt-marshes, near the sea-coasts of England and Ireland; but the latter is rather rare, particularly in Ireland. *B. brevifolius* is a native of India. [D. M.]

**BLYTTIA.** A genus of Grasses belonging to the tribe *Agrostideæ*. Only one species is described, *B. suaveolens*, which is the *Cinna pendula* of Steudel's *Synopsis*, and a native of Norway. [D. M.]

**BLYXA.** A small genus of stemless aquatic plants found in India and Madagascar, belonging to *Hydrocharitaceæ* and allied to *Vallisneria*. They have linear leaves, which as well as the flowers are submerged. The flowers are dioecious, produced from a tubular spathe split at the end, which has several stalked flowers in the male plant, but only a single sessile one in the female; the perianth has three calyx-like outer segments, and three linear oblong petaloid inner ones, but in the female flower these are at the top of a long tube, adhering to the inferior ovary at the base, stamens three to eight; berry one-celled, as in *Vallisneria*. [J. T. S.]

**BOATLIP.** The common name for *Scaphyllis*.

**BOAT-SHAPED.** Having the figure of a boat in miniature, with its keel.

**BOBIA.** A genus which was for a long time known only from a short and imperfect description, and was generally placed in the *Combretum* family, but is now generally allowed to be a species of *Symplocos* (*S. spicata*). It is a small tree, all its parts of a yellowish-green colour, and retaining that colour in a dried state. The leaves are alternate, stalked and oblong; the flowers small, white or yellowish-coloured, and borne on short axillary spikes. The fruits are hard, small, and in form like a miniature pitcher, and are sometimes seen strung like beads, and used as necklaces by native children. The plant is common in India and Ceylon. [A. A. B.]

**BOCAGEA.** One of the genera of *Aucaceæ*, characterised by the calyx, which is either divided, of three segments, or entire and cup-shaped; the petals are six in number, distinct; the stamens definite in number, opposite to the petals. Ovaries three, one-celled, and containing five to eight ovules; styles free or none. Fruit berry-like, of from one to three carpels, which are on short stalks and contain only three seeds; the remainder being arrested in their growth; the seeds are horizontal and provided with an arillus. The species are trees inhabiting Brazil. [M. T. M.]

**BOCCONIA.** An interesting genus of *Papaveraceæ*, so named in honour of a Sicilian botanist. The calyx consists of two cream-coloured or pinkish sepals;

corolla none; stamens eight to twenty-four; style bifid; capsule not jointed, but two-valved, and containing from one to four seeds. The species have their flowers in graceful clusters, and the foliage is also elegant. *B. frutescens* and *B. integrifolia*, natives of the West Indies and Mexico, are in cultivation. *B. cordata*, a hardy species, is a native of China. [M. T. M.]

**BECKHIA.** A genus containing a few sedge-like plants from the Cape of Good Hope, belonging to the natural order *Restiaceæ*. The rhizome is creeping, throwing up slender simple rigid stems with small membranous sheaths. The flowers are unisexual with six small glumes, and are arranged in pairs or in terminal spikes. The male flowers have three stamens; the female a two-celled ovary with one ovule in each cell, and two plumose stigmas; fruit a hard nut containing one seed. [J. T. S.]

**BEENINGHATSENIA.** A genus of *Rutaceæ*, nearly allied to *Ruta* itself, but distinguished by its flat entire oblong petals; the ovaries also are placed on a thread-like column or stalk, which projects from a short cup-shaped disc. The species are natives of the East Indies. [M. T. M.]

**BOERHAAVIA.** This genus of *Nyctaginaceæ* commemorates a famous Dutch physician and naturalist, a contemporary and patron of Linnæus. The plants are herbs, widely distributed over the tropical and warmer regions of the globe. The flowers have no involucre; their perianth is in two divisions, the lower portion cylindrical, black, persistent, the upper funnel or bell-shaped, coloured, deciduous, five-lobed at the top; stamens one to three, more rarely four, arising from a ring placed beneath the ovary. Ovary very small at the base of the perianth. Fruit within the enlarged hardened base of the perianth, frequently five-ribbed. The root of *B. procumbens*, a troublesome weed in India, is given as a laxative and vermifuge. Others are used as emetics, and for other medicinal purposes. Several species are in cultivation, but have no particular beauty to recommend them. [M. T. M.]

**BÖHMERIA.** This genus of the order of Nettles (*Urticaceæ*) contains numerous species distributed throughout the tropics and subtropics of both hemispheres. They are herbaceous plants or shrubs, closely allied to true nettles (*Urtica*), but differing from them in not having stinging hairs. The male and female flowers are produced in separate spikes on the same plant: the males having a four-parted calyx and four stamens, the females a tubular calyx divided into four teeth at the top, and a slender style with hairs along one side. Several of the species yield valuable fibres. The most interesting of them is *B. nivea*, the Tehou-ma of the Chinese, the Rheon of Assam, and the Chinese Grass-cloth plant of English writers. It is a small shrubby plant about three or four feet

high, throwing up numerous straight shoots, which are about as thick as the little finger and covered with short soft hairs. Its leaves grow upon long hairy footstalks, and are broadly heart-shaped, about six inches long by four broad, terminating in a long slender point, and

*Böhmeria nivea.*

having their edges cut like a saw. They are of a deep green colour on the upper side, but covered on the under side with a dense coating of white down, which gives them an appearance, like that of frosted silver. The beautiful fabric known in England as Grass-cloth, and rivaling the best French cambric in softness and fineness of texture, is manufactured from the fibre obtained from the inner bark of this shrub, which is a native of China and Sumatra, and has long been cultivated in those countries and also in India, where it has recently been recognised as identical with the *Rheea* of Assam. The Chinese bestow much care and labour upon its cultivation and the preparation of its fibre, called Rammie fibre, they obtain three crops of the stems annually, the second being considered the best. To obtain the fibre the bark is stripped off in two long pieces and carefully scraped with a knife, so as to get rid of all useless matter, after which it is softened and separated into fine filaments, either by steeping it in hot water or holding it over steam. The fibre is of different degrees of fineness according to the age of the plant, and the part of the bark from which it is taken: the inner bark of young quickly grown stems yielding the beautifully fine delicate fibre from which the best fabrics are manufactured, while the outer portion affords a coarse fibre only fit for making ropes, canvass, &c. Experiments made with the view of testing the strength of this fibre have proved it to possess nearly double the tenacity of Russian hemp.

*B. Puya*, which is a native of Nepal, very

closely resembles the preceding both in its botanical characters and general appearance. It is, however, rather taller, growing as high as six or eight feet, and its leaves are of a different form, being broadly lance-shaped, and terminating in a sharp point; but they have serrated edges, and are silvery on the under side as in the last. This plant is called Poonh or Puya in Sikkim and Nepal, and its fibre has long been in use among the natives; but they have hitherto employed clay or mud in its preparation, which greatly deteriorates its value. When properly prepared it is very strong, and makes good cordage and sail-cloth. Of the other species of this genus we may mention that the inner bark of *B. albida* is used in the Sandwich Islands for making cloth; and *B. caudata* is employed medicinally in Brazil. [A. 8.]

BOIS A' BALAIS. (Fr.) *Betula alba*. — A. LARDOIRE. *Eucornutus europæus*. — BOUTON. *Cephalanthus occidentalis*. — CUIL. *Droca palustris*. — D'ARC. *Maclura aurantiaca*. — DE CHINE. *Murraya exotica*. — DE CHYPRE. *Cordia Gerascanthus*. — DE COCHON. *Hedysium balsamifera*. — DE COLOPHANE. *Bursera paniculata*. — D'HUILE. *Erythroxylon hypericifolium*. — DE LETTRES. *Brassica subulata*. — DE LOUSTAU. *Antirrhoea verticillata*. — DE MAI. *Crataegus oxyacantha*. — DE PALIXANDRE. The Rosewood of cabinet-makers obtained from different species of *Dalbergia*, as *D. latifolia*, and *D. nigra*. — DE PERDRIX. *Hesperia coccinea*. — DE SAINTE LUCIE. *Prunus Mahaleb*. — DE ROSE. *Lucaria guianensis*. — GENTIL or JOLI. *Daphne Mezereum*. — ROUGE. *Gumma grandifolia*. — TAN. *Byrronima spicata*.

BOISDEVALIA. A small genus of North American Onagraceæ, separated by Spach from *Oenothera*, from which it differs chiefly in the four stamens, which are opposite the petals, being shorter than the alternate ones, and in the rosy or pinkish colour of the corolla; the flowers of the true *Oenotheras* being either white or yellow. Only two species are known. *B. densiflora* and *B. concinna*, both of annual duration. The former is an erect woolly slightly-branched plant, with linear lanceolate pointed toothed leaves, and is remarkable for having the axillary buds of the main stem, which usually produce but a single flower, developed into a short branch bearing a small corymb of flowers; it has little beauty to recommend it. *B. concinna* is of trailing habit, with small ovate-lanceolate leaves and pretty pink flowers in terminal leafy spikes. [W. T.]

BOISSIELLE. (Fr.) *Bossiaea Scolopendra*.

BOJERIA. A genus of one species (*B. speciosa*) belonging to the composite family, and found in Madagascar. It is a shrub about ten feet high, the stems towards the apex covered with dense rusty hairs. The leaves are alternate, entire, ovate or lanceolate in form, and

clasping the stem by their base, nearly smooth above, and densely tomentose beneath. The flower-heads are single from the apex of the branches, and about one inch in diameter, having numerous purple tubular florets, all of them containing both stamens and pistil. The genus bears the name of M. Bojer, Professor of Botany in the Mauritius. [A. A. B.]

**BOLBITIS.** A name proposed for certain acrostichaceous Ferns, now referred to *Pecopteris*. [T. M.]

**BOLBOPHYLLUM.** A very extensive genus of Orchids of small stature growing on trees or overrunning the ground among mosses. Their leaves are usually solitary on fleshy pseudobulbs; and their flowers are small and inconspicuous, in racemes or small capitules. Some, however, have fleshy deeply-coloured flowers in dense spikes. In structure they differ little from Dendrobies except that the column is terminated by two conspicuous lateral bristles or teeth. Nearly one hundred species are known from the tropics of the Old and New Worlds. The focus of the genus is Africa and Asia.

**BOLDOA.** The name given to a small Chilean tree belonging to the *Momima* family. It has opposite short-stalked ovate leaves, which are entire and rough on the surface. The flowers in little axillary racemes, the males and females on different plants. The centre of the male flower is occupied by a great many stamens, and that of the female by from two to nine ovaries, which when ripe are succulent drupes, about the size of haws, and very aromatic, as are all the parts of the plant. The bark is serviceable to tanners, and the wood is preferred before any other in the country for making charcoal; while the fruits are eaten. The tree is known in Chili as Boldu. [A. A. B.]

**BOLDU.** A genus of *Lauraceæ*, consisting of Chilean shrubs, with hermaphrodite flowers in axillary panicles. The calyx is six-cleft, rotate, with persistent thick segments; the three inner stamens have on either side at their base a sessile gland; the anthers are two-celled. Boldu is besides the Chilean name for *Boldoa fragrans*. [M. T. M.]

**BOLET DU MÊLEZE (Fr.)** *Polyporus gnomoides*.

**BOLETS.** (Fr.) *Boletus*.

**BOLETUS.** A genus of hymenomycetous Fungi, distinguished by the hymenium consisting of tubes separable from each other, as well as from the pileus or cap. In a few instances the tubes are separable from the pileus in the more fleshy *Polyporus*, but never so completely from each other as in this genus. All the species have a strong stem, and in a few this is furnished with a ring. They are numerous and often difficult of determination. Some of them are highly poisonous, while *B. edulis* is considered by

most people an excellent article of food. It is not much used in this country, but in Hungary it is preferred to the mushroom, which is regarded generally with suspicion. The most poisonous species are easily recognised by the red orifice of the tubes; but with the exception just mentioned there are not more than one or two acceptable species. One of the most curious points about these fungi is, that in several species the flesh from white or yellow turns instantaneously to blue when divided. It is believed that this arises from the action of ozone on the juice. Sir W. C. Trevelyan assures us that he eats even *B. luridus* with impunity. The late Mr Sauter, when employed on the Geological Survey, lived for some days almost exclusively on Boleti, which he gathered indiscriminately. *B. edulis* has sometimes been cultivated artificially in its native woods. [M. J. B.]

**BOLIVARIA.** A genus of the *Jasminæ* family confined to South Brazil and Chili. They are small woody plants from one to two feet high, with opposite entire or three-lobed leaves, and axillary or terminal yellow flowers, not unlike those of the *Jasminæ*, but smaller. The fruit is a two-lobed cartilaginous capsule, the upper part of which falls off in the form of a cap when the seeds are ripe. The genus bears the name of Bolivar, the celebrated liberator of South America; it is now united with *MENODORA*: which see. [A. A. B.]

**BOLTONIA.** A genus of three species, belonging to the Composite family, and peculiar to North America, where they extend from Canada southwards to the Southern states. They are smooth much-branched perennial herbs, with lanceolate pale green sessile leaves, and an abundance of flower-heads with white or purplish rays, very much like *Michaelmas daisies* (*Aster*), to which genus they might at a first glance be referred; but they differ in the pappus of the ray and disc florets being dissimilar, and consisting of numerous minute bristles, often with two to four longer awns also. The genus is dedicated to J. Bolton, an English botanist. [A. A. B.]

**BOMAREA.** A genus of amaryllidaceous plants closely related to *Aistrœria*, from which it is principally distinguished by its twining habit, and some differences in the capsule or fruit, which in *Aistrœria* is valvate, splitting from the base into three parts, and in *Bomarea* is coriaceous, and almost valveless, dehiscing from the upper end or apex. The species are rather numerous, and are all South American, found principally on the Peruvian Andes, a few being also met with in Mexico, Quito, and Chili, the greater part of them inhabiting elevated situations. *B. Aekilia* (the *oculata* of *Botanical Magazine*, t. 3344) is a very pretty twining plant, with smooth leaves, and umbels of purple flowers half an inch long, having a dark eye-like spot at the base of the two upper segments of the nearly equal perianth, and a pale one on the lowest. This spotting appears to have given rise to the name *oculata*.

*B. edulis* (the *Saleella* of *Bot. Mag.*, t. 1613), a West Indian species, produces tubers which are eaten in St. Domingo like those of the Jerusalem artichoke are in this country. [T. M.]

**BOMBACEÆ.** The Silk-cotton family, a group of Thalamifloral Dicotyledons or Exogens belonging to Lindley's Malval alliance, and usually considered as a sub-order of *STERCULIACEÆ*. [J. H. B.]

**BOMBAX.** Derived from the Greek word *bombyx*, signifying raw silk, and applied to a genus of large soft-wooded trees belonging to the order of Sterculiads (*Sterculiaceæ*), the fruits of which contain a beautiful silky substance attached to their seeds, and to which the name of Silk-cotton has been appropriately given. There are about a dozen species, almost entirely confined to the tropical regions of America, one species only being a native of Western Africa. Several Indian species, however, were formerly included in the genus, but they are now separated under the name of *Radmalia*; and the West Indian tree, commonly called *B. Ceiba* or God-tree, is the same as *Eriodendron anfractuosum*. Their flowers are produced either singly or in clusters upon the trunk or old branches, and are generally large and of a white or greenish colour: they have a short calyx shaped like the cup of an acorn, and a corolla of five pieces joined together at the bottom; their stamens are arranged in five or more bundles, which are connected together at the base into a short cylindrical tube, the filaments being divided into two branches near the top, each bearing an anther; and they have a shield-like stigma with five angles and furrowed sides. Their fruit is a large woody capsule, containing numerous seeds arranged in five cells, each seed being surrounded by a quantity of beautiful silky hairs, and when ripe it bursts into five pieces, allowing the escape of the seeds, which are then wafted about by the wind.

*B. Munguba* is a smooth-stemmed tree about eighty or one hundred feet high, commonly found on the banks of the Amazon river and the Rio Negro, where the natives call it Munguba. It has large smooth leaves deeply cut into eight divisions radiating from a centre, and large white or greenish flowers arranged in twos or threes on the branches. Its fruit is about eight inches long by four wide, and of a clear brick-red colour. The silk-cotton surrounding its seeds is of a light brown colour, and, although exceedingly beautiful, it has not hitherto been employed for any purpose more important than stuffing cushions; but it is to be hoped that a better use will some day be found for it.

*B. pubescens* is called Embirassu in the province of Minas Geraes, in Brazil. This species does not attain the great height of the preceding, being generally only about twenty-five or thirty feet high. It has a

smooth trunk covered with a very tough fibrous bark, which the Brazilians use for making ropes. The leaves are variable in shape; those on the lower part of the branches being hand-shaped, that is, cut into five radiating divisions, whilst those higher up on the branches have only three divisions: they are of a leathery texture and covered on the under side with star-like hairs. The large flowers are clothed with white silky down. [A. S.]

**BOMBYCINE.** Silky, feeling like silk: this term is not applied to hairiness of any sort.

**BONA-NOX.** *Ipomœa Bona-nox*; *Argyrea* or *Rivea Bona-nox*; *Smilax Bona-nox*.

**BONAPARTEA.** A genus of *Bromeliaceæ*, named in honour of Napoleon I., and consisting of plants with tufted narrow rigid leaves, which are convolute at the base; hermaphrodite flowers protected by bracts, and arranged on a simple or cone-like or branched scape; sepals spirally twisted, either all equal in size, or the two hinder ones larger, all more or less adherent at the base; petals convolute at the base, forming a tube, linear-lance-shaped and spreading at the top; stamens hypogynous, distinct, the filaments thread-shaped, the anthers sagittate, protruded beyond the corolla. The ovary is superior with a thread-like style and three linear fringed stigmas coiled up spirally. The fruit is an ovate capsule, dehiscing by three valves, which expose a central column bearing the numerous seeds, each provided with a hair-like appendage. Two species are in cultivation, one especially, *B. Juncea*, a graceful plant, from its elegant drooping grass-like leaves. The same name has also been applied to a genus of *Amaryllidaceæ*, now included under *Littœa*. [M. T. M.]

**BONATEA.** Under this name are collected many species of terrestrial Orchids, with the oblong fleshy roots of our wild *Orchids*. The genus is perhaps not distinct from *Habenaria*, from which it is only separated by an excessive enlargement of the upper lip of the stigma. The true lip is always divided to the very base into thread-like lobes. The flowers appear to be in all cases greenish, varying on yellow or white.

**BONAVERIA.** A genus of the Pea-flower family (*Leguminosæ*), consisting of a single species, *B. acutipera*, formerly placed in the genus *Coronilla*, with which it accords entirely in habit, but differs in the form of the pod, which is about four inches long by a quarter of an inch wide, flattened, thickened at both margins, and not jointed distinctly between the seeds. In *Coronilla*, on the contrary, the pod is nearly cylindrical, and distinctly jointed. The plant grows in South Europe, and is a smooth pea-green herb a foot or more high, with unequally pinnate leaves five or six inches long, made up of many pairs of wedge-shaped leaflets; the yellow flowers

are borne in an umbellate manner at the end of a long naked stalk, the umbels being about half an inch across. It is often seen in collections of herbaceous plants, and is frequently called *Securigera Coronilla*. [A. A. B.]

**BONE-SEED.** The common name for *Osteospermum*.

**BONESET.** *Eupatorium perfoliatum*:

**BONGARDIA.** A genus of the berberry family, but not at all like a berberry in appearance. One species only (*B. Rauwolfii*) is known, and it is a small stemless plant, with a tuberous underground rootstock, somewhat like a small potato, from the upper part of which spring four or five long-stalked pinnatisect leaves. The flower-stalk is slightly branched and panicle, and the flowers small, golden yellow, with three to six calyx leaves, and six petals, each of which has a little pit at its base, like that of the buttercup. The genus comes near to that of the lion-leaf (*Leonotis*), but differs in the pit at the base of the petals, and in having a dilated stigma. The plant is a native of Greece, Syria, and Persia, extending to Afghanistan and Scind. It was noticed as early as 1573 by Rauwolf, who spoke of it as the true *Chrysogonum* of Dioscorides. The Persians roast or boil the tubers, and use them as an article of food, while the leaves are eaten like sorrel. [A. A. B.]

**BONHOMME** (Fr.) *Narcissus pseudo-Narcissus*; also *Verbascum thapsiforme*.

**BONNAYA.** A small genus of *Scrophulariaceae*, found in tropical and sub-tropical Asia. They are annuals, usually glabrous, with opposite leaves, and flowers in the axils or terminal racemes. The calyx has five distinct narrow sepals; the upper lip of the corolla is erect and two-lobed, the lower is larger, spreading and three-lobed. The two upper stamens alone are fertile, the lower pair, inserted at the base of the lower lip of the corolla, are represented by the linear obtuse filaments. The style is filiform with a dilated generally two-lobed stigma. The linear capsule is longer than the calyx. [W. C.]

**BONNE DAME.** (Fr.) *Atriplex hortensis*.

**BONNET DÉLECTEUR or DE PRÊTRE.** *Cucurbita Meloepo*; also *Eucynimus europæus*.

**BONNETIA.** A genus of the Tea family (*Ternstroemiaceae*), composed of a few Brazilian and Peruvian shrubs or small trees, with sessile spatulate entire leaves, having prominent parallel veins; they are generally crowded at the ends of the branches, which are marked with prominent scars where they have fallen. The flowers are numerous and panicle, or single, and as large as those of *Camellia*; generally white in colour, and composed of a five-leaved calyx, five petals, a large number of stamens, a three-parted style, and a one-celled ovary, which becomes when ripe a three-celled capsule containing

many seeds. The leaves of *B. paniculata*, a Peruvian species which attains the height of twenty or thirty feet, have an aromatic smell when bruised. [A. A. B.]

**BONPLANDIA.** A genus of *Rutaceae*, now generally merged in *GALIPEA*; which see. [M. T. M.]

**BONTIA.** A genus of *Myoporaceae*, containing a single species from the West Indies. It is a small evergreen tree, in habit so like the olive as to have been named *Olea sylvestris*. The leaves are alternate lanceolate and sub-entire, and the flowers are solitary or in pairs on axillary pedicels. The calyx is divided into five ciliated imbricated lobes, two being exterior. The corolla is tubular and bilobate. The four didynamous stamens are shorter than the corolla. The ovoid ovary is two-celled, each cell being almost divided by an incomplete secondary septum; there are two ovules in each cell. The lacinate drupe has eight hard seeds. [W. C.]

**BONUS HENRICUS.** Good King Henry, *Chenopodium Bonus Henricus*.

**BOOPTA.** A genus of the *Calyceae* family comprising a few annual or perennial herbs, some of them stemless and with entire leaves, others branching with pinnatisect leaves, and a habit not unlike that of the chamomile. Their flower heads are stalked and terminal, containing many white or yellow florets enclosed by a membranous toothed involucre. The genus is readily distinguished from its allies by the absence of spiny points to the calyx leaves, and the nature of the involucre. The species, eight in number, are found in the Cordilleras of Chili, the neighbourhood of Buenos Ayres, and also in the extreme south of the continent. The generic name is derived from the Greek *bous*, an ox, and *ops*, an appearance; the flowers having somewhat the appearance of an ox-eye. [A. A. B.]

**BOOREE.** An Indian name for the inflammable pollen of a species of *Typha*.

**BOOR-TREE or BOUNTRY.** A Scotch name for the Elder, *Sambucus nigra*.

**BOOTIA.** A genus of the natural order *Hydrocharidaceae*, found in the margin of the river Irrawadi in Ava. The leaves are all radical, some of them submersed, elongate linear-lanceolate, others cordate, floating, with long petioles and a scape rising out of the water; flowers dioecious from a tubular inflated spathe, which is toothed at the apex, and includes many stalked male flowers or a single sessile female one. Perianth with three outer oblong calyx-like divisions, and three inner obovate petaloid ones. As usual in the order, these segments are in the female flower at the top of a tube adhering to the ovary at the base. Stamens twelve; ovary with nine parietal placentas. [J. T. S.]

**BOQUILA.** *B. trifoliata*, the only known species, is a small dioecious trailing shrub,

found in Chili in the neighbourhood of Valdivia, and there called *Boquil-blanca*, whence the generic name. Its leaves are alternate, with three entire or slightly-toothed leaflets which are glossy above and pea-green underneath. The flowers are white and solitary, or sometimes two or four, in the axils of the leaves; the calyx and corolla each of three membranous leaves; the male flowers containing six stamens and the females three or six ovaries, which when ripe are berries about the size of a pea, and with few seeds. The few seeds and membranous floral scales distinguish the genus from *Lardisabal*, to which it is allied. [A. A. B.]

**BORA.** A common Indian pulse, *Dolichos Cajan*, or *Cajanus bicolor*.

**BORAGE.** *Borago officinalis*.

**BORAGEWORTS.** A name applied by Lindley to the boraginaceous family.

**BORAGINACEÆ.** (*Borageworts*; *Asperifoliæ*.) A natural order of Corollifloral Dicotyledons or Exogens belonging to Lindley's Echioal alliance. Herbs or shrubs with round stems, alternate rough leaves, and spirally-coiled inflorescence; calyx four to five divided, persistent; corolla generally regular and five-cleft; stamens five, inserted in the corolla, and alternate with its divisions; ovary four-lobed with a style arising from the base of the lobes. The fruit consists of distinct achenes without albumen. The order was called formerly *Asperifoliæ* from the rough leaves of the plants. Natives of the northern temperate regions principally. They abound in the southern part of Europe, the Levant, and middle of Asia. They are less frequent in high northern latitudes, and they nearly disappear within the tropics. Demulcent mucilaginous qualities pervade the order. Some yield dyes, as alkanet (*Achusa tinctoria*); others are used for potherbs, as comfrey (*Symphytum officinale*), which is employed as a substitute for spinach. The common borage (*Borago officinalis*), when steeped in water, imparts coolness to it, and is used in the beverage called cold-tankard. The leaves of *Mertensia maritima* have the taste of oysters, so that it is called the oyster-plant. The species of *Myosotis* receive the name of Forget-me-not. There are fifty-eight known genera, and 688 species. Illustrative genera:—*Cerinth*, *Echium*, *Borago*, *Lithospermum*, *Cynoglossum*, *Myosotis*, *Symphytum*, *Anchusa*, *Omphalodes*. [J. H. B.]

**BORASSUS.** There are only two species of this magnificent genus of Palms, both having separate male and female flower-spikes on distinct trees: the males in cylindrical branching catkins, composed of a number of scales closely packed and overlapping each other, from amongst which the flowers only partially emerge; the female spikes seldom branched, and their scales not so closely packed as those of the male.

*B. flabelliformis* is the Palmyra Palm. The

parts of this tree are applied to such a multitude of purposes that a poem in the Tamil language, although enumerating 801 uses, does not exhaust the catalogue. It is widely distributed throughout the tropical parts of Asia, generally growing in low sandy tracts of land near the sea-coast, and forming lofty trees with straight and almost cylindrical trunks from sixty to eighty or even one hundred feet high, and about two feet in diameter. Like all endogenous trees, it has the hardest part of its wood towards the outside of the trunk, and the older the tree the harder this wood becomes; so that, while the wood of young trees is almost worthless, that of centenarians is very valuable on account of its hardness, weight, and durability. The leaves of the Palmyra are from eight to ten feet long, including the stalk, and of a nearly circular form, consisting of seventy or eighty ribs, radiating from a centre and plaited like a half-open paper fan: in old trees they form a large round head at the summit of the trunk. These leaves are employed by the natives for a variety of useful purposes; houses are thatched with them; matting for floors and ceilings is platted from strips of them, also bags and baskets of all kinds, hats and caps, umbrellas and fans, and a host of minor articles; they likewise, in common

*Borassus flabelliformis.*

with those of the Talipot palm, supply the Hindoo with paper, which he writes upon with a stylus. A most important product, called toddy or palm-wine, is obtained from the flower-spikes in the following manner: as soon as a spike makes its appearance among the leaves, a toddyman ascends the tree, and securely binds it with thongs so that it cannot expand; he then for three successive mornings beats the lower part of the spike with a short baton, and on the four following mornings, in addition to the beating, he cuts a thin slice off the end; on the eighth day the sap or toddy begins to flow and is collected in a

earthenware jar tied on the end of the spike. A tree continues to yield toddy for four or five months, the toddyman ascending the tree every morning to empty the jar, and at the same time to cut a fresh slice off the end of the spike. Palm toddy is intoxicating, and when distilled yields strong arrack. Very good vinegar is also obtained from it; but its most important product is jaggery, or palm-sugar, large quantities of which come to this country. The fruits of this palm are about the size of a child's head, and are produced in bunches of fifteen or twenty together. They have a thick coating of fibrous pulp, which the natives roast and eat, or make into a jelly. But the most singular use of this palm is the consumption of the young seedlings as an article of food; these are cultivated for the market, and either eaten in a fresh state or after being dried in the sun, or else they are made into a very nutritious kind of meal.

*B. ethiopus* is a native of the central part of tropical Africa, occurring from the Niger on the west to Nubia on the east. It forms a large tree resembling the *Palmyra* in general appearance, but having a curious bulging out or swelling in its stem at about the middle of its height. Its leaves and fruits are used by the Africans for the same purposes as those of the *Palmyra* by the Asiatics, and its young seedlings are likewise used for food; but the custom of extracting toddy does not appear to be known in Africa. [A. S.]

**BORONIA.** A genus of the Pea-flowered section of the Leguminous family, numbering thirteen species, all of them natives of South Africa. They are small shrubs with simple alternate many-nerved leaves. The flowers, arranged in axillary or terminal few-flowered racemes, are yellow, as in those of the common broom, and much like them but smaller. The pods are linear compressed and often covered with long soft hairs, and contain few seeds. The segments of the calyx are equal, and the upper petal or vexillum is hairy; these two characters distinguishing the genus from its allies. *B. crenata* has roundish leaves which embrace the stem by their base, and terminal racemes of pretty yellow blossoms. *B. parviflora* has many-nerved sharp-pointed leaves like those of the butcher's-broom (*Ruscus*). The genus was named in honour of Gaston de Bourbon, Duke of Orleans, son of Henry IV. of France, a patron of botany. [A. A. B.]

**BORBOOLE.** A loose or open-headed variety of the Cabbage, *Brassica oleracea*, cultivated in gardens under the name of Kale.

**BORKHAUSIA.** A family of compound flowers allied to the Hawkweeds and Dandelion. Several species are described as inhabiting Southern Europe, all of which are annuals. Two are natives of Great Britain, but are of rare occurrence. The group to which they belong is one very

difficult of discrimination, and will scarcely admit of a satisfactory popular description. They have yellow flowers, and leaves somewhat like those of the Dandelion. *B. fatida* has an unpleasant odour, in which a flavour of bitter almonds can be distinguished. *B. rubra*, an Italian species, is cultivated as a border plant; it has compound leaves and large flowers of a delicate rose colour or sometimes white. (French: *Barkhausia*.) [O. A. J.]

**BORONIA.** This name was applied in honour of Francis Borone, an Italian attendant of Dr. Sibthorp, of *Flora Græca* celebrity, to a genus of *Rutaceæ*. The genus is known by a four-cleft persistent calyx; four ovate persistent petals; eight stamens, of which the four opposite the sepals are fertile, the remaining four abortive, with filaments studded with hairs and bent inwards; four styles, erect, approximate or fused together; carpels four to two-valved, combined within into a four-celled capsule; seeds few in each cell, flattened. The species are shrubs, natives of New Holland, with opposite pinnate leaves and pretty pinkish or whitish flowers. Many of them are in cultivation as elegant greenhouse shrubs. [M. T. M.]

**BORYA.** The same as *Forestiera*.

**BOSCHIA.** Louis Bosc was a French professor of agriculture, and in his honour this genus of *Capparidaceæ* was named. The plants have four sepals disunited or joined together at the base only; petals none; stamens twelve to twenty; berry globose, stalked, one-seeded; leaves simple. The species are natives of Africa. *B. senegalensis* is in cultivation as an ornamental stove-plant. [M. T. M.]

**BOSEA.** A genus consisting of a shrub from the Canary Islands, of which the natural order is doubtful, but most generally supposed to be *Chenopodiaceæ*. The leaves are alternate, exstipulate, shortly-stalked, elliptical-acuminate, and shining; racem. : axillary and terminal, the flowers small polygamous-dioecious; perianth five-cleft, membranous, with two bracts; stamens five; ovary one-celled; drupe subglobose, fleshy; embryo with foliaceous cotyledons. [J. T. S.]

**BOSSÉD.** Circular and flat, with a prominent centre, like the Highland target; as in the fruit of *Paliurus australis*.

**BOSSIEA.** A genus of Australian shrubs or small herbs belonging to the Pea-flowered section of the Leguminous family. Their stems are round or compressed, often when compressed without leaves; the leaves are simple, of various forms, and the flowers are axillary and solitary, always yellow, the base of the vexillum or the keel generally blotched or veined with purple. The genus differs from its allies in its alternate leaves and compressed pods, the margins of which are thickened but not winged. It is named in honour of M. Bossieu Larmartinière, a French botanist, who accompanied La Peyrouse in his

voyage round the world. Many of the species are highly ornamental, and no greenhouse collection of any pretensions is to be found without some of them. Among the leafless species in cultivation are *B. scolopendria* and the sword-branched *B. ensata*; both these, however, when in a seedling condition, have true leaves. Amongst the leafy species the choicest are the slender-stemmed *B. tenuicaulis*, with ovate acute leaves and very numerous yellow flowers streaked with purple; *B. lanceolata*; and *B. disticha*, a Swan River species, with ovate acute leaves arranged in a two-ranked manner. [A. A. B.]

**BOSTRYCHIA.** A genus of rose-spored *Algae* belonging to the natural order *Rhodomelaceae*, and remarkable at the same time for the curled tips of the fronds, and their amphibious habit like that of *Lichina*. *B. amphibia* occurs on our coasts as high as the Wash, extending from thence to Spain; it grows attached to the base of marine phænogamous plants, which are covered only at high water. Several species grow in the United States in similar situations or on the margins of tidal rivers, and others are found nearer the equator and in the Southern hemisphere. They do not agree in the structure of the frond, but their habit and general character are so alike that it is better not to separate them. [M. J. B.]

**BOSWELLIA.** A genus of the family *Amyridaceae*, consisting of trees with compound leaves; and white flowers in clusters, each with a small five-toothed persistent calyx, and five petals spreading widely, inserted, as are also the ten stamens, beneath a cup-shaped fleshy disc, which is larger than the calyx; the filaments of the stamens are persistent, but the anthers fall off. Ovary sessile, with a long style, terminated by a three-lobed stigma. The fruit is triangular, three-celled, and bursts by the separation of the three component leaves one from the other; the seeds are winged. These trees are remarkable as furnishing a gum resin. That of *B. glabra* is used in India in place of pitch, and as a medicine, both externally and internally. The Hindoos employ it as incense in their religious ceremonies.

*B. thurifera*, a tree common in Commaudel, also known as *B. serrata*, furnishes the resin known as Indian Olibanum, which is supposed to have been the Frankincense of the ancients. It is rarely used in medicine, but is an astringent and stimulant, and is employed for its grateful perfume as incense in Roman Catholic churches. African Olibanum, a drug rarely met with in this country, has been shown by Dr Birdwood (*Trans. Lin. Soc.*, xxvii. 11) to be the product of *B. Carteri*, *B. Bham-Dajiana*, and *B. Proreana*, the two former yielding the 'Laban-Theberi,' the latter the 'Louban Maitee' of the Somalis. See Dr Birdwood's paper above referred to. The two first-mentioned species are in cultivation in our stores. [M. T. M.]

**BOTHRENCHYMA.** The pitted, or dotted, or so-called porous tissue of plants.

**BOTROPHIS.** A genus of *Ranunculaceae*, synonymous with *Macrotis*, containing a North American herb allied to *Cimicifuga*, from which it differs by having only one carpel (very rarely two), which becomes a solitary follicle in fruit. This distinguishes it from the berry-bearing *Actaea*. The leaves are twice or three times ternate, with large oval leaflets irregularly cut; the stem is about from three to eight feet high, with long racemes of white flowers, of which the central one is by far the longest: sepals petaloid, white, soon dropping off; petals, or rather abortive stamens, very small with long claws; stamens numerous, white, and very conspicuous; seeds seven or eight in the follicle. The flowers are very fetid, and the large knotted root-stocks, which have a nauseous astringent and bitter taste, are considered in the United States to be a remedy for the bite of the rattlesnake. The only species rejoices in several names both generic and specific. [J. T. B.]

**BOTRYCHIUM.** A genus of *Ophloglossaceae* Ferns, distinguished by having the fructifications in a compound or rachiform panicle, forming a separate branch of the frond. The spore-cases in this group have no jointed band or ring surrounding them, as in the generality of ferns, but are fleshy, coriaceous, and burst vertically in two equal hemispherical valves. The fronds spring from a short erect fleshy rhizome, and are variously pinnatifid, pinnate, or ternately decompound, the sterile and fertile branches being always separate, and the spore-cases ranged in two rows on the ultimate divisions of the latter. The genus, which consists of about a dozen species, is found in all parts of the world excepting Africa, and extends from the tropical to the arctic regions, and over both the eastern and western hemispheres. The common British species, *B. Lunaria*, called Moonwort, is a dwarf fleshy-looking plant, having the sterile branch pinnate with lunate leaflets, and the fertile branch panicled with sessile distinct globular spore-cases. *B. simplex* is a smaller and less divided plant found in North America and the north of Europe. Another species, *B. virginicum*, of which somewhat varied forms are found in North and South America and in India, is much larger in size and more compound in structure than either of the foregoing; the sterile branch being ternate, then bipinnatifid, with the segments again inciso-pinnatifid, and the fertile branch larger and bipinnate or tripinnate. [T. M.]

**BOTRYDIUM.** A genus of green-spored *Algae* belonging to the division *Siphoniet*, in which it is remarkable for the predominance of the large capsule over the vegetative part, which consists only of a few threads, that like roots penetrate the soil, the capsules being the only part externally visible. *B. granulatum* occurs in

little vesicular strata on the sides of ponds, but not very commonly. [M. J. B.]

**BOTRYODENDRON.** *Noryta*.

**BOTRYOGRAMMA.** *Liavea*.

**BOTRYOPSIS.** A genus of *Menispermaceae*, described by Mr Miers. The male flowers have six petals; the female flowers six ovaries, with an embryo without albumen, and curved so as to resemble a horse-shoe; cotyledons large, thick, curved; radicle superior. The plants are natives of the Organ mountains of Brazil. [M. T. M.]

**BOTRYOPTERIS.** A synonym of *Helmintotheca*.

**BOTRYOSICYOS.** A name apparently implying a resemblance in the plant to which it is applied, to a grape vine and a gourd. The genus is said to belong to the order *Dioscoreaceae*. The flowers are dioecious. The male flowers are very small, in clusters concealed by an involucre; the perianth is bell-shaped, six-cleft, in two rows, the three outer hairy, shorter than the inner, which are petal-like. Within this are three scales adherent at the base to the inner divisions, and similar to them, but shorter and divided into two teeth or lobes at the apex. Stamens three, inserted near the throat of the perianth; filaments short, bearing the anthers, which are two-celled, introrse; ovary abortive; stigma three-toothed. The female flowers and fruit are not known. The plant is a climber, and a native of Abyssinia. [M. T. M.]

**BOTRYOTHALLUS.** A name applied to one or two Acrostichaceous Ferns included in *Polypodium* and *Soromanes*.

**BOTRYPUS.** A synonym of *Betrychium*.

**BOTRYS.** The term applied in Greek compounds to the raceme. A bunch.

**BOTRYS.** (Fr.) *Chenopodium Botrys*.

**BOTRYTIS.** A genus of filamentous moulds first proposed by Michell, but now so divided that the original genus is almost swamped. Amongst those best known is the parasite which plays so important a part in the virulent potato murrain under the name of *B. infestans*; as, however, there are strong reasons for separating this and a host of allied plants, we must refer for their consideration to the article *PERONOSPORA*. The disease in silkworms called muscardine is produced by a mould called *B. Bassiana*, but this also in all probability will ere long find its place in some other genus, perhaps in *Botryosporium*. A few of the spores rubbed upon the skin of the caterpillar, or inserted carefully with a lancet, are sufficient to inoculate the animal. The spores soon germinate, and their threads prey upon the fatty tissue, till the caterpillar becomes mummified and resembles certain pastilles, from whence the name of the disease has been borrowed. In the silkworm houses

the malady most commonly commences in the large intestine, as if from the germination of swallowed spores. The prevention of the disease consists in the most perfect cleanliness, and every precaution which may destroy the spores or prevent their access. [M. J. B.]

**BOTULIFORM.** Sausage-shaped.

**BOUCAGE.** (Fr.) *Pimpinella*; also *Enanthe pimpinelloides*.

**BOUCHEA.** A genus of *Verbenaceae*, containing fourteen species of herbs or undershrubs, natives of America, Africa, and Asia. They have sub-sealike flowers in a spicate raceme, which is either terminal or in the forking of two branches. The calyx is elongate tubular, with five ribs produced into small teeth, and five alternate furrows, and truncate between the teeth. The corolla is funnel-shaped. The four included didynamous stamens are inserted in the throat of the corolla. The ovary is two-celled, with a single anatropal ovule in each cell; the style is as long as the stamens. The capsule is surrounded by the persistent calyx; it is dicocious and has numerous seeds. [W. C.]

**BOUGAINVILLEA.** A genus of the natural order *Nyctagynaceae*, characterised by the flowers being almost concealed by large membranous or leafy bracts, which grow in triplets, and form magnificent masses of pinnate inflorescence. The perianth is tubular with a short limb; the stamens are seven or eight in number; the style lateral; the stigma thickened. *B. spectabilis* is a climbing shrub or small tree, with alternate leaves and small spines; the bracts are large and of a rich rose colour; hence the pendent inflorescence is singularly handsome. The colour of the bracts varies. The plant is a native of tropical South America. [M. T. M.]

At least two other species of this gorgeous genus are grown in our gardens, *B. speciosa*, which has hairy leaves and stems, the latter furnished with strong short recurved thorns, and dense panicles of large soft rosy-tinted bracts; and *B. glabra*, which is of more slender habit, with smaller leaves, both these and the stems being nearly smooth, and bearing its showy bracts, which are of a lighter rose and rather smaller than in *B. speciosa*, in more open panicles. [T. M.]

**BOUGUERIA.** A genus of *Plantaginaceae*, containing a single species, a native of Peru. It is a small perennial fleshy-rooted herb, growing in tufts, and having white linear leaves, and axillary peduncles, bearing compact heads, which blacken in drying. The flowers are polygamous, both sexes occurring on the same head. This genus occupies a position between *Plantago* and *Littorella*. [W. C.]

**BOUILLARD.** (Fr.) *Betula alba*.

**BOUILLON-BLANC.** (Fr.) *Verbascum thapsiforme*.

**BOULE DE NEIGE.** (Fr.) *Fiburnum Opuncus*, with double flowers; the term is also applied to *Agaricus arvensis*.

**BOULEAU COMMUN.** (Fr.) *Betula alba*. — **ODORANT.** *Betula lenta*.

**BOULETTE AZURÉE.** (Fr.) *Echinops Ritro*.

**BOUNCING BET.** An American name for *Saponaria officinalis*.

**BOUQUET PARFAIT.** (Fr.) *Dianthus barbatus*, the common Sweet William.

**BOURBONNAISE.** (Fr.) *Lychnis Viscaria*.

**BOURDENE, or BOURGE'NE.** (Fr.) *Rhamnus Frangula*.

**BOURGOGNE.** (Fr.) *Hedysarum Onobrychis*.

**BOURRACHE.** (Fr.) *Borago officinalis*. — **PETITE.** *Cynoglossum Onchalodes*, or *Onchalodes verna*.

**BOURREAU DES ARBRES.** (Fr.) *Celastrus scandens*. — **DU LIN.** *Cuscuta epithimum*.

**BOURSETTE.** (Fr.) *Valerianella oltoria*.

**BOUSSINGAULTIA.** A name given in honour of a French philosopher, and applied to a genus of *Basellaceae*. The plants have a perianth of six to eight pieces, and two small bracts on the outside; six stamens opposite the sepals; ovary elliptical; style thread-shaped, thickened at the base; stamens three, club-shaped. Fruit roundish, compressed, membranous, one-seeded, indehiscent, crowned with the persistent style; seed kidney-shaped, smooth, sessile. *B. baselloides*, a native of the Andes, is an elegant climbing shrub, with alternate entire fleshy leaves, long clusters of fragrant whitish flowers, and thick fleshy roots. It is well adapted to trail over trelliswork. [M. T. M.]

**BOUTILLEAU.** (Fr.) A kind of olive.

**BOUTINIANE.** (Fr.) A kind of olive.

**BOUTON D'ARGENT.** (Fr.) *Ranunculus platensis*, with double flowers; also *Achillea Ptarmica*. — **DOR.** *Ranunculus acris*, with double flowers. — **ROUGE.** *Cercis canadensis*.

**BOUVARDIA.** One of the genera of *Cinchonaceae*, named in honour of Dr. Bouvard, a former superintendent of the Jardin du Roi, at Paris. It is distinguished by a calyx with a sub-globose tube, a limb of four linear awl-shaped lobes, occasionally with little teeth intermediate between the lobes; a funnel-shaped corolla, naked at the throat, and with a four-parted spreading limb; filaments adherent for some distance to the tube of the corolla; anthers linear, included; stigma divided into two lamellae projecting beyond the tube of the corolla; capsule membranous, globose, compressed, with two compart-

ments opening through the backs of the carpels by two valves; seeds numerous, winged. The plants are Mexican shrubs, with handsome flowers in terminal corymbs. Most of the species have red flowers, but in *B. longiflora* they are large white and fragrant; and in *B. flava* they are yellow. *B. triphylla* has three leaves with stipules between their petioles, thus presenting an approximation to the structure of the *Galiaceae* or *Stellatae*. [M. T. M.]

**BOVA.** A kind of Vanilla.

**BOVISTA.** The small smooth nearly globose Puffballs which are so common in our fields and in large exposed pastures, distinguished by their having an outer coat which easily separates from the thin inner covering, belong to this genus, which contains also a few tropical and subtropical species. The smaller of these, *B. plumbea*, is one of our lesser puffballs, and is easily known by its leaden hue when dry; the larger, *B. nigrescens*, by the far firmer and darker inner coat. Both are eatable when young, but our own experience is not in favour of their use, as they are apt to have an unpleasant taste, if they have reached their full growth. Some of the foreign species have violet or russet spores, instead of the more sober hue of our own natives, one of which is commonly sold in the bazaars of the Deccan and Birmah. In all the species it would seem that the spores are seated on a short stalk, but this is not without example in *Lycoperdon*. [M. J. B.]

**BOWDICHIA.** A genus which belongs to the Pea-flowered tribe of the Leguminous family. The species are found in South America, and are chiefly confined to Brazil. They are trees with alternate unequally-plumate leaves, with from five to fourteen pairs of leaflets, which vary from half an inch to two inches long, and are often pubescent underneath. The flowers are very numerous, disposed in terminal panicles, and violet in colour. The pods are stalked, thin and papery in texture, containing six to eight seeds.

*B. nitida*, a Brazilian species, is a tree about fifty feet in height, with a diameter of one foot, the wood of which is exceedingly hard. Another Brazilian species, *B. virgiloides*, is one of the commonest trees of the Campos, and a great ornament to them, the upper part being clad with flowers of the finest amethystine blue, while the leaves are confined to the lower branches, the upper having fallen off. The bark is of a reddish-brown colour, and is known as Alcorooco bark. It is astringent, slightly bitter, and gives to the saliva a yellow colour. It was once recommended in pulmonary consumption, but its use is now obsolete. All the parts of *B. major* are said to have tonic qualities. The genus bears the name of J. E. Bowdich, who travelled in West Africa. [A. A. B.]

**BOWMAN'S ROOT.** *Imardia alternifolia*; also *Gillenia trifoliata*.

**BOWRINGIA.** A genus of leguminous plants, allied to *Buphia*, and consisting of a single species, which forms a smooth scandent shrub, with unifoliate leaves, the leaflet of which is ovate or oval-oblong and acuminate; it bears short axillary or subterminal racemes of from two to five small white pea-shaped flowers. The plant is abundant in the island of Hong Kong. The name has also been given to a genus of Ferns, now referred to *BRASSEA*: which see.

[T. M.]

**BOW-WOOD.** An American name for *Maclura aurantiaca*.

**BOX** *Buxus* —, **BASTARD.** *Polygala Chamæbuxus* —, GREY, of Victoria. *Eucalyptus dealbata* —, QUEENSLAND. *Lophostemon macrophyllus* —, R.D., of N. S. Wales. *Lophostemon australis* —, NEW-RIOUS, of Victoria. *Eucalyptus leucogylon* —, TASMANIAN. *Bursaria spinosa* —, WHITE, of Australia. *Eucalyptus nitens* —, YELLOW, of Australia. *Eucalyptus melliodora*.

**BOX ELDER.** *Negundo fraxinifolium*.

**BOX-THORN.** *Lycium*.

**BOXWOOD, AMERICAN.** *Cornus florida* —, JAMAICA. *Tecoma pentaphylla*.

**BOYKINIA.** A genus of perennial North American herbs, belonging to the natural order *Saxifragaceæ*, with alternate stalked palmately five or seven-lobed or cut leaves; flowers white, in cymes. It differs from *Saxifraga* by having the calyx (which adheres to the ovary) contracted at the top, and by having only five stamens. It also differs from *Silene* by the calyx adhering completely to the ovary, and from *Heuchera* and *Tiarella* by the ovary being two-celled.

[J. T. S.]

**BRADJUM.** A genus of *Proteaceæ*, with apetalous flowers of four sepals, and four anthers on short filaments, attached to the base of the sepals. The flowers are borne on axillary spikes of about four inches in length. The seed-vessel is an elliptical nut, containing a single seed. The leaves are verticillate, about four inches in length, and one inch broad, remotely serrated. *B. stellatifolium*, which attains the height of from six to eight feet, is a native of South Africa; its seeds are called Wild Chestnuts, and Wild Almonds, and are both roasted and eaten, and used as a substitute for coffee. The tree is also called Caffre Chestnut by the colonists.

[R. H.]

**BRACHIALIS.** An ell long; twenty-four inches long.

**BRACHIATE.** When branches spread, at nearly right angles, alternately in opposite directions.

**BRACHIUM.** An ell, or two feet.

**BRACHITIA.** A genus of South American Orchids, related to *Brassia*, of which it has the organs of vegetation. The flowers

are, however, very different. They are small, secund, half hidden by bracts, and densely arranged. In front of the ovary, and forming part of it, is a hollow tumour like a goitre, from the superior edge of which rises a simple bilamellate lip. There is no tendency to the tail-like extension of the sepals and petals, so characteristic of *Brassia*. Three species are known. The genus has also been called *Oncodia*.

**BRACHYCARPÆA.** A genus of *Cruceifera*, allied to *Senebiera*. It consists of undershrubs from the Cape of Good Hope, with oblong or linear entire mucronate leaves, and elongated racemes of large yellow or purple flowers; pouch two-celled, constricted in the line of junction of the two portions, sub-compressed, tuberculate, indelhiscent, each end with one seed.

[J. T. S.]

**BRACHYCHITON.** A genus of tropical, or sub-tropical Australian trees, belonging to the Sterculiaceæ family, with alternate entire or variously lobed leaves, which are either smooth or covered with starry pubescence. The flowers are sometimes produced from the old wood two or three together, but more generally in terminal panicles, and have a tubular coloured calyx, without corolla. They are male and female on the same plant, the males having a great number of stamens, the stalks of which are more or less united, and the anthers packed in a round mass. The fruit is composed of five woody follicles, clothed inside with starry hairs, as also are the seeds, which are numerous. *B. acerifolium* is called the Flame Tree about Illawarra, on account of its bright red flowers, which make the tree a conspicuous object at a distance. It attains a height of from 60 to 120 feet, and a diameter of two to three feet. The bark is used by the aborigines for making fishing-nets, and the wood is soft and spongy. *B. populneum* is found in Eastern tropical Australia, and grows to a height of thirty or fifty feet, with a diameter of from eighteen to thirty-six inches. Its leaves are smooth, on long stalks, generally ovate and long pointed, but sometimes trilobed. The wood is soft, and contains gum mucilage. The tap roots of the young trees, as well as the younger roots of the large trees, are used by the natives as an article of food. The seeds are eaten, and the bark is put to the same uses as that of the maple-leaved species. *B. Bidwillii*, a native of the Wide Bay district, was sent to England in 1851 by Mr. Bidwill. Its leaves are stalked, heart-shaped, entire or three-lobed, and covered with a soft pubescence. The flowers are of a bright red colour, and are arranged in axillary bunches. The stems of this species show a tendency to become gouty, like those of the nearly-related 'Gouty-stemmed tree' of Australia (*Dalechsea*). Five species of the genus are known.

[A. A. B.]

**BRACHYCOME.** An Australian genus of Compositæ, belonging to the *Helio*

section of the order, and comprising several neat annuals, of dwarf habit. Of these the most interesting is the *B.iberidifolia*, or Swan River Daisy, an elegant little plant, of branched diffuse habit, with deeply-cut foliage, having the segments linear, and loose terminal corymbs of cineraria-like blossoms, each nearly an inch across. The colour of the ray florets varies from violet blue to white, the disk or centre being in all cases of a purplish brown. *B. glabra*, of more recent introduction, has solitary flower-heads or long foot-stalks, about as large as those of *iberidifolia*, with a white ray of numerous linear florets, tinged with violet beneath, and a yellow disk: its foliage is pinnatifid, with linear segments variously cut, the uppermost ones being nearly entire, and all rather fleshy, and ciliated. The only other species in cultivation is *B. diversifolia*, with yellow flower-heads, rather smaller than in either of the preceding species, and foliage variously cut and lobed, as the specific name implies. The genus is characterised by a slightly conical, pitted, and naked receptacle; a cup-shaped involucre, the scales of which are membranous at the margins; and laterally compressed fruit, crowned with a pappus of very short bristle-like hairs. [W. T.]

**BRACHYLOTTIS.** The plants which composed this genus have been shown to differ in no way from the Groundsels (*Senecio*), and are now generally referred to that genus; yet, although the characters of the flower indicate this structural affinity, they have little resemblance to any of the species of *Senecio* found in Europe, for they are trees or small shrubs, with woody stems, which are covered, as well as the under surface of the thin leathery leaves, with long or short dense woolly hairs. *B. Forsteri* has large broad deeply-toothed leaves, and terminal panicles of numerous small yellow flower-heads. It is a native of New Zealand, as are all the species, and is there known as Puka-Puka by the natives, who use the leaves as paper, whence the same native name came to be applied by them to English paper. [A. A. B.]

**BRACHYLENA.** A genus of South African evergreen shrubs, numbering six species, and belonging to the Compositae family. Their leaves are stalked, alternate, entire or toothed, generally smooth above, and covered with short white pubescence underneath. The flower-heads are arranged in terminal panicles or racemes—those on one plant containing female florets only, the males being on another. The florets are yellow in colour. The genus is nearly allied to the American genus *Baccharis*, but is readily distinguished from that by having tails to the anthers. [A. A. B.]

**BRACHYLEPIS.** A genus of *Asclepiadaceae*, containing a single species, a native of India. It is a climbing hairy shrub, with opposite acuminate leaves, and many small purple flowers in tomentose cymes, with numerous imbricated scales, on inter-

petiolar peduncles. The calyx and corolla are five-parted. The exerted stamens, with short broad filaments, are inserted along with the five scales of the staminal corona in the throat of the corolla. The anthers adhere to the lower margin of the stigma; their oval pollen masses united throughout the whole length of their inner surface by a flat membrane. The stigma is five-sided. The hairy follicles are widely separated, oblong and obtuse. [W. C.]

**BRACHYPODIUM.** A genus of Grasses, belonging to the tribe *Hordeaceae*, or barley grasses. The genus is chiefly distinguished from *Triticum* by the glumes being unequal, a circumstance which some authors do not consider of sufficient importance as a generic distinction; hence the species are referred either to *Triticum* or *Pastura*. Two are natives of Britain—the False Brome Grass, *B. sylvaticum*, and the Heath False Brome Grass, *B. pinnatum*. The former is a very common kind, which generally grows in shady woods, or on dry hedge banks; but the latter is rare, and only found wild in England. They are not grasses of agricultural importance, though useful in their natural localities. [D. M.]

**BRACHYPODOUS.** Having a short foot or stalk.

**BRACHYPTERYX.** A name indicative of the short wing borne by the fruits of this genus of *Malpighiadeae*. The species are natives of Brazil and Guinea, of climbing habit, with yellow flowers disposed in umbels. The calyx is five-parted, glandular; the petals unequal, longer than the calyx; the stamens ten, with a more or less enlarged glandular connective; the styles three, dilated at the apex into a rather large foliaceous recurved or hood-like and compressed mass. Fruit of three distended carpels (fewer by abortion), having at the apex a short compressed wing. [M. T. M.]

**BRACHYS,** in words of Greek origin, signifies short.

**BRACHYSEMA.** A genus belonging to the Pea-flowered section of the Leguminosae.

portia erect. The upper petal or standard being short compared with the others, gives rise to the generic name. The pods are stalked, ventricose, and many-seeded. *B. apyllum* is, as its name implies, without leaves, the branches being singularly compressed and winged, so as to perform the functions of leaves. Here and there on the branches small brown stipules are found, and from the axils of these the flowers grow; they are single, large, of a bright blood-red colour, and curiously reversed, the keel, or boat-shaped petal, usually lowest, being uppermost. Another leafless species, *B. pungens*, seldom grows more than a foot high, has innumerable spiny branches, and a dense mass of scarlet flowers, produced just above the ground, at the base of the stems. *B. lanceolatum* is a very handsome species, and a great ornament to greenhouses, flowering as it does in the winter or spring months. Its leaves are generally opposite, ovate or lanceolate

in form, with a glossy upper surface, and covered with silvery adpressed pubescence underneath. The flowers are in axillary clusters, large, and rich scarlet. [A. A. B.]

**BRACHYSORUS.** A name proposed for a Fern which proves to be *Asplenium sylvestricum*. [T. M.]

**BRACHYSTELMA.** A genus of South African *Asclepiadaceae*, containing several species of undershrubs, which have erect annual stems and large perennial tuberous roots. The calyx consists of five sepals; the corolla is campanulate and five parted. The staminal corona consists of five trilobed leaves attached to the middle of the gynostegium, which is included; while the anthers are simple and without a membrane, and the pollen masses roundish, and capped by a pellucid margin, at the base of which the two masses are attached to a slender corpuscle by two short processes. The two follicles are long and slender with numerous comose seeds. The roots are edible, those of some species being much esteemed as a preserve by the Dutch inhabitants of S. Africa. [W. C.]

**BRACKEN or BRAKE.** A common English name of *Pteris aquilina*.

**BRACTEÆ or BRACTS.** The leaves placed immediately below a calyx, if they are at all altered from their usual form.

**BRACTEATE.** Having bracts.

**BRACTEOLÆ, BRACTEOLÆ or BRACTEOLITES.** Bracts of a second order, usually smaller and more changed than the true bracts; also any small bracts.

**BRADBURYA.** The name given to a Texan herb which belongs to the Composite family. It is an annual plant with slender straight stems about three feet high, and altogether sparingly covered with hairs, which gives rise to the specific name *hirtella*. The leaves are numerous, linear, very narrow, and about an inch long; the flower-heads solitary at the ends of the branches, and the florets yellow. The genus bears the name of Mr. J. Bradbury, who travelled in America in 1809, and published some interesting notes on the botany of the Missouri country. [A. A. B.]

**BRAGANTIA.** A genus of *Aristolochiaceae*, consisting of undershrubs with decumbent wavy branches, thick leaves with prominent nerves, a regular flower with a thread-shaped calyx-tube adherent to the ovary, and a bell-shaped three-cleft limb; stamens six or nine, inserted on a shallow disc, surrounding the upper part of the ovary, and adherent to the base of the four connate styles; capsule pod-like, quadrangular, four-celled, four-valved, many-seeded. These plants are also remarkable for the structure of their wood, which differs considerably from the ordinary wood of *Eucalyptus*. They are natives of the tropical parts of Asia, and possess in some degree the properties of the *Aristolochias*. *B. tomentosa* is very bitter, and,

according to Dr. Horsfield, is used medicinally in Java. Major Drury in his work on the useful plants of India, says that the natives of the western coasts of India use the leaves and roots of *B. Wallichii*, rubbed up with lime juice, as a cure for snake bites; the whole plant mixed with oil in the form of an ointment is used in the treatment of inveterate ulcers. It used to be considered as an antidote to poison. A Malabar proverb says, as soon as the Alpin root, that is the root of this species, enters the body, poison leaves it. [M. T. M.]

**BRAHEA.** Certain fan-leaved Palms, inhabiting Peru, the Andes, &c., have been collected by Martius into a genus with the above name. They are trees of moderate height, with fan-like leaves and spiny leafstalks; flowers hermaphrodite, greenish, with a calyx of three sepals overlapping at the margins; six stamens, connate in a sort of cup around the base of the ovary. [M. T. M.]

**BRAHMIN'S BEADS.** An Indian name for the corrugated seeds of *Elaeagnus*, which are used by the Brahmins, and also made into necklaces, &c.

**BRAINEA.** A genus of polypodiaceous Ferns, now included in the group *Hemionitideæ*, in which it is distinguished by its primary veins anastomosing in an arcuate manner, so as to form a series of areoles next the costa, while the venule, which are parallel and oblique, are quite distinct to their apices. It has naked or non-induplicate sori continuous along the course of the transverse curved veins which unite to form the costal areoles, and often extended more or less along the parallel oblique free venules, becoming at length irregularly confluent.

*B. insignis* is the only species known. This is a native of Hong Kong, and forms a very handsome dwarf tree fern with a stem of three to four feet in height. The fronds are three feet long or more, pinnate, the pinna sometimes becoming pinnatifid; they are rigid and subcoriaceous in texture, and serrated along the margin. It is a very elegant and interesting plant. The genus has some points of resemblance to *Sadleria*, a genus of *Lomariaceæ*, but differs in having naked instead of induplicate sori, and in some other particulars. We had formerly regarded it as presenting a connecting link between the *Mentstrieæ* and the *Lomariaceæ*, through the *Woodwardiaceæ*, and had placed it in the former group in consequence of its short transverse naked sori; but now that more perfect specimens in the fresh state have been examined, we are quite ready to adopt the suggestion of Sir W. J. Hooker, that it may be referred to the *Hemionitideæ*, the sori not proving to be short and lunate, but continuous along the arcuate veins. It is, however, even here, somewhat anomalous, the fructifications being merely branched and not truly reticulated. 'We have here,' Sir W. J. Hooker observes, 'a very remarkable, and, if I may so say, a new form

among the Filices. In its arborescent caudex it reminds one of some of the cyatheaceous group of tree ferns, though not of one of the loftiest character; in its foliage it resembles several species of *Lomaria*; in its venation a *Woodwardia*, and in the more fully developed fructification an *Acrostichum*. [T. M.]

**BRAKES.** A common English name of *Pteris aquilina* and the related species or varieties. —, **ROCK.** *Allosorus crispus*.

**BRAMBLE.** The common name for *Rubus fruticosus* and the allied plants. —, **DOG.** *Ribes cynosbati*. —, **MOUNTAIN.** *Rubus Chamaemorus*, the Cloudberry.

**BRAMIA.** The title of a section of the genus *Herpestes* (*Scrophulariaceae*) characterised by having the upper lip of the corolla deeply bilobed. [W. C.]

**BRANCURSINE.** (Fr.) *Acanthus mollis*; also *Heracleum Sphondylium*.

**BRANDESIA.** A section of the Amaranthaceae genus *Telanthura*, which consists of tropical plants (chiefly American) allied to the globe amaranth of the gardens. *Brandesia* is distinguished from the other sections by not having the calyx distinctly jointed to the extremely short pedicel, and its segments being nearly equal. The flowers are each accompanied by three bracts, and are in long-stalked globose or ovoid heads; the stamens are united into a tube by the adhesion of the filaments. *B. porrigens* has the heads of flowers deep purple, resembling those of *Sanguisorba officinalis*, but dry like those of the 'everlasting' flowers. [J. T. S.]

**BRANDY BOTTLES.** A local English name for the flowers of *Nuphar lutea*.

**BRANK.** *Fagopyrum esculentum*.

**BRASSAVOLA.** In the tropics of America, and in no other part of the world, occur many species of Orchids with slender fleshy stems, solitary succulent usually pugioniform leaves, and large greenish flowers, with narrow acuminate or long-tailed petals, and a similar entire sometimes very broad lip. They have also a column with a pair of great falcate ears on each side of the front, and eight pollen masses. To these the name of *Brassavola* has been given. A few species have been added, in which the appendages or ears of the column are small and toothed. The most remarkable are *B. glauca*, with glaucous flat fleshy leaves, and very large flowers, from Mexico; and *B. Digbyana*, which differs in little, except having the margin of the lip broken up into long hair-like fringes.

**BRASSIA.** An extensive genus of tropical American Orchids, very nearly related to *Oncidium*, from which they are easily known in most cases by the lateral sepal being very much longer than the other parts of the flower. Since, however, this is also the case in *Oncidium phymatoclithum* and some others, the distinction fails, and botanists are obliged to combine with long

tail-like sepals, a short earless column, and a pair of vertical plates on the lip. In attempting to define what a *Brassia* is, Lindley enumerates seventeen species and many varieties, all pseudobulbous and bearing flowers more or less yellow, in simple racemes. They are chiefly handsome enough to deserve the gardener's care.

**BRASSICACEÆ.** The Cabbage family, a natural order of Thalamifloral Exogens, to which the name of *Caucaceæ* (which see) is usually given.

**BRASSICA.** A remarkable group of plants, of the order *Cruciferae*. As constituted by Bentham, and characterised by its conduplicate cotyledons, and its silique beaked pods, this genus is made to include the mustards (*Sinapis*), an allocation to which we incline, both from experiment and observation. We shall, however, confine our remarks to the genus as constituted by Linnaeus, of which the following are species:—*B. oleracea*, Wild Cabbage; *B. campestris*, Wild Nave, including *B. Rapa*, the Turnip; *B. Adonis*, Rape or Coleseed. Of these, the first is in all probability the initiative. It occurs wild on rocks and cliffs by the sea shore; and we have now in cultivation some curious examples, derived from seed gathered from the rocky coast of Llandudno, North Wales, which already give indications of sports in several directions. Some have the short petioles and the close hearting condition of Cabbages of which form we have both green and red varieties, the tendency being much increased by repeated transplantation. Others, with longer petioles and lyrate leaves, seem to take on that looser method of growth which constitutes the 'Greens' and Kale of the garden; whilst some present that peculiar glaucous hue which belongs more particularly to Rape. We should not, therefore, be surprised if experiment should ultimately establish the position that the *B. oleracea* is the only true species of the three above enumerated, and that the *B. campestris* and *B. Napa* are but agrarian forms derived from the cultivated varieties of this. This opinion is countenanced by the fact that nowhere are the two latter truly wild, but both track cultivation throughout Europe, Asia, and America. The protean forms induced from the *B. oleracea* are well known, such as many varieties—which are yearly increasing—of Cabbage, Broccoli, Cauliflower, Kale, and Kohl-rabi; whilst the no less numerous varieties of the common Turnip are all referred to *B. campestris*, with which, indeed, Bentham classes *B. Napa*.

As regards the Swedish Turnip, we are in the position to state that the seeding of Rye and common Turnips in mixed rows has resulted in the production of a small percentage of malformed Swedes, which, however, improved very much by careful cultivation; and our field observations have enabled us to detect in degenerate

Swedes a disposition to a negation of bulbs, and the production of monstrous rape plants—a tendency which is at once observable when this crop assumes a necky top, or many heads, which shows an inclination to 'run,' or when it forms a branchy finger-and-toe root growth, which indicates a breaking up of the bulb into ordinary roots. It may be remarked, as throwing some light on the nature of the changes by which the cultivated varieties of this genus have been attained, that experiments with seeds of plants showing any particular tendency, and especially if repeatedly grown in the same soil, will ever result in an increase of the peculiarity. [J. B.]

This genus comprises some of the most ancient and useful of our culinary vegetables, most of them possessing high antiscorbutic powers, which are believed to depend upon a certain acrid volatile oily principle—the chemical nature of which is imperfectly known. In common with the rest of the cruciferous order, they also possess a greater share of azote than any other tribe of plants, as is apparent in their fetid smell when fermented.

The Cabbage, *B. oleracea*, in its wild state, is a native of various parts of Europe, as well as of several places near the sea in England. It is a biennial, with fleshy lobed leaves, undulated at the margin, and covered with bloom; altogether, so different in form and appearance from the Cabbage of our gardens, that few would believe it could possibly have been the parent of so varied a progeny as are comprised in the Savoy, Brussels Sprouts, Cauliflower, Broccoli, and their varieties. A more wonderful instance of a species producing so many distinct forms of vegetation for the use of man is scarcely to be met with throughout the range of the vegetable kingdom.

The Common or cultivated Cabbage, *B. oleracea capitata*, is well known, and from a very early period has been a favourite culinary vegetable, in almost daily use throughout the civilized world. The ancients considered it light of digestion, when properly dressed, and very wholesome if moderately eaten. For the introduction of our garden variety of Cabbage, we are indebted to the Romans, who are also believed to have disseminated it in other countries. It is said to have been scarcely known in Scotland until the time of the Commonwealth, when it was carried there from England by some of Cromwell's soldiers; but it now holds a prominent place in every garden throughout the United Kingdom. In general, cabbages are preferred when of a large size, thoroughly hearted and blanched within; they are not, however, then by any means so digestible and wholesome as when cut and eaten in a young state—that is to say, before the heart has become firm and hard. It is a remarkable fact, that all the varieties are sweeter and better flavoured after being touched with frost.

In Germany, salted cabbage, or sauer kraut, is much esteemed, and forms a kind

of food, of which large quantities are prepared for winter use. It is made by cutting the cabbages into small shreds, and afterwards packing them in barrels, in layers three or four inches thick. Over each layer is thrown a certain quantity of salt and unground pepper, with a few cloves; and the whole is then well mixed, and pressed as hard as possible. Other layers are put in, and treated in the same way, until the barrel is full. A board is then placed on the top, on which heavy weights are put, and in this state it remains for ten or fifteen days, when it partially ferments, and a great deal of water rises to the surface. It is then placed in the cellar, and continues in excellent condition for use until late in the spring.

The Red Cabbage, *B. oleracea rubra*, is a very distinct variety, remarkable for the peculiar purple, or brownish-red colour of its leaves. It is chiefly used for preserving as a pickle, for which purpose it is greatly esteemed, and by proper management makes one of the most beautiful pickles that can be presented at table.

The Borecole, *B. oleracea acephala*, has every appearance of being one of the early removes from the original species. It is distinguished from the other sorts of cabbages by its leaves being beautifully cut and curled, of a green or purple colour, or variegated with red, green, and yellow, never closing, so as to form a head, nor producing eatable parts like the Cauliflower. Several sub-varieties of Borecole are well known under the names of German Greens, Buda Kale, Scotch Curlies, or Kale—all of which are so hardy as to be able to endure severe frost, and continue green and fresh throughout the winter. The part which is used is the crown, or centre of the plant, cut so as to include the young and most succulent leaves. When properly dressed, they are tender, sweet, and delicate, more particularly after being exposed to frost.

The Large-ribbed Cabbage, or Couve Tronchuda, *B. oleracea costata*, is a variety peculiar to Trauxada, in Portugal, from whence it was introduced in 1821. It represents a singular race of the cabbage family, and is characterised by its leaves having very large midribs, which, when divested of their green parts, and thoroughly boiled, make an excellent vegetable for serving up in the manner of sea-kale. The heart, or middle part of the plant, has likewise been found very delicate, tender, and agreeably flavoured.

The Savoy Cabbage, *B. oleracea bullata*, differs but little from the other kinds of heading or hearting cabbages, and is chiefly distinguished by its leaves being wrinkled in such a manner as to have a netted appearance. It has been cultivated in our gardens for three centuries. When fully headed, it forms an excellent hardy winter vegetable, for using in the same way as other cabbages, but it is not so delicately flavoured.

The Brussels Sprouts, or Bud-bearing Cabbage, *B. oleracea bullata minor*, origi-

nated in Belgium, and has been cultivated around Brussels from time immemorial; although it is only within the last twenty years that it has become generally known in this country. It is very hardy, and forms a head somewhat like a savoy, of which it is considered to be a sub-variety, differing in the remarkable manner in which it produces at the axils of the leaves, along the whole length of its stem, a number of small sprouts, resembling miniature cabbages, of one or two inches in diameter. These are peculiarly well-flavoured, and, as a winter vegetable, are more highly esteemed than any other kind of cabbage in cultivation.

The Cauliflower, *B. oleracea botrytis cauliflora*, is of great antiquity, but its origin is unknown, although it has been usually ascribed to Italy. It is mentioned by Gerard, and must therefore have been in this country previous to 1597. It differs in a remarkable manner from all the other varieties of the cabbage tribe, whose leaves and stalks are alone used for culinary purposes. Instead of these being taken, the flower-buds and fleshy flower-stalks form themselves in a close firm cluster or head, varying from four to eight inches or more in diameter, and become one of the greatest of vegetable delicacies. It is not valued so much for its large size, as for its fine creamy white colour, its compactness, and regular form, without being warty, which features constitute the properties of a fine Cauliflower. The uses of Cauliflower are well known. When dressed it is served up at table, either plain boiled, or with white sauce. It forms an excellent addition to vegetable soups, and is often used for pickling. It may also be preserved for a considerable time, when pickled like sauer kraut.

The Broccoli, *B. oleracea botrytis asparagoides*, is similar in form and appearance to the cauliflower, from which it is supposed to have originated. It was first brought into notice at the beginning of the last century. Two kinds, the white and purple, are mentioned by Miller (1724) as coming from Italy, and from these have arisen all the varieties that are now in cultivation. Broccoli is more robust and far more hardy than cauliflower, for which it becomes a valuable substitute during the winter and spring months, when the latter cannot be obtained. The heads vary in colour, from a brownish purple to a pure creamy white, in which state they are scarcely to be distinguished from cauliflowers. They are used for the same purposes, but are not so delicate in flavour.

The Turnip, *B. Rapa depressa*, is a hardy biennial, and, in its wild state, is found in corn fields in various parts of England. The change it has undergone by cultivation is no less remarkable than that of the Cabbage; but in this instance it is the root which has been transformed from a comparatively hard woody substance into the large fleshy bulb, which constitutes one of our most nutritious vegetables. The ancient Greeks and Romans were well

acquainted with the Turnip; and, in the fifteenth century, we find it had become known to the Flemings, and formed one of their principal crops. The first Turnips that were introduced into this country are believed to have come from Holland in 1550; and, among all the varieties now cultivated for culinary purposes, the Early Dutch continues to be generally esteemed. The Turnip forms an ingredient in broths, soups, and stews; it is likewise cut into various figures for garnishing. In spring, when the plant is pushing up for flower, the points of the shoots are dressed as greens, and are acknowledged to be valuable as an antiscorbutic.

Rape, *B. Napus*, is a hardy biennial, indigenous to Britain. It is chiefly grown for cutting when quite young, and mixing with mustard, as a small salad. It is also sometimes cultivated in cottage gardens, for spring greens—the tops being cut first, and afterwards the side shoots. The Teltow Turnip, or Navet de Berlin petit' of the French (*B. Napus var.*), is very different from any of our cultivated varieties of Turnip, its root being long and spindle-shaped, somewhat resembling a carrot. Its culture in this country dates from 1700; but it was well known in 1671, and is noticed by Caspar Bauhin in his *Pinnax*. It is much more delicate in flavour than our Common Turnip. In France and Germany it is extensively cultivated, and few great dinners are served up without it in one shape or other. It enriches all soups by the peculiar flavour contained in the outer rind, which is thin, and must not be cut away, but scraped. Stewed in gravy, it forms a most excellent dish, and, being white, is very ornamental when mixed and served with carrots. [W. B. B.]

**BRAVAISIA.** The *Oncocanthus Cunninghamii* of Nees von Esenbeck. [B. S.]

**BRAVOA.** A genus of Amaryllidæ, containing a single species, *B. gemmiflora*, native of Mexico. This is a bulbous or rather a tuberous plant, with a tuft of radical linear keeled leaves, and an erect flower-stem, a foot or more in height, supporting a raceme of nodding flowers, which grow in pairs, and are of a rich orange-red outside and yellowish within. The tuber is somewhat elongated, tunicated, sending down several thick fleshy roots. The perianth, which is rather over an inch long, consists of a funnel-shaped curved tube widening at the throat, and having a very short six-lobed somewhat spreading limb. There are six stamens, and an inferior three-lobed ovary, with a long exserted filiform style terminated by a dilated stigma. It is a very graceful plant. [T. M.]

**BRAYERA.** A genus of *Rosacææ* named after a French physician, Dr. Brayer, who observed the valuable medicinal properties of the only species of this genus, and sent a specimen of the plant to Kunth. The plant is known by its top-shaped calyx, the limb of which is divided into ten

segments, five exterior to the remainder, which are much smaller and of a different shape; it has two small bracts at the base. Petals five, small, linear, scale like; stamens fifteen to twenty, inserted with the petals into the throat of the calyx, the filaments unequal in length. Carpels two at the bottom of the calyx, one to two-seeded; style terminal; stigma peltate.

*D. anthelmintica*, the only known species, is an Abyssinian tree with alternate pinnated leaves and drooping flowers; in the true female flowers the petals and stamens

*Bryonia anthelmintica*.

are entirely wanting. The flowers of this tree have been long used by the natives as a vermifuge, and have proved very efficacious in the removal of tape-worm in this country. The cause of its peculiar effects is not well understood. [M. T. M.]

**BRATETTE.** (Fr.) *Primula (officinalis) veris*.

**BRAZILETTO.** The common name for *Cesalpinia*; also specially, the colonial name of *C. brasiliensis*, the timber of which is used for cabinet-work.

**BRAZIL WOOD.** A dye wood obtained from *Cesalpinia echinata*, and other species.

**BRAZORIA.** A genus of *Labiata*, native of Texas, and containing two species of erect branching herbs, with the lower leaves petiolate and obovate-oblong, the upper serrate and lanceolate, and the flowers in singly terminal spikes. The calyx is campanulate and two-lipped, with the upper lip bilobed and the lower trilobed. The corolla tube is considerably exserted, the throat inflated, and the limb bilabiate, with the upper lip erect, slightly bilobed or entire, and the lower deeply trifid, with its roundish lobes spreading or recurved. [W. G.]

**BREAD-FRUIT.** *Artocarpus incana*.

**BREAD-FRUIT TREE** of North Australia. *Gardenia edulis*.

**BREAD-NUT.** The seed of *Diosimum Allicastrum*.

**BREAD-ROOT.** *Psoralea esculenta*.

**BREAD, NATIVE,** of Australia. *Mythen australis* —, **TARTAR.** The fleshy root of *Cranibe tatarica*.

**BREAK-AXE,** of West Indies. *Sloanea jamaicensis*.

**BREAK-YOUR SPECTACLES.** A translation of the French name—*Casse lunettes*—for *Centaurea Cyanus*.

**BREATHING-PORES.** See Stomata.

**BREDEMEYER.** A genus of *Polygonaceae*, comprising ten species, natives of Tropical America. They are suberect or often scandent shrubs, with alternate ovate or oblong pinnerved leaves, and numerous yellow flowers arranged in terminal panicles. Sepals five, unequal, the two inner petaloid; petals three, the central one keeled; stamens eight, united below; ovary bicellular; fruit, a drupe. The genus as now defined includes *CATOCOMA*, which see. [J. Br.]

**BREDES.** (Fr.) *Solanum nigrum*, — **D'ANGOLE.** *Baccharis rubra*, — **GLACIALE.** *Meembryanthemum crystallinum*.

**BREHMIA.** A genus of *Loganiaceae*, containing but one species, *B. spinosa*, which is, as its name implies, a spiny shrub. It grows about ten feet high, and is furnished with opposite stalked three or five-nerved entire leaves, elliptical in form, and small green flowers arranged in dense cymes at the apex of the branches. The hard-shelled ripe fruit resembles an orange in size and appearance, and contains many seeds immersed in a copious pulp. The genus differs chiefly from the *nux-vomica* (*Strychnos*) in having a one-celled ovary. The plant is found in Madagascar, where it is called 'Volva Vountaca', in eastern Africa, and also on the west coast. The pulp of the fruit is commonly eaten by the natives wherever it grows; it is somewhat acid, and said to be delicious; but probably the seeds, from its near relationship to the *nux-vomica*, are poisonous. It is, however, remarkable that the pulp of many species of *Strychnos*, whose seeds are a deadly poison, is perfectly harmless. [A. A. B.]

**BREJEUBA.** A kind of Cocoa-nut, the wood of which is used by the Brazilian Indians in making their best bows.

**BRE'SINE.** (Fr.) *Zinnia multiflora*.

**BREWERIA.** A genus of herbs or undershrubs, natives of New Holland, tropical Asia, and Madagascar, belonging to the order *Convolvulaceae*. They have alternate entire leaves, and solitary axillary flowers. The calyx consists of five sub-equal sepals; the corolla is campanulate and plaited. There are five included stamens. The ovary is two-celled, with two ovules in each cell, and bearing a

style which is divided nearly half its length, and has a capitate stigma on each division. The capsule is two-celled and contains four seeds. [W. C.]

**BREXIA.** A genus of small trees formerly referred to *Breziaceae*, an order now merged in *Saxifragaceae*. They are natives of Madagascar, and have alternate petiolate leathery leaves, entire or furnished with spiny teeth. The flowers are in axillary umbels, of leathery texture and greenish hue; calyx with five short segments; petals also five; stamens five, arising from a toothed disk surrounding the base of the ovary, and adnate with it; ovary five-celled. Fruit drupaceous, five-ribbed, slightly papillose, about the size of an orange; seeds numerous. [J. T. S.]

**BREXICEAE.** The genera *Brexia*, *Izberba*, *Argophyllum*, and *Roussaea*, each consisting of only one or two species, have been proposed as a small family allied to *Saxifragaceae*. They are, however, not all very closely connected with each other, and neither form a natural group, nor are they united by any well-marked common character; and in the recent *Genera Plantarum* of Benth and Hooker, they are, together with several other small orders, included in the *Saxifragaceae*. The orders thus associated with *Breziaceae* under *Saxifragaceae*, are the *Aculloniaceae*, *Hydrangeaceae*, *Cunoniaceae*, *Roussaceae*, *Prunaceae*, *Grossulariaceae*, and *Phyllodaphneae*. The genera above named are, in the work above alluded to, all included in the tribe *Aculloniaceae*. [T. M.]

**BRIDGERIA.** A genus of the Soapwort family (*Sapindaceae*), indigenous to the province of Coquimbo in Chili. The cut-leaved *B. incisiifolia* is the only known species, and is a shrub three to five feet high with alternate stalked simple lobed leaves, and with the flower-stalks axillary and single, some of the flowers, which are small, bearing stamens only, others with both stamens and pistil. The fruit is a three-celled bladder capsule, each of the cells prolonged into a wing on the back, and containing a single seed. The genus may be distinguished from any in the family by its leaves alone. It bears the name of Mr. Bridges, a most extensive collector of Chilean plants. The same name has been also given to a group of *Phytolaccaceae*, now included in *Evolvaceae*; and to a group of *Compositae*, now included in *Folyschymus*. [A. A. B.]

**BRIER, or BRIER ROSE.** The common larger-growing British species of Rose, especially the Dog Rose, *Rosa canina*; sometimes written Briar. — **SWEET.** The Eglantine, *Rosa rubiginosa*.

**BRIGALOW.** *Acacia eccelsa*.

**BRIGNOLES.** The dried fruits known as Provence prunes or French plums.

**BRILLANTaisia.** A genus of *Aconitaceae*, containing one or two species, natives of Guinea. They are erect branching herbs with ovate-cordate leaves on long petioles, and large purple flowers in

terminal panicles, with small linear bracts. The calyx is five-parted, with unequal linear segments, the upper being the longer. The ringent corolla has the upper lip bilobate and overarching with a trifid apex, and the inferior large, spreading, and shortly trifid. There are two fertile stamens inserted at the top of the tube, and having long linear bilocular anthers; the two barren stamens are represented by short filaments. The ovary is oblong, hairy, and surrounded by a disc, and bears a style of the same length as the corolla, terminated by an unequally bifid stigma. The capsular fruit is straight, narrow, tetragonous, and two-celled, with six to eight seeds in each cell. [W. C.]

**BRIMSTONE, VEGETABLE.** The inflammable spores of *Lycopodium clavatum* and *Selago*, employed on the continent in the manufacture of fireworks.

**BRINJAL.** The fruit of the egg-plant, *Solanum Melongena*. Mr. Benth writes it Brinall.

**BRINVILLIERS.** (Fr.) *Spigelia Anthelmia*.

**BRISTLEWORTS.** A name applied by Lindley to the *Desfontainiaceae*.

**BRISTLY.** Covered with stiff sharp hairs, or bristles.

**BRITTLEWORTS.** A name given by Lindley to the *Diatomaceae*.

**BRIZA.** A genus of Grasses belonging to the tribe *Festuceae*, distinguished chiefly by the inflorescence being in panicles, the spikelets of which contain from five to twelve imbricated flowers; and in the two glumes being nearly equal, and like the pales membranous, with scarious margins. The Quaking Grasses are all handsome plants, so much so, that *B. maxima* and *B. minor* are frequently cultivated in gardens as ornamental annuals. Stourel describes thirty species, which are mostly natives of South America: Brazil, Chili, and Peru, being the principal countries which produce them. Two are British plants, *B. media* and *B. minor*; the former a very common species, on light limestone soils, &c., the latter confined to a few localities in England. They are not of agricultural importance, though *B. media* is a prevailing grass on some good permanent pastures. [D. M.]

**BRIZOPYRUM.** A genus of Grasses belonging to the tribe *Festuceae*. Eleven species are described, which are mostly natives of the Southern Hemisphere. One is, however, from Nootka Sound, *B. boreale*, and another curious species found by Drummond in Australia, *B. setipoides*, has leafless culms rising to the height of four feet. [D. M.]

**BROAD SEED.** The common name for *Uloperma*.

**BROCCOLI.** A cultivated variety of the Cabbage, *Brassica oleracea*, in which the

young inflorescence is condensed into a depressed fleshy edible head.

**BRODIAEA.** A small genus of *Liliaceae*, consisting of bulbous plants from Western North America, with linear leaves and naked scales terminated by an umbel of rather large blue flowers. The base of the umbel is surrounded by an involucre of small scarious bracts; perianth funnel-shaped, six-cleft; stamens three, attached to the perianth, alternating with three scales (abortive stamens). The ovary is surrounded by a fleshy three-lobed hypogynous disk. The bulbs are small, enveloped in a dark rough coat. [J. T. S.]

**BROKEN**, when applied to a whorl, signifies that the parts thereof are not all on the same plane. In fact, they form a part of an extremely short spiral, as may be seen in the calyx of any species of *Hypericum*.

**BROME, FALSE.** A common name for *Brachypodium*.

**BROMELIACEÆ** (*Bromeliæ*, *Tillandsiæ*, *Bromelads*, *Bromelworts*, the *Pine-Apple* family). A natural order of Epigynous Monocotyledons included in Lindley's *Narcissal* alliance. Short-stemmed plants with rigid channelled often scurfy and spiny leaves, and showy flowers. Outer perianth (calyx) three-parted, persistent; inner (corolla) of three withering petals; stamens six, inserted in the tube of the perianth; anthers opening on the side next the pistil; style single. Fruit either a dry capsule or succulent, three-celled, many-seeded; embryo very small, at the base of mealy albumen. Natives of the American continent and islands, whence they have been distributed to Africa and the East Indies. *Ananassa sativa*, the Pine apple or Ananas, is one of the most important plants of the order. Its fruit is composed of the pistils and bracts of several flowers united into a succulent mass and crowned by a series of green leaves. It is *par excellence* the fruit of the Eastern Islands. The fibres of the plant are used in manufacture. *Bromelia Pinguin* is a remedy for worms in the West Indies. Some of the Bromeliads grow attached to the branches of trees, and are called Air-plants. One of these is *Tillandsia usneoides*, the Tree-beard of South America, which consists of a mass of black fibres. These are employed for stuffing cushions, under the name of Spanish Moss, Black Moss, or Long Moss. There are twenty-eight known genera and 176 species. Illustrative genera: *Ananassa*, *Bromelia*, *Bechmea*, *Bilbergia*, *Tillandsia*, *Bonapartea*. [J. H. B.]

**BROMELIA.** The natural order *Bromeliaceæ* takes its name from this genus, which consists of plants with short stems, and densely-packed rigid leaves, generally lance-shaped, with spiny margins, and channelled on the upper surface. The calyx is three-parted, much shorter than the corolla, which consists of three petals, convolute, erect or spreading at the top.

The stigmas are three—short, fleshy, and erect. The fruit is succulent. The fruit of *B. Pinguin* yields in the West Indies a cooling juice, much used in fevers, etc. Many of them supply valuable fibre for textile purposes, and which might also be employed in the manufacture of paper. Several species are cultivated in stoves for their ornamental flowers. [M. T. M.]

**BROMHEADIA palustris.** In the Malay Archipelago there grows in bogs the Orchidaceous plant to which this name has been given. It has the habit of such New World species as *Epidendrum elongatum*, the stems being erect, and clothed with leathery distichous leaves. The flowers, which are large and white, with a purple and yellow lip, are placed close together on a stiff zigzag rachis, which is in some cases branched. The lip, which is cucullate, and firmly fixed so as to be parallel with the column, has the unusual character of bearing a long woolly ridge in the middle. Mr. Finlayson first detected it near Singapore.

**BROMUS.** A genus of grasses, belonging to the tribe *Festuceæ*, distinguished chiefly by the inflorescence being in lax panicles, very rarely crowded; glumes unequal, containing from three to many flowers, the spikelets lanceolate and compressed; florets two, the lower with a long awn attached nearly at the tip; styles below the top of the fruit. Steudel describes 141 species in his *Synopsis*. They have a very extensive geographical range. The greater number are, however, natives of temperate climates, and those that approach tropical limits generally grow at considerable elevations on mountains. About eight species are natives of Britain, along with some which have been introduced, and are now enumerated in British floras. They are not considered first-class agricultural grasses, though the Soft Brome Grass, *B. mollis*, constitutes a large portion frequently of good meadows, but being of annual duration only, it is not so common on good permanent pastures. [The *B. Schraderi*, known as the Australian Prairie Grass, is, however, likely to prove a valuable forage plant, being remarkable for rapidity of growth and productiveness. It is also said to be valuable for sowing in coverts, as it entices hares and rabbits into the woods away from the grain crops. See *CERATOCLOA*.] [D. M.]

**BROMELIARTIA.** A genus of the Pea-flowered tribe of the Leguminous family, numbering eight species, all of them natives of Mexico or Texas. They are shrubs, with unequally pinnate leaves, and many pairs of ovate or elliptical leaflets, which are generally about half-an-inch in length. The flower-stalks are twin, in the axils of the upper leaves, and the flowers flesh-coloured, or violet, the keeled petal yellow. The pods are stalked, thin, and in form like the blade of a table knife, but pointed, and contain six to eight seeds. None of the species are in cultivation. The genus is named in honour of Adolphe Brongniart, a famous French botanist. [A. A. B.]

**BRONTESIS.** A name given to express the injury done to plants by lightning. This is generally clear enough from the outward effects, the branches being broken, and the trunk shivered. The injury, however, may be more insidious, and, though no external damage may appear, or none which immediately excites attention, the connection of the component parts of the trunk may be dissolved more or less completely, by the sudden generation of gas, or the expansion of the sap, from the intense heat of the lightning. The whole vegetative power of a tree may also be at once arrested. But many of the cases of sudden death which are commonly attributed to lightning are the results of the spawn of some fungus attacking the roots, vegetation being kept up by a slight thread of sound tissue, as in the condition called gumming; and when this at last gives way, the plant at once perishes. [M. J. B.]

**BROOK-BEAN.** *Menyanthes trifoliata*.

**BROOKLIME.** *Veronica Beccabunga*.

**BROOKWEED.** *Samolus*.

**BROOM.** *Cytisus*, or *Sarothamnus scoparius*; also applied to *Lygeum Spartium*.

—, **AFRICAN.** A common name for *Apalathus*. —, **DYER'S.** *Gentiana tinctoria*.

—, **NEW ZEALAND.** *Carmichaelia australis*.

—, **RUSH.** A common name for *Pimmaria*; also applied to *Spartium junceum*.

—, **SPANISH.** *Spartium junceum*.

**BROOM CORN.** *Sorghum vulgare*, the branched panicles of which are made into carpet brooms and clothes-brushes. Also *Sorghum saccharatum*.

**BROOMEIA.** A most remarkable genus of Puffballs, which has at present occurred only in South Africa. The inner sac, or peridium, is precisely like that of *Gaster*, but completely exposed, the outer sac being represented by a thick corky stratum, in which a multitude of individuals are half sunk, like jewels in a matrix. Some approach to it is made by a fine compound species of starry puffball, found in Ceylon and Cuba, though in that case the inner peridium is not at all exposed. [M. J. B.]

**BROOM RAPE.** The common name for *Orobancha*. —, **NAKED.** An American name for *Aphyllon*.

**BROSIMUM.** A genus of the order of artocarpads (*Artocarpaceae*), containing six or seven species, natives of tropical South America. They are large trees, abounding in milky juice, and having entire leaves. Their male and female flowers are generally congregated into a globular head, but are sometimes borne on separate trees; they have neither calyx nor corolla, the males consisting of single stamens, separated from each other by shield-like scales, and the females of a solitary style, terminating in two stigmas. The fruit is a small one-seeded berry.

*B. Allicastrum*, the Bread-nut tree of Jamaica, has a tall straight trunk, and

smooth shining deep-green elliptical lance-shaped leaves. Its pale-yellow heads of flowers are succeeded by round yellow fruits, about an inch in diameter, and containing a single seed, called Bread-nut in Jamaica. These so-called nuts are eatable, and are said to form an agreeable and nourishing article of food: when boiled or roasted, they taste like hazel-nuts. The young branches and shoots, also, are an excellent fodder for horses and cattle; and the wood, which bears some resemblance to mahogany, is used by West Indian cabinet-makers.

*B. Aubletii*, a native of British Guiana and Trinidad, also forms a large tree, often sixty or seventy feet high, and two or three feet thick. The leaves are of an oblong form, with their top end broader than the bottom; and they are covered with a whitish down on the under surface. The heart wood of this tree is exceedingly beautiful, being of a rich brown colour, and mottled with irregularly-shaped dark spots, on which account it is called Letter-wood, Snake-wood, or Leopard-wood. Unfortunately, however, it is only procurable in narrow pieces, and is therefore chiefly used for veneering small articles of furniture, and for making walking-sticks, which, however, are very liable to split.

*B. Galatodendron*, which is the Cow-tree of South America, yields a milk of as good quality as that from the cow. It forms large forests on the mountains near the town of Cariaco, and elsewhere along the sea-coast of Venezuela—growing to upwards of 100 feet high, with a smooth trunk six or eight feet in diameter, and without branches for the first sixty or seventy feet of its height. The leaves are of a leathery texture, strongly veined, and of a deep shining green colour. They are about a foot long, and three or four inches broad, of a somewhat elliptical form, terminating in a sharp point. In South America the Cow-tree is called Palo de Vaca, or Arbol de Leche. Its milk, which is obtained by making incisions in the trunk, so closely resembles the milk of the cow, both in appearance and quality, that it is commonly used as an article of food by the inhabitants of the places where the tree is abundant. Unlike many other vegetable milks, it is perfectly wholesome, and very nourishing, possessing an agreeable taste, like that of sweet cream, and a pleasant balsamic odour; its only unpleasant quality being a slight amount of stickiness. The chemical analysis of this milk has shown it to possess a composition closely resembling some animal substances; and, like animal milk, it quickly forms a yellow cheesy scum upon its surface, and, after a few days' exposure to the atmosphere, turns sour and putrifies. It contains upwards of thirty per cent. of a resinous substance, called galactin by chemists. [A. B.]

**BROSSEA.** An imperfectly known genus of *Vacciniaceae*, comprising a West Indian shrub, bearing solitary axillary or a

few terminal flowers, whose stalks have two bracts, a conoid corolla, five included stamens. The capsule has five many-seeded compartments, and is covered by the enlarged limb of the calyx; seeds very small. *B. coccinea* is in cultivation, and is described as a cistus-like shrub, with scarlet flowers half an inch long. [M. T. M.]

**BROUALLE R'LEVE'E.** (Fr.) *Browallia elata*.

**BROUGHTONIA** *sanguinea* is a handsome West Indian epiphyllal pseudobulbous Orchid with oblong coriaceous leaves, and a short spike of deep crimson flowers. It has a spur completely immersed beneath the surface of the ovary. It is common in Cuba on bushes, but more usually comes from Jamaica. Its nearest affinity is with *Leilia* and *Cattleya*.

**BROUSSONETIA.** This genus is allied to the Mulberry, and belongs to the same order of Morads (*Moraceæ*). Three species have been defined, but they may probably be all referred to one, namely, *B. papyrifera*, the Paper Mulberry, which is so called on account of its fibrous inner-bark being used by the Japanese and Chinese for making paper. It grows wild in China and Japan, and also in many of the islands of the Pacific Ocean, where the natives manufacture a large part of their clothing from its bark. It forms a small tree, attaining about twenty or thirty feet high, with a trunk seldom more than a foot in diameter, and generally branching at a short distance from the ground. The young branches are covered with short soft hairs. The leaves are deciduous, and vary very much in shape, those of young trees being frequently divided into three or five sharp-pointed irregular lobes, while those of older trees are mostly entire and of a somewhat egg-shaped outline; they are very rough upon the upper surface, and slightly hairy beneath. It has distinct male and female flowers produced upon separate trees; the males being in cylindrical drooping catkins, each flower growing from the base of a small bract, and having a four-parted calyx and four stamens; while the females are congregated into round heads or balls about the size of marbles, and each have a tubular three or four-toothed calyx, a single style produced from the side of the ovary, and a tapering stigma. They are succeeded by deep-scarlet pulpy fruits, resembling a mulberry in structure, and of a sweetish flavour, but rather insipid.

The Japanese cultivate this plant very much in the same way that we grow osiers, and they use only the young shoots for the manufacture of paper; these are cut into conveniently sized pieces, and boiled until the bark separates readily from the wood, when it is peeled off and dried for future use. To convert this bark into paper, they proceed in the following manner:—The dried bark is first moistened by soaking for a few hours in water; all superfluous matter is then removed by scraping with a

knife, after which the bark is boiled in a ley of wood-ashes until its fibres are thoroughly separated, when it is reduced to a pulp by beating with wooden batons; this pulp is then mixed with mucilage and spread upon frames made of rushes. The paper thus made is of a whitish-brown colour, and very strong; it is in common use in Japan. Instead of paper, the natives of the South Sea Islands manufacture from this bark an exceedingly tough cloth, called *tapa* or *kapa* cloth, which they commonly use for clothing, either plain or printed, and dyed of various colours. This cloth is principally made by the women, who adopt the following method of manufacture:—The bark is first softened by being soaked in water for a considerable length of time: it is then placed upon a log of wood and beaten out with a baton

*Broussonetia papyrifera*.

until it is of the requisite degree of fineness: the baton is made of very hard wood, and has four flat sides, each of which is sharply ribbed. Two or four women usually work together, and as they keep time in beating, the noise they make is loud and musical. In some islands, however, another and inferior method is adopted, the bark being placed upon a flat board, and scraped with different kinds of sharp-edged shells while kept constantly wet. By employing mucilage obtained from the arrow-root, the natives join pieces of the cloth together, and Admiral Sir Everard Home states that the King of Tongataboo (one of the Friendly Islands) had a piece made which was two miles long and 120 feet wide.

[A. S.]

**BROWALLIA.** The name of certain plants belonging to the order of Linariads, characterised thus: calyx-teeth unequal; corolla silver-shaped with a border divided into five parts, all of a roundish outline and slightly notched at the tip, one piece broader than the others; end of the style or appendage of the seed-vessel four-lobed. The genus was named by Linnaeus in honour of John Browallius, bishop of Abo, who strenuously supported

the system of that great botanist. The plants of this genus are natives of tropical America, usually of erect habit, smooth, or hairy and viscid; the leaves alternate, stalked, ovate in outline; the flowers violet or blue, more rarely white. Their handsome flowers and easy cultivation render them favourite objects of culture. *B. elata*, an upright-growing species, and *B. demissa*, of more spreading habit, have been long in cultivation; the latter is a native of Panama, and has the leaves oblong-ovate, oblique at the base, the branches and flower-stalks downy, the corolla pure pale blue, tending to purple or red: sometimes all three colours are associated on the same plant. [G. D.]

**BROWNEA.** A genus of small evergreen trees belonging to the *Leguminosae* and to that section having regular corollas. The species are peculiar to Venezuela, New Grenada, and some portions of central America, one of them being also found in Trinidad. The leaves are alternate, equally pinnate, and from one to one and a-half foot long, with from four to twelve pairs of entire leaflets. The flowers are rose-coloured or crimson, and disposed in dense terminal or axillary sessile heads. The pods are compressed scimitar-shaped, often covered with rusty pubescence, and contain many seeds. It would be difficult to point out a more beautiful genus of stove-plants than this, and few tropical plant-houses of any pretensions are without some of them. *B. grandiceps* has long pinnate leaves with about twelve pairs of leaflets and axillary or terminal flower-heads eight inches in diameter; the flowers are pink, very numerous, and arranged in tiers as it were round a conical axis, the outer ones expanding first, followed by the others until all are open, when the flower-head is not unlike that of a *Rhododendron*. The leaves droop during the day so as almost to hide the flowers from view; but they have been seen to rise up in the evening and remain erect all the night; the flowers are thus exposed to the falling dew, but the leaves drooping again during the day, protect the flowers from the heat of the sun. This species is a native of Venezuela, where it is called *Rosa del Monte* or *Palo de Cruz*, and was introduced to England in 1823. Altogether there are six species in cultivation, some of them with bright scarlet flowers, as in *B. coccinea*, which was the first known in our gardens. The genus is named in honour of Patrick Browne, who wrote a history of Jamaica. [A. A. B.]

**BROWNIAN MOTION.** A phenomenon sometimes called molecular motion, which occurs in minute particles, both of vegetable and mineral origin, consisting in a rapid whirling motion, the nature of which is obscure, but is certainly independent of evaporation or other appreciable external causes which produce motion in minute bodies. It may be seen admirably in a weak solution of gamboge, with a

power of 250 linear. It is frequently observed in the minute anatomy of vegetables, especially when the tissues are diseased. [M. J. B.]

**BROWNLOWIA.** A genus of the Lime-tree family. *B. elata*, a native of Chittagong in Burmah, is the best known species, and attains a great size, full-grown trees being about fifteen feet in circumference at four feet from the ground; the branches are numerous and spreading, forming a large ovate shade; head, and the leaves, like those of the lime-tree in form, are entire, five to seven-nerved, and often a foot in length and eight inches broad. The flowers are in terminal panicles, very numerous and showy, white or pale yellow in colour. The fruit is made up of five baccate carpels, each containing one seed. [A. A. B.]

**BROWN RED.** Dull red, with a slight mixture of brown.

**BRUCEA.** A genus of *Simarubaceae*, so called in honour of the famous Abyssinian traveller. It consists of shrubs with compound leaves; flowers in heads, unisexual or sometimes hermaphrodite; parts of the flower in fours; stamens attached to a central gland-like four-lobed gynophore or stalk supporting the four drupes. The stamens are sterile in the female flowers. The species are natives of Abyssinia, China, &c., and some of them possess bitter properties similar to quassia, a drug furnished by a tree of the same natural order. [M. T. M.]

**BRUEA.** A genus of *Artocarpaceae*, comprising a shrub with alternate somewhat heart-shaped serrated woolly leaves, and having leafy bracts, and terminal stalked diœcious flowers. Calyx tubular, irregularly four-toothed; ovary oblique; stigma lateral, sessile, very long, fringed; fruit hairy. Native of Bengal. [M. T. M.]

**BRUGMANSIA.** The name of a genus of *Solanaceae*, or of one which was formerly included in that order, but which has been separated by Miers, under the name *Atropaceae*. The species were formerly comprised under the genus *Datura*, as there is a close resemblance in the flowers; but these plants are shrubs, and their fruit is smooth, not spiny, and contains but two cells. *B. suaveolens* is a well-known ornament of our greenhouses, with its large fragrant tubular white blossoms, which are sometimes produced in great profusion; it is perhaps better known under its old name of *Datura arborea*. Other species with orange and red flowers are in cultivation; and both white and red varieties are common in gardens in India. All are natives of Peru and South America. Their seeds are dangerous stimulating narcotics.

The name *Brugmansia* is also applied to a genus of plants parasitical, in Java, on the roots of certain species of *Cissus*. They consist of little else but flowers, which are of the size of the flat, hermaphrodite, with a whitish perianth, which is two or three-

cleft and internally scaly or hairy. These plants are nearly allied to the curious and gigantic *Bufflesias*. [M. T. M.]

**BRUGUEIRA.** One of the genera of the Mangrove family (*Rhizophoraceæ*), and known by having a top-shaped calyx adherent to the ovary below, and having a persistent five to thirteen-lobed limb; five to thirteen oblong petals, cleft into two segments, leathery, woolly at the margin, and so folded that each petal conceals two stamens, whose filaments are not of equal length, but all shorter than the petals opposite which they are placed in pairs; their anthers are linear, or arrow-shaped. The ovary has two to four compartments, each containing two ovules; stigma two or four-toothed on the end of a style, which is about the length of the stamens. The fruit is crowned by the persistent calyx, and the seed within it germinates before it has fallen from the branch, as in the true mangroves. The trees are natives of the East Indies, where the bark is used as an astringent, for tanning purposes, and for dyeing black. [M. T. M.]

**BRUMAILLE.** (Fr.) *Erica scoparia*.

**BRUNELLIA.** A genus of *Xanthorrhoeaceæ*, consisting of trees with simple or compound leaves, and unisexual flowers in axillary or terminal panicles. The calyx is four or five-parted. There are no petals. The eight or ten stamens of the male flowers arise from a depressed hairy disc. In the female flowers the stamens are absent, but there are four or five ovaries, each terminated by a short style. The fruit consists of four or five two-seeded capsules, which open inwardly. The species are natives of tropical America, and the Sandwich Islands. [M. T. M.]

**BRUNFELSIA.** A name given to a genus of *Scrophulariaceæ* in honour of Otto Brunfels of Metz, who lived about the middle of the sixteenth century, and contributed to the revival of botanical science. The genus is known by the possession of a five-cleft calyx; a corolla with a long tube, very slightly dilated at the top, and a flat limb, five-cleft with rounded lobes, bilabiate in maturation; four fertile stamens with anthers which are confluent at the top; and a style which is bent inwards at the top, where it is divided into two stigmatic lobes. The capsule is leathery or fleshy, more rarely indehiscent and drupe-like; seeds several, rather large, imbedded in pulp. The species are shrubs or small trees natives of South America and the West Indies, and have handsome fragrant flowers of blue or white colour. Some of the species are in cultivation. [M. T. M.]

**BRUNIAEÆ.** A small family not separated by any positive character from *Hamamelideæ*, although very different in habit. They are mostly much-branched henth-like shrubs from South Africa or Madagascar. The leaves are usually small, crowded and entire, without stipules. The

flowers in terminal heads, with an inferior or half-inferior one to three-celled ovary, having one to two pendulous ovules in each cell; a five-cleft calyx; five petals alternating with the calyx-lobes; five stamens alternating with the petals; and a simple or two and three-cleft style. The fruit is dry and indehiscent, or separates into indehiscent cocci. There are about sixty species known, distributed into fifteen genera, including *Grubbia* and *Ophira*, of which some botanists form a distinct family, still more nearly allied to *Hamamelideæ* in habit as well as in character. The *Bruniaceæ* will indeed probably hereafter be entirely included in *Hamamelideæ*, notwithstanding their want of stipules, which is now supposed to be the only constant differential character.

**BRUNIA.** A genus of epiphygous Exogenous plants, typical of the group *Bruniaceæ*, distinguished chiefly by having the flowers aggregate in little heads; calyx superior, five-parted; filaments of the stamens inserted into the claws of the petals; stigmas cleft, with small two-celled ovaries. The species are all natives of South Africa, and, consequently, require the protection of a greenhouse in England. *B. nodiflora* is the species which is most generally cultivated, and when well grown, it forms a very handsome plant. [D. M.]

**BRUNNEUS.** Deep brown; not much different from chestnut-brown.

**BRUNNICHIA.** A genus of *Polygonaceæ*, containing a single species, *B. cirrhosa*, a native of the warmer regions of North America. The stem is shrubby, twining, with alternate shortly-stalked smooth ovate-acuminate entire leaves; the leaf-stalks are dilated at the base, and half-clasping, a hairy line completing the circle round the stem; peduncles axillary and terminal often ending in tendrils; bractlets small with several flowers from the axil of each, the whole so arranged that the flowers are racemose on the peduncles; perianth herbaceous, very small, bell-shaped, five-parted; stamens eight or ten; styles three; nut three-angled. [J. T. S.]

**BRUNONIA, BRUNONIAEÆ.** The genus *Brunonia* consists of two Australian herbs with capitate blue flowers, giving them the aspect of a *Scabiosa* or of a *Globularia*; whilst in their structure, and especially in their stigma, enclosed in a two-valved cup, they are more nearly allied to *Goodeniaceæ*. Robert Brown, in whose honour the genus was named, considered it as a section or anomalous genus of the latter family; whilst others have thought that the completely free ovary and exalbuminous seeds, combined with the inflorescence, are sufficient to mark it as a distinct family under the name of *Brunoniaceæ*.

The *Brunonias* grow up with tufts of entire spatulate radical leaves, and naked scapes terminated by the compact head of small blue flowers, which are surrounded by bracts. The five-cleft calyx has three

bracts at the base; the corolla is five-parted, the two upper segments separate from the others; the five stamens are hypogynous, with the anthers slightly cohering; the ovary is free, one-celled and one-ovuled, with a simple style; and the fruit is a membranous utricle enclosed in the hardened tube of the calyx. [J. T. S.]

**BRUNSVIGIA.** A genus of *Amaryllidaceae*, distinguished by broad recumbent hleml leaves, an autumnal precocious flower-scape, a very short-tubed recurved perianth, recurved style and filaments, the filaments not adhering beyond the tube, and a triangularly turbinate capsule. The *Brunsvigias* are rather remarkable bulbous plants of South Africa, closely related to *Amaryllis* itself. The typical species, *B. multiflora*, has a globose bulb as large as an infant's head, and produces distichous obtuse striated linguliform leaves seven or eight inches long, and a fleshy compressed scape, a span or more in height, supporting an umbel of from twenty to sixty purple flowers, which have lance-shaped segments spreading or revolute at the tips. There are but few other species referred to the genus. [T.M.]

**BRUSE.** (Fr.) *Ulex europæus*.

**BRUSH-APPLE.** The native Australian wood of *Achras australis*.

**BRUSH-CHERRY.** The native Australian wood of *Trochocarpa laurina*.

**BRUSH-SHAPED.** See *Aspergilliform*.

**BRUSSELS SPROUTS.** A cultivated variety of the Cabbage, *Brassica oleracea*, having the leaves blistered, and the stems covered by little close heads or hearts.

**BRUYERE.** (Fr.) *Calluna vulgaris*. — **DU CAP.** *Phytica ericoides*.

**BRYACEÆ.** A large group of *Acrocar.* pous Mosses distinguished by the capsules having a double row of teeth, the inner of which are united at the base by a common plicate membrane. Very rarely there is a single row only, or the teeth are obsolete. The capsule is almost always pendulous. The stem is at first simple, but at length branched by means of new shoots, called innovations, given off near the tip, or the base, sometimes from subterranean creeping shoots. The leaves have a central nerve, and consist of large reticulations, and are mostly serrated at the margin and thickened. Very rarely the fruit is lateral as in *Mitchoferia*. Many of the species of *Mnium*, as *M. punctatum*, *rostratum*, *undulatum*, &c., are a great ornament to woods and rocks from their large leaves and handsome capsules, while various species of *Bryum* attract notice on walls, gravel-walks, and marshes, by their tufted habit and abundant pendulous capsules. Amongst these *Bryum argenteum* is peculiarly conspicuous from the silvery white of its leaves. *Bartramia* and one or two closely allied genera are remarkable for their nearly spherical capsules, which are almost all

ways more or less streaked or furrowed, especially when dry. Our more common species, as *Bartramia pomiformis*, are sub-alpine, or occur in bogs. Sometimes the term *Bryaceae* is applied to the whole of the true mosses, as in Lindley's *Vegetable Kingdom*. [M. J. B.]

**BRYA.** A genus of Leguminous plants (*Fabaceae: Papilionaceae*) consisting of three species, small trees or large shrubs, natives of tropical America. They have a five-toothed, somewhat two-lipped calyx; a papilionaceous corolla; and stamens united into a tube, which is split down one side. Their fruit is a flattened two-jointed pod, the upper half of which is generally imperfect, the lower containing a solitary seed. The leaves are solitary, or in clusters, or pinnate.

*B. Ebenus*, the Jamaica or West Indian Ebony-tree, is a large shrub or small tree, growing twenty or thirty or even forty feet high, with a trunk seldom exceeding four inches in diameter; it has long slender tough and flexible branches, which are armed with short sharp spines, and bear numerous small evergreen leaves, resembling those of the common Box, but rather broader at the top end. The flowers are of a bright orange-yellow colour, produced in great abundance upon the young branches, and have a very sweet odour. Although the wood of this tree is known in Jamaica by the name of Ebony, it is not the true ebony-wood, that being produced by a totally different tree. The Jamaica Ebony is of a greenish-brown colour, very hard, and so heavy that it sinks in water; it takes a good polish, and is used in Jamaica for making

*Brya Ebenus.*

various small wares. Part of the wood known in commerce as Green Ebony, and which is much used by turners and dyers, is probably obtained from this tree. The

tough twiggy branches are used in Jamaica as riding-whips; and it is said that in former days they were kept at all the wharfs about Kingston to scourge the refractory slaves. [A. S.]

**BRYANTHUS.** A genus of *Ericaceæ* containing a single species, a native of Siberia and Kamtschatka, so nearly related to *Menziesia* that it is generally considered as belonging to that genus. It differs chiefly in having a pentamerous arrangement of the flower, although Ledebour, and apparently also Swartz, have seen specimens in fruit with four divisions of the calyx and capsule. The divisions also are deeper than in *Menziesia*. [W. C.]

**BRYOBIUM.** A supposed genus of small unimportant Orchidaceous epiphytes from India, not distinct from *Mycaranthus*, and like it now merged in *Eria*.

**BRYOLOGY.** The part of botany which treats of Urn-mosses.

**BRYONIA.** The technical name of the genus to which the common Bryony of the hedges belongs. Among the *Cucurbitaceæ* this genus may be known by the stamens and pistils being on the same plant, but in different flowers; by the calyx having five small teeth; the corolla five lobes; stamens five in three parcels, the anthers sinuous; style three-lobed, with capitate stigmas; and fruit globular, succulent. *B. dioica*, the Common Bryony, has a thick tuberous rootstock of considerable length, yellowish-brown, and wrinkled transversely on the outer surface. The stems that spring from this are annual, and rough. They climb by tendrils, and, what is very unusual, the direction of the spiral is now and then altered, so that after proceeding in one course for some distance, the tendril suddenly changes to an opposite direction. The leaves are angular, three to seven-lobed, the terminal or middle lobe being the longest; they are rough like the stem. The male flowers are in clusters, bell-shaped, greenish-yellow, and veined, the female blossoms are smaller, disposed in a corymb or umbel, and have a globular ovary which ripens into a scarlet berry, containing several flattened seeds. The male and female flowers are sometimes on different plants, hence the name *dioica*, but this is not always the case. The plant has a fetid odour, and possesses acrid, emetic, and purgative properties, and from its elegant appearance, especially in autumn when it adorns the hedges with its brilliantly coloured fruit, accidents are likely to occur to children and others incautiously tasting the fruit. The root is used as an application to bruises, and occasionally as a purgative; but it is unsafe from its uncertain and sometimes violent action, whence the French call it *Devil's-turnip*. Its acridity is due to a chemical substance called bryonin. The writer of this notice was once called on to ascertain what vegetable substance had been administered to a farmer, his family, and his cattle, by a

'wise man,' who purported to be able to remove the spell of witchcraft, under which he said they were all suffering. The man succeeded in obtaining considerable sums of money at different times from the credulous farmer, whose suspicions were at length awakened by the dangerous illness of some of the members of his family. It was not distinctly proved that the man had administered bryony, but the symptoms complained of corresponded with those which would be produced by that root, a quantity of which was found in the man's house, and also a powder which was found to consist of the leaves of the hart's-tongue (*Scelopendrium vulgare*). When the mandrake was more esteemed than it is now, this root was frequently sold for it, as it occasionally branches in a similar manner, and, indeed, was forced to do so, by being grown in moulds. Even now it is occasionally to be met with in herbalists' shops as mandrake. The young shoots of bryony may be used as a vegetable with impunity, and are said, when boiled, to resemble asparagus in flavour. This plant must not be mistaken for the black bryony (*Tamus communis*), also a climbing plant, but whose leaves are heart-shaped, smooth, and shining.

*Bryonia alba*, a central European species has similar properties to the English Bryony, as also have *B. americana* and *B. africana*. The root of *B. alba*, when cooked, is said to be eaten with impunity. The seeds of *B. callosa* are used in India as a vermifuge, and yield an oil used for lamps. *B. laciniosa*, *B. rostrata*, and *B. scabrella* are all used for medicinal purposes in India, while the leaves of some are boiled and eaten as greens. *B. epigra* was at one time supposed to furnish calumba root, which it resembles both in appearance and properties. It is used in India as an external application and for other medicinal purposes. [M. T. M.]

**BRYONY.** The common name for *Bryonia*. —, **BLACK.** *Tamus communis*. —, **RED.** *Bryonia dioica*.

**BRYOPHYLLUM.** A name expressive of the peculiarity that the leaves have, under certain circumstances, of producing small buds on their margins. The genus to which the name applies, belongs to the House-leek family (*Crasulacæ*), and is known by its bell-shaped distended calyx, which is four-cleft; the tube of the corolla somewhat quadrangular, the lobes of its limb, ovate or somewhat triangular; a number of gland-like compressed scales at the base of the carpels; and carpels on very short stalks. The leaves are unequally pinnate and fleshy. *B. calycinum*, when in flower, has loose panicles of drooping greenish-purple blossoms, which are very elegant. It is of particular interest from the formation of small buds at the notches on the margin of its leaves; sometimes these buds are produced naturally, but the plant may be made to form them by pos-

giving a detached leaf close down to the soil, when the buds will root into the ground, and form new plants. The species is a native of the Moluccas, Madagascar, the Mauritius, &c., and grows in dry situations in the clefts of the rocks. In the Mauritius it is used as a fomentation or poultice in intestinal complaints. [M. T. M.]

**BRYUM.** A large genus of Acrocarpous Mosses, now subdivided, but formerly almost equivalent to the natural family *Bryaceæ*: which see. [M. J. B.]

**BUBANIA.** A little known genus of *Plumbaginaceæ*, having the habit of *Gonolimon*, but possessing five clavate and not capitate stigmas. It differs from that genus, as well as from *Statice*, in having the styles united through a considerable extent of their length, and in the filaments being papillose at the base. The genus is founded on a single species from Algeria, which has not yet been satisfactorily described. [W. C.]

**BUBON.** A genus of *Umbellifera*, which has an obsolete calyx, and obovate entire petals, with the point bent inwards. The fruit is compressed and has a dilated flattened edge; while each half of it has on its outer surface four ridges, the central ones filiform, the lateral ones passing into the flattened margins of the fruit. In the channels between the ridges, in the interior of the fruit, are canals containing volatile oil, while on the inner face of the two halves are two such canals. The species are natives of the Cape of Good Hope, and have yellowish flowers. *B. Galbanum* secretes a resinous juice somewhat like galbanum. [M. T. M.]

**BUCAIL.** (Fr.) *Fagopyrum esculentum*.

**BUCCÆ.** The lateral sepals or wings of the flower of an acouite; seldom used.

**BUCHANANIA.** A genus of *Anacardiaceæ*, named in compliment to Dr. Buchanan Hamilton, a distinguished investigator of Indian botany. The genus consists of Indian trees with simple leathery leaves, hermaphrodite flowers in axillary panicles, with a five, or more rarely a three or four-cleft calyx; five petals rolled backwards; ten stamens shorter than the petals; and a ten-lobed disc wrapping round the ovaries, which are five in number, but only one perfect, the remaining four being represented only by the styles. The fruit is a drupe with one seed, borne on a little stalk within it. The seeds of *B. latifolia* are eaten by the natives as almonds, and they furnish an oil known as the cheromjee oil; the fruits also supply a black varnish. The unripe fruits of *B. lanceifolia*, according to Major Drury, are eaten by the natives in their curries. [M. T. M.]

**BUCHNERA.** A large genus of *Scrophulariaceæ*, generally distributed over the tropical and subtropical regions of the world. They are stiff scarcely-branched herbaceous plants, with the lower leaves opposite and the upper alternate, and with

flowers in terminal spikes. The calyx is tubular with five short teeth; the corolla tube is straight and slender, and the limb has five nearly equal spreading lobes, the two upper ones inside in the bud. The two pairs of stamens are included in the tube; they have obtuse one-celled anthers. The style is club-shaped. The capsule is straight, opening loculicidally in two entire valves. [W. C.]

**BUCHU.** The same as Bucku.

**BUCCIDA.** A genus of trees belonging to *Combretaceæ*, native of tropical America and the West Indies, with alternate wedge-shaped entire leaves, smooth or hairy on the margins, and axillary peduncles bearing rather small, spicate or capitate flowers. Calyx tubular, adhering to the ovary, above which it is bell-shaped and five-toothed at the margin; corolla none; stamens ten with long filaments; style simple, subulate; drupe one-seeded. The ends of the peduncles sometimes grow into spiny horn-like excrescences, from which the genus takes its name (*buccis*) or. *B. Buceras*, the Olive-bark, or Black Olive of Jamaica, produces wood which is valuable on account of its not being liable to the attacks of insects; the bark is also used for tanning purposes. [J. T. S.]

**BUCKBEAN.** *Menyanthes trifoliata*.

**BUCK-EYE.** An American name for the species of *Pavia* and *Æsculus*, especially *Æ. ohioensis*.

**BUCKLANDIA.** The name of a genus belonging to the order of Witch Hazels, having stamens and pistils in the same flower, or in different flowers on the same plant; or some plants have stamens only, while others have only pistils. The calyx is almost bell-shaped, adherent below to the seed-vessel; the anthers are supported on awl-shaped filaments. The flowers are in head-like groups, each subdivision of which consists of eight flowers. The name *Bucklandia*, which has also been employed to designate certain fossil species of plants, was given in honour of the late Dr. Buckland, well known as a geologist. The only species is an Indian tree with the general aspect of a poplar; its leaves are alternate, stalked, and variable in outline. [G. D.]

**BUCKLER-SHAPED.** Having the form of a small round shield, like a Highland target.

**BUCKTHORN.** The common name for *Rhamnus*. —, DYER'S. *Rhamnus infectorius*. —, SEA. *Hippophæ rhamnoides*.

**BUCKU.** A name applied in South Africa to several species of *Broussa*, especially *B. crenata*, *crenata*, and *terrestrifolia*.

**BUCKWHEAT.** *Fagopyrum esculentum*.

**BUCKWHEAT TREE.** *Mylocaryum histriatum*.

**BUD.** The young undeveloped branch or flower.

**BUDDLEIA.** A large genus of *Scrophu-*

*lariacea*, containing nearly eighty species from America, India, and South Africa. They are trees, shrubs, or herbs, generally tomentose or woolly, especially on the young branches, the under surface of the leaves, the peduncles and calyx, and sometimes even on the corolla. They have opposite leaves, and many-flowered peduncles, axillary or frequently in a terminal thyrse or panicle. The short campanulate calyx is divided into four equal teeth. The corolla is campanulate or tubular, with the limb spreading and divided into four equal teeth. There are four included stamens inserted either in the throat on very short filaments, or in the middle of the tube. The ovary is two-lobed, and bears a simple style with a capitate stigma. The capsule dehisces septically with two valves; it contains numerous small seeds. [W. C.]

**BUENA.** One of the genera of *Cinchonaceae* consisting of shrubs closely resembling the *Cinchona* itself, but distinguished by their solitary terminal flowers, and by the limb of the calyx being deciduous, so that the ripe fruit is not crowned by the calyx as in *Cinchona*. The species are natives of Peru and Western tropical America. [M. T. M.]

**BUETTNERIA.** *Byttneria*.

**BUFFALO BERRY.** *Shepherdia argentea*.

**BÜFFELHORN.** The South African name of the wood of *Burchellia capensis*.

**BÜFFELSBALL.** The South African name of the wood of *Gardenia Thunbergia*.

**BUFFONTIA.** A genus of the Alsineous group of *Caryophyllaceae*, containing small herbs or undershrubs, natives of central Europe, the Mediterranean region, and temperate Asia. They have stiff slender stems, often paniculately branched, and somewhat resembling the toad-rush (*Juncus bufonius*) in habit; leaves awn-shaped, closely applied to the stem; flowers small cymose, arranged in a spicate, racemose, or paniculate manner; calyx four-parted, scarious, compressed; petals four, white; stamens four to eight; styles two; capsule two-valved; seeds two. One species, *B. annua*, is said to have been found in Britain in Plukenet's and Dillenius's time, but has not occurred since, and it is not improbable that some other plant may have been mistaken for it. [J. T. S.]

**BUGBANE.** *Cnicifraga*.

**BUGINVILLEA.** *Bougainvillea*.

**BUGLE.** The common name for *Ajuga*.

**BUGLE-WEED.** *Lycopus virginicus*.

**BUGLOSS.** The common name for *Anchusa*. —, **SMALL.** *Lycopsis* or *Anchusa arvensis*. —, **VIPER'S.** The common name for *Echium*. —, **WILD.** The common name for *Lycopsis*.

**BUGLOSS.** (Fr.) *Anchusa officinalis*. —, **PETITE.** *Lycopsis arvensis*.

**BUGRANE COMMUNE.** (Fr.) *Ononis procurrens*.

**BUGWORT.** The common name for *Cimicifuga*.

**BUIS** (Fr.) *Buzus sempervirens*. — **DE MAHON.** *Buzus balearica*.

**BUISSON ARDENT.** (Fr.) *Crataegus Pyracantha*.

**BUKKUM WOOD.** The wood of *Cassia-pinta Sappan*, used as a dye stuff.

**BUKUL.** *Mimusops Elengi*.

**BULB.** A leaf-bud, the scales of which are fleshy, and which propagates an individual. —, **NAKED.** A bulb whose scales are loose and almost separate, as in the crown imperial. —, **SOLID.** A *Coma*; which see. —, **TUNICATED.** A bulb whose outer scales are thin and membranous.

**BULBIL.** An axillary bulb with fleshy scales, falling off its parent spontaneously, and propagating it.

**BULBILLARIA.** A genus of *Liliaceae*, scarcely distinct from *Gagea*, which the only species, *B. gageoides*, from Mount Libanus, closely resembles, differing only by having the ovary on a conspicuous club-shaped stalk within the perianth; there are no radical and only one cauline leaf, which is linear. The plant is remarkable for the small bulbs which occur in the axils of the leaf-like bracts. [J. T. S.]

**BULBINE.** A section of the Liliaceous genus *Anthericum*, containing several plants natives of South Africa. They have the segments of the perianth spreading and yellow; the filaments, or at least the alternate ones, bearded with short hairs; leaves somewhat fleshy, like those of the onion; root fasciculate; stem short. Several species are cultivated as greenhouse plants, and are not only pretty, but often fragrant. [J. T. S.]

**BULBOCAPNOS.** A section of the Fumariaceous genus *Corydalis*, containing the species which have a large tuberous rootstock, a persistent style, and a digitate process at the base of the seed, which has an embryo, of which the two cotyledons are united into one. Stem usually succulent, with few thin glaucous twice-termate leaves, having cut leaflets, and a terminal raceme of purple flowers, with paler markings. Several species occur in Europe and temperate Asia, but none are truly native in Britain, though one species, *Corydalis solida*, often found in gardens, flowering in spring, is naturalized in several places. This plant has solid tubers, a sheathing scale below the leaves, leaf-like bracts digitately cut, and rather large flowers. [J. T. S.]

**BULBOCASTANUM.** *Bunium Bulbo-castanum*.

**BULBOCHÆTE.** A genus amongst the

Conferveaceous articulated *Alga*, remarkable for its hyaline bristle-like branches, which are bulbous at the base. The fruit consists of globose capsules, with a green and then a dark red endochrome. The mode of impregnation in this genus, as also in *Ecdogonium*, is very curious. Some of the cells produce little bodies, which are furnished with flagelliform appendages, by means of which they swim about till they fit themselves on or near the swollen joints, which are to produce the spores. These bodies become clavate, with one or two joints, and just when the contents of the swollen cells are ready for impregnation, a lid comes off, and makes way for the exit of one or more globose spermatozooids, which are admitted to the endochrome of the female cells by means of a little aperture. After impregnation, the endochrome acquires a membrane, and after a time becomes free. The spore, when liberated, elongates—in a few hours attaining twice its original length. The endochrome, by successive division, gives rise to four distinct bodies, which acquire a nearly globular form, and are furnished at one extremity with two sets of ciliary processes, by means of which they move about, and thus appear in the condition of zoospores, which ultimately reproduce the species. *B. setigera* is our most common species, but others occasionally occur in this country. [M. J. B.]

**BULBOCODIUM.** Bulbous plants with the habit of the *Colchicum*, and members of the same family, *Melanthaceae*. The perianth consists of six coloured segments, with long taper claws or stalks, which form a slender tube; the upper portion of each segment is elliptical, and prolonged at the base into two small acute processes, so that the perianth may be described as consisting of six sagittate stalked segments. The stamens are six, attached to the segments of the perianth, and of unequal lengths; the style three-cleft, with simple stigmas. Ovary three-celled; ovules indefinite. Fruit a capsule, dividing when ripe into its component carpels. The species are pretty bulbous plants, natives of Europe, the Levant, &c. [M. T. M.]

**BULBODIUM.** The solid bulb of old botanists; the same as a corm.

**BULBONAC.** (Fr.) *Lunaria biennis*, and *rodovita*.

**BULBOSI PILI.** Hairs that proceed from a swollen base.

**BULBOSPERMUM.** A genus of *Liliaceae*, containing a small fibrous-rooted herb, from Java (*B. javanicum*), which has the stem somewhat bulbous at the base, with two or three long-stalked lanceolate radical leaves, which are membranous and many-nerved, but the sheaths and peduncles are frequently without any blade; scape short erect, with racemose flowers at the top; undermost bracts larger than the others, and frequently empty; flowers on long pedicels, with a six-parted greenish perianth; stamens six, monadelphous; ovary

three-lobed, opening at the top when ripe, and showing the seeds, which are as large as peas, three or four in each of the three cells of the capsule, and with a soft thick seed-coat. [J. T. S.]

**BULBOSUS.** Having the structure of a bulb; having bulbs.

**BULB-TUBER.** A corm; which see.

**BULL,** or **BULLET GRAPE.** *Vitis rotundifolia*.

**BULLACE.** *Prunus institia*.

**BULLACE PLUM, JAMAICA.** The fruit of *Melicocca bijuga*.

**BULLATE.** Blistered; puckered. When the parenchyma of a leaf is larger than the area within which it is formed.

**BELL-HOOF.** *Murucija ocellata*.

**BULLOCK'S HEART.** A name given to the fruit of *Anona reticulata*, a kind of custard apple.

**BULL-RUSH,** or **BULRUSH.** *Scirpus lacustris*; and sometimes *Typha*.

**BULLY,** or **BULLET TREE.** A name given in Guiana to a species of *Mimusopha*. —, **BASTARD.** *Bumelia retusa*. —, **BLACK.** *Bumelia tngens*. —, **JAMAICA.** *Lucuma mammosa*.

**BULRUSHWORTS.** A name given by Lindley to the *Typhaceae*.

**BUMELIA.** A Greek name for the common ash, but applied in modern times to a genus of *Sapotaceae*, having a corolla with a short tube, and a five-parted limb, at the base of each segment of which are two small scales. There are five fertile stamens attached to the tube of the corolla, opposite its lobes, and alternating with five petaloid barren stamens. The ovary has five one-seeded compartments, some of which, however, become arrested in their growth, so that the berry-like fruit frequently contains but one cavity and seed. The species consist of trees or shrubs, with a milky juice, a spiny stem, simple alternate leaves, and small white or greenish flowers. Some of them are sufficiently hardy to bear our climate, if protected by a wall, while others are grown in hot-houses. [M. T. M.]

**BUNCHOSIA.** Tropical American trees or shrubs, belonging to the order *Malpighiaceae*, and nearly allied to the genus *Malpighia*, but having the racemes of flowers axillary. Styles separate, or fused together; fruit fleshy, indurcent, externally smooth, without angles and containing two or three seeds, which are convex on the back. The flowers are for the most part yellow. Several kinds are in cultivation as stove shrubs. The seeds of one species, *B. armeniaca*, a Peruvian tree, are reputed to be poisonous. [M. T. M.]

**BUNGEA.** A genus of *Scrophulariaceae*, containing a single species, a native of America. It is a small herb, growing in densely leafy tufts. The leaves are linear,

and deeply trifid. The flowers are on short pedicels, with two bracts. The calyx is tubular at the base, and has four long leafy divisions of the limb. The upper lip of the corolla is acuminate. The stamens are didynamous, hid under the upper lip, and have two equal mucronate cells. The style has a capitate stigmatose apex. The ovoid capsule dehisces loculicidally, and contains few larlish seeds. This genus is very near to *Cymbaria*, from which, however, it is separated by its four leafy segments of the calyx, and its acuminate galea. From *Rhinanthus*, to which it was formerly referred, it differs in possessing two bracteoles under the calyx. [W. C.]

**BUNIAS.** A genus of *Cruciferae*; herbs from central Europe, the Mediterranean region, and temperate Asia, having erect branched stems, entire or pinnatifid, often runculate leaves, and elongated racemes of rather small yellow flowers, on short spreading pedicels. Pouch resembling a small four-sided ovoid pyramidal nut, often tuberculated or muricated, indehiscent two-celled; cells two-seeded; embryo with the cotyledons rolled up on themselves, which distinguishes the genus from all except *Brucaria*, which has a jointed pod breaking across into two segments.

[J. T. S.]

**BUNION.** A genus of tuberous-rooted Umbelliferous plants (*Astaceae*), chiefly inhabitants of Southern Europe and Western Asia. They are small herbaceous plants, seldom more than two feet high, and have very finely-cut leaves. Their flowers are white, and borne in compound umbels, generally destitute of an involucre, but occasionally with a few small bracts. The technical characters of this genus and its allies are derived from the fruit: in the present it is slightly flattened on two sides, and drawn in at the top, terminating in two straight styles; each half of the fruit has five indistinct longitudinal ribs, with several oil cells between them.

*B. scariosum* is a native of Western Europe, but is found wild in Britain. This grows erect about a foot or more high, with a few branches towards the top. Its leaves are very few in number, and very finely divided and sub-divided into numerous slender narrow divisions—those on the upper part of the stem having much finer divisions than the lower ones. The round tuberous roots of this plant have a sweetish aromatic taste, mingled with a considerable amount of acridity, which renders them unpleasant eating while raw, although they are often eaten in that state by children; but when boiled or roasted, they are palatable, resembling the chestnut in taste—hence the name Earth-chestnuts; they are also called Pig-nuts, Ar-nuts, Jur-nuts, Yur-nuts, Kipper-nuts, &c.

*B. ferulagolium*, which grows in the islands of Cyprus and Candia, produces tubers as large as filberts, which are eaten

by the Greeks under the name of Topana. It has branching stems about a foot in height, and leaves primarily divided into three divisions, each of which are then subdivided into three leaflets. [A. S.]

**BUN-UCHRO.** An Indian name for *Urena lobata*.

**BUNT.** The common name of *Tilletia caries*, a parasitic fungus belonging to the section *Coniomycetes*. *Tilletia* differs from other genera of the group *Ustilaginæ* in the perfectly globose spores having a cellular outer coat. These are at first developed from the ultimate branchlets of a very delicate web which at length completely vanishes, so that the seed in which they grow contains nothing but spores. These are held together for a long time in consequence of the toughness of the outer coat of the seed, and in this way the bunted grains are carried home with the rest of the produce, so that when the grain is threshed the spores of the bunt are dispersed, and many of them adhere to the seed-corn, ready to germinate when the seed is sown. The first thread protruded by the spores is thick and coarse, so that it cannot penetrate the tissues of the sprouting grain; but a tuft of far more delicate threads soon crowns its apex, and after becoming united with each other by means of little lateral processes, they produce secondary spores, which in their turn germinate. As the wheat crop often suffers seriously from bunt, many measures are adopted by the farmer to kill the bunt-spores. Arsenic and corrosive sublimate are inellegant because the grain, if not sown at once, is apt to lose its power of vegetating; sulphate of copper has not the same inconvenience, and is much used, as is also quicklime slacked with boiling water. The best practise is perhaps that pursued in some parts of France. The wheat is thoroughly wetted with a strong solution of Glauber's salts (sulphate of soda), and then dusted with quicklime. The effect of this is to set the caustic alkali free, while the sulphur and lime combine to form gypsum. Bunt scarcely occurs in barley, but has been found in Algiers on *Hordeum murale*. Another species of *Tilletia* occurs on *Scorpium*, and a third species, which has been communicated by the late Dr Curtis, has been found on wheat in the United States. [M. J. B.]

**BUNYA-BUNYA.** *Araucaria B. nobilis*.

**BUPHANE.** A small group of *Amayrids*, remarkable in having precocious flower-scapes, supporting from 100 to 200 or more flowers in a single head. The flowers have a straight cylindrical tube, and a regular six-parted expanded limb, their filaments being erect and distinct from the tube. The capsule which succeeds them is turbinate and dry, three-valved, with numerous distinct ovules. Only four species are referred to the genus by Herbert, and these are all South African. The peduncles are at first crowded and suberect, but diverge so as to form a spherical head. *B. toxiocaria* is called

the Poison Bulb, and is said to be fatal to cattle. The bulbs of *B. disticha* are met with as large as a man's head. The former of these produces crowded umbels of flesh-coloured flowers, the segments of which are linear-lanceolate, and its leaves are elongately lorate. [T. M.]

**RUPHTHALMUM.** A family of Compound flowers deriving their name (equivalent to Ox-eye) from the broad open disk of their flowers. Among the plants of this family most frequently cultivated in English gardens are *B. grandiflorum*, a herbaceous perennial growing about a foot and a half high, with narrow smooth leaves, and large yellow flowers; and *B. coratfolium*, also a herbaceous perennial, forming a large tuft; the root-leaves are heart-shaped, the upper ones smaller, egg-shaped and sessile; the flowers large, bright yellow with long rays. Both are natives of central Europe. [C. A. J.]

**RUPLEURUM.** Hare's-ear, Thorow-wax, or Thorow-leaf. The only common English species of this strongly-marked family of Umbelliferous plants is *B. rotundifolium*, which occurs in corn-fields on a chalky soil, especially about Swaffham and in Cambridgeshire. It may be known by its roundish-oval leaves, which are alternate, and so extended at the base that every branch doth grow thorowe everie leafe, making them like hollowe cups or sawcers (Gerarde). The flowers are small and of a greenish-yellow hue, and far less conspicuous than the large bracts at the base of the partial umbels. *B. fruticosum* is a shrubby species, a native of the South of Europe, with purplish branches and sea-green leaves. Several other species are cultivated, all of which are more or less remarkable for the unusual development of the floral bracts (involucre), and are of easy cultivation. French, *Bupleure*, *Oreille de lièvre*; German, *Hufenshrchen*. [C. A. J.]

**BUPLEVER.** An English name adapted from the French, proposed by Bentham for *Bupleurum*.

**BUR-BARK.** The fibrous bark of *Triumfetta semitriloba*.

**BURCHARDIA.** An Australian genus of the Colchicum family (*Melanthaceæ*). The perianth is coloured, of six slightly-stalked segments, each having a nectariferous pore near the base; stamens six, inserted on the very base of the segments of the perianth; anthers peltate, opening outwardly; ovary triangular, containing three compartments, each with several ovules in two rows; styles three. Fruit a capsule, opening by the separation of its constituent carpels. *B. umbellata* is in cultivation; it is a herbaceous plant with thick rootlets, linear sheathing leaves; flowers white in umbels. [M. T. M.]

**BURCHELLIA.** A name given in honour of Mr. Burchell, an African traveller, and used to denote a genus of *Chinchonaceæ*.

The characteristics of this genus are the flowers closely packed in a head, surrounded by a few bracts; corolla funnel-shaped, swollen above the middle; limb five-cleft, small, naked at the throat; stamens inserted above the middle of the tube of the corolla; anthers on very short filaments; stigma club-shaped. The fruit is succulent, two-celled, many-seeded, crowned by the deeply five-cleft calyx. The species are shrubs with handsome flowers, and are natives of S. Africa. *B. capensis* and *B. parviflora* are grown in greenhouses for the sake of their clustered handsome scarlet flowers. [M. T. M.]

**BURDEE.** An Arabic name for *Papyrus antiquorum*.

**BURDOCK.** The common name for *Arctium Lappa*; also applied to *Centothea lappacea*. —, **PIRAIRIE.** An American name for *Stiphium teretanthaceum*.

**BURKEA.** A genus of the Pen family, and belonging to the section with regular flowers. *B. africana* is the only species of the genus, and is a shrub or sometimes a small tree, thirty feet high, with twice pinnate leaves, and very numerous oval leaflets from one to three inches long, and when young covered with silvery hairs. The flowers are small, white, and fragrant, disposed in panicles made up of long slender branching spikes. The pods are stalked, thin, and about one and a half inches long, with one or two seeds. This is one of the many plants which are common to the eastern and western sides of tropical Africa. The genus is named in compliment to Mr. J. Burke, a plant collector, who made extensive collections of S. African and N. American plants. [A. A. B.]

**BURLINGTONIA.** A genus of epiphytal Orchids inhabiting the tropics of Brazil. The species have large and often fragrant white yellow or pink flowers attached to a weak drooping or pendulous spike. All that are known are in cultivation in this country.

**BURMANNIACEÆ.** A family of Monocotyledons, allied to orchids in their inferior ovary, either three-celled or with three parietal placentas, in their trimerous flowers, and especially in their minute seeds, with a loosely netted testa enclosing an apparently homogeneous nucleus or embryo; but differing in their perfectly regular flowers, with three to six distinct stamens and a central simple or three-cleft style. They are all herbaceous, with blue or white flowers, inhabiting marshy or shady places. In some genera the annual slender stems have no leaves except small colourless scales, which led former botanists to suppose them to be root parasites; but it has now been ascertained that they grow on rotten leaves and other decayed vegetable substances, and not on living plants. There are scarcely more than thirty species of *Burmanniaceæ* known, all tropical, except one North American *Burmanniæ*. They are distri-

buted into ten or eleven genera, including *Tacca*, which some botanists treat as a distinct family under the name of *Tac-*

others of the species furnish a resinous substance. The shrubs are natives of the West Indies. [M. T. M.]

**BURMANNIA.** A genus of *Burmanniaceae*, the principal one of the family, although consisting of only six or seven species. It is distinguished by the three-winged or three-angled ovary and capsule, completely divided into three cells, with numerous seeds attached to the inner angle of each cell. They are mostly marsh plants, with short flat sedge-like leaves, forming radical tufts or crowded at the base of the stem, and terminal blue flowers in short simple or two or three-branched spikes. One species, however, *B. capitata*, is a slender almost colourless plant, without other leaves than minute scales, and with very small capitate flowers. They are natives of the tropical regions of Asia, Africa, and America, one species extending northward as far as Virginia.

**BURNET, GARDEN.** *Poterium Sanguisorba*. —, **GREAT.** *Sanguisorba officinalis*. —, **LESSER.** The common name for *Poterium*. —, **SALAD.** *Poterium Sanguisorba*.

**BURNING BUSH.** An American name for *Euonymus atropurpureus*, and *E. americanus*; also sometimes applied in gardens to the Artillery plant, *Pilea serpyllifolia*.

**BURR.** The Burdock, *Arctium Lappa*.

**BURSARIA.** A genus of South Australian and Tasmanian shrubs belonging to *Pittosporaceae*. Branches not infrequently spiny; leaves alternate, subsessile, obovate wedge-shaped retuse and entire, or oblong-linear and toothed; peduncles terminal, ternate, or panicle, the flowers small, white, sometimes tinged with pink outside; sepals, petals, and stamens, five each. Ovary free; style thread-like. Capsule obovoidate, compound, extremely like that of the shepherd's purse (*Capsella Bursa-Pastoris*), incompletely two-celled, two-valved at apex; seeds one or two in each cell. [J. T. S.]

**BURSERIA.** One of the genera of *Amyridaceae*, consisting of trees with alternate compound leaves, flowers in axillary clusters, a small three to five-parted calyx, a corolla of three to five petals, larger than the segments of the calyx, inserted with the six to ten stamens beneath an entire circular disc. Ovary sessile, with three compartments, each containing two suspended inverted ovules, placed side by side. Fruit globose or somewhat angular, with a leathery outer rind bursting into three pieces, and an inner hard shell, containing three bony seeds, surrounded by a small quantity of pulp, or a single seed, by the abortion of the rest. *B. pantocista*, called Bois de Colophane in the Isle of Bourbon, contains an abundance of oil, like turpentine, which exudes when the bark is pierced, and speedily congeals, till it acquires a buttery consistence;

others of the species furnish a resinous substance. The shrubs are natives of the West Indies. [M. T. M.]

**BURSICULA** (adj. **BURSICULATE**). A small purse. A pouch-like expansion of the stigma, into which the caudicle of some orchids is inserted.

**BURSINOPETALUM.** A genus of *Oleaceae*, containing an Indian tree (*B. arborescens*), which has ovate acuminate leathery leaves and small panicle white flowers, remarkable for the form of the petals, which have an inflexed lobe at the point, and terminate in two small sharp teeth. Calyx superior, with a five-cleft limb; stamens five, connivent. Fruit a one-celled drupe. Bentham and Hooker include this plant in the Connaceae genus *Mastrea*. [J. T. S.]

**BURTONIA.** A genus of dwarf heath-like shrubs belonging to the pea-flowered section of the Leguminosae family, all of them natives of West Australia. They have simple or trifoliate sessile leaves, which are usually awl-shaped. The flowers are axillary and often thickly-gathered on the ends of the branches; the corollas rich purple, the keel generally of a deeper colour, and the standard having sometimes a yellow blotch at its base. The pod is small, ovate, and sessile, with two seeds. The species are very pretty objects when in flower, and are often to be met with in greenhouse collections. *B. scabra* was introduced in 1803, but there are now five species in cultivation and seven species known. The genus bears the name of Mr. D. Burton, who collected plants in W. Australia for the Kew Gardens. [A. A. B.]

**BURWEED.** The common name for *Xanthium*.

**BUSBECKIA.** The name of a genus of *Capparidaceae* characterised by a calyx of two sepals, valvate in the bud, deciduous; petals seven, inserted at the base of the hemispherical receptacle, unequal, imbricate in the bud; stamens several, inserted on the torus; ovary on a long stalk, one-celled, with two or more parietal placentas, bearing several curved ovules; stigma sessile, round; berry globose, leathery, rough on the outer surface; seeds kidney-shaped, imbedded in pulp, and with a leathery coat. A Norfolk Island shrub of climbing habit, with alternate leaves furnished with spiny stipules, and solitary axillary stalked flowers. The fruit is of the size of a large orange. The *Busbeckia* of Martins is now included in the genus *Salpichroma*. [M. T. M.]

**BUSH SYRUP.** A saccharine fluid obtained from the flowers of *Protea mellifera*, in the Cape Colony.

**BUSSEROLE.** (Fr.) *Arctostaphylos Uva-ursi*.

**BUSSU.** A S. American name for *Mantaria saccifera*.

**BUTCHER'S BROOM.** *Ruscus*. — *tus*; also a common name for *Ruscus*.

**BUTEA.** The three or four species constituting this genus of Leguminous plants (*Fabaceae: Papilionaceae*) form either small trees or large climbing shrubs, and are all natives of India. Their flowers are produced in racemes consisting of numerous flowers arranged in threes. The calyx has two small bracts near its base, and is usually covered with black velvety down; it is bell-shaped and two-lipped, the upper lip being nearly whole, and the lower one three cut; the corolla is papilionaceous; the stamens are ten in number, nine of them being united into a tube, and the tenth separate. The fruit is a stalked flattened thin and membranaceous pod, containing one seed placed near the apex.

*B. frondosa*, the Dhak or Pulas of India, is a fine tree growing to about thirty or forty feet high, common in the jungles of Bengal. Its leaves are composed of three roundish leaflets, covered with silky hairs, somewhat resembling the pile of velvet; the young branches likewise are hairy. The racemes of flowers are produced early in spring, before the leaves have made their appearance; each individual flower being about two inches long and of a very bright orange-red colour. Dr. Hooker states that when in full flower the Dhak tree is a gorgeous sight, the masses of flowers resembling sheets of flame, their 'bright orange-red petals contrasting brilliantly against the jet-black velvety calyx.' The Dhak tree supplies the natives of India with several articles of a useful nature. The most important of these is the red astringent juice which exudes from wounds in the bark, and which, when hardened by evaporation, forms one of the brittle ruby-coloured substances called kino, this particular variety being termed butea kino or gum butea. Sometimes, however, it goes under the name of Bengal kino; but it must not be confounded with East Indian kino, which is produced by *Pterocarpus Marsupium*. This substance is procurable in large quantities, but it has not yet come much into use. The natives employ it for tanning leather, and it has been tried in this country for the same purpose, but the dark colour which it communicates to the leather is considered objectionable; it might probably be turned to account by the dyer. The flowers are called teesoo or keesoo in India, and afford either a beautiful bright yellow, or a deep orange-red dye; but unfortunately these tints are not permanent. A coarse fibrous material obtained from the bark of the stems and roots is used in India for caulking the seams of boats as a substitute for oakum. The lac insect (*Coccus*) likewise frequents the Dhak tree, and by its punctures in the young twigs causes the formation of the substance known as stick-lac, which is used in the manufacture of sealing-wax and in dyeing. And, finally, the seeds yield a small quantity of oil, called moodooga oil, which the native doctors consider to possess anthelmintic properties.

*B. superba* is a large climbing shrub with leaves resembling those of the last species; its flowers, also, are of a similar bright orange-red, but rather larger, so that when in full flower the plant presents a very gaudy appearance. Its products are similar to those of the dhak; the flowers yielding a colouring matter, and the juice hardening into kino.

*B. parviflora* is a shrubby climber resembling the last in general appearance, but having very much smaller flowers than either of the preceding. The gum of this species is given, dissolved in arrack, in hysteria and colic. [A. S.]

**BUTOMACEÆ.** (*Butomads*; the *Flowering Rush* family.) A natural order of Hypogynous Monocotyledons belonging to Lindley's Alismal alliance. Aquatic plants, often milky, with very cellular leaves, and umbellate showy flowers. Perianth of six pieces, the three inner (corolla) being coloured like petals. Stamens either below or above twenty in number, hypogynous. Ovaries three to six or more, either separate or united; ovules numerous. Fruit consisting of achenes or follicles, separate or united. Seeds numerous, attached to a net-like placenta, which is spread over the whole inner surface of the fruit: no albumen. Natives of the marshes of Europe and Siberia, the north-western provinces of India and equinoctial America. The Flowering Rush, *Butomus umbellatus*, is an ornament of our lakes; its underground stem is roasted and eaten in Asia. There are four genera and seven species. Illustrative genera: *Butomus*, *Limnocharia*. [J. H. B.]

**BUTOMUS.** The Flowering Rush: one of the stateliest and most elegant of English aquatics, improperly called a rush, though the similarity of its long smooth knotless flower-stalk to the stalk of the bulrush (*Scirpus*) sufficiently accounts for the name having been given. Gerard, who suggests the name of Lillie-grasse, calls it the Water Gladiolus or Grassie Rush, and says, that 'Of all others it is the fairest and most pleasant to behold, and serveth very well for the decking and trimming up of houses, because of the beaultie and braverie thereof; consisting of sundry small flowers, compact of six small leaves, of a white colour mixed with carnation, growing at the top of a bare and naked stalk, five or six foote long, and sometime more.' The leaves are narrow, triangular, and very cellular, shorter than the flower-stalks, but they, nevertheless, greatly exceed two feet, the dimensions assigned to them in botanical works, as the plant generally grows in water at least two or three feet deep. The bottom of the main stalk as well as the partial flower-stalks are frequently tinged with purple. The flowers are large, of six sepals, and contain each nine stamens and six styles. The seeds and root were formerly employed medicinally, and in the north of Asia the latter is roasted and eaten. A variety is cultivated which has striped leaves. (French, *Butome*. German, *Blumenbutus*.) [C. A. J.]

**BUTTER OF CACAO.** A pleasant concrete-oil, obtained from the seeds of *Theobroma cacao*. — **OF CANARA.** Piny tallow, a solid oil obtained from the fruits of *Fateria indica*.

**BUTTER AND EGG.** The double flowered variety of *Narcissus (Queltin) aurantiac*.

**BUTTER AND TALLOW TREE.** *Pentadesma butyrosa*.

**BUTTER-BUR.** The common name of *Petasites*, a group of the *Tussilago* family.

**BUTTERCUP.** The popular name for *Ranunculus acris* and its near allies, *R. repens* and *bulbosus*.

**BUTTERFLY-PLANT.** *Oncidium Papilio*. — **INDIAN.** *Phalanopsis amabilis*.

**BUTTERFLY-SHAPED.** The same as *Papilionaceae*.

**BUTTERFLY WEED.** *Asclepias tuberosa*.

**BUTTER TREE, INDIAN.** *Dacrydium butyraceum*. — **AFRICAN.** The Shea Tree, *Bassia Parkii*.

**BUTTERWEED.** *Erigeron canadensis*.

**BUTTERWORT.** *Pinguicula*.

**BUTTON-BUSH.** An American name for *Cephalanthus*.

**BUTTON-FLOWER.** The common name of *Gomphia*.

**BUTTON-TREE.** *Conocarpus*.

**BUTTON-WREED.** The common name of *Spermacoce*. Also an American name for *Diodia*.

**BUTTON-WOOD.** *Cephalanthus occidentalis*; also an American name for *Platanus*.

**BUTUA.** The Brazilian name for the roots of *Botryopsis platyphylla* and *B. cinerea*. According to Pereira, Butua root is the root of *Cissampelos Pereira* or *Pereira Brava* of commerce. — **DO CURVO.** The Brazilian name of the roots of *Cochlospermum insignis*.

**BUKBAUMIA: BUKBAUMIACEÆ.** A most singular genus and division of Mosses, in which the capsule bears an extraordinary proportion to the vegetative part, which is sometimes all but obsolete. It has a double peristome, of which the outer one is either nearly obsolete, or consists of a triple or quadruple circle of teeth, and the inner forms a truncate cone. The species are few in number. Three are found in this country: *B. phycium foliosum*, which has a nearly sessile ovate-conical capsule, and occurs on the ground and on rocks in sub-Alpine districts; another, *Bukbaumia aphylla*, remarkable for its long-stalked capsule being flat on one side, and convex on the other, like the roses of cer-

**BUXUS.** A small but important genus of Spurge-worts (*Euphorbiaceæ*), one species of which is the well-known Box-tree of our gardens. They are shrubs or small trees, with opposite entire evergreen leaves, and their flowers being produced in clusters from the angles of the leaves, each cluster consisting of several male flowers, surmounted by one or two females. They have a calyx, consisting of four minute sepals, the males having four stamens, and the females three styles. The fruit is three-celled, containing two shining black seeds in each cell, and splitting open when ripe.

The Common or Evergreen Box-tree (*B. sempervirens*) is a native of both Europe and Asia. In Europe it extends as far north as the fifty-second parallel of latitude, and is found plentifully on the coast of the Black Sea, also in Spain, Italy, and the southern and eastern provinces of France. In this country the only place where it is really indigenous is Boxhill in Surrey. In Asia it is found in Persia, Northern India, China, and Japan. It varies considerably in height, some varieties growing as high as twenty or thirty feet, with a trunk eight or ten inches in diameter; while others never exceed three or four feet, and have very small stems. As commonly seen in this country it is either a shrub eight or ten feet high, or artificially dwarfed and only a few inches high. Its leaves vary from half an inch to an inch long, and from an egg-shaped to an elliptical form; they are of a shining deep-green colour, and of a thick leathery texture. The wood of the Box-tree has long been celebrated for its hardness and closeness of grain; it is mentioned by Theophrastus, and also by Pliny, the latter asserting that it is as hard to burn as iron. Other early authors also mention it as being used for musical instruments, carving, turnery, &c. Its chief characteristics are excessive hardness, great weight, evenness and closeness of grain, light colour, and being susceptible of a fine polish. These are the qualities that render it so valuable to the wood engraver, the turner, the mathematical and musical instrument makers, and others. Between 2,000 and 3,000 tons are annually imported; in 1838, the imports amounted to 2,704 tons, valued at 28,270*l*. The finest quality, and the best suited for the engraver, comes from Odessa, Constantinople, and Smyrna, being grown in the vicinity of the Black Sea; it is generally in logs about four feet long, and seldom more than eight or ten inches in diameter. For the use of the engraver these logs are cut across the grain into slices about an inch thick. In the early days of wood engraving, these slices were cut lengthways with the grain, and it was not till the middle of the last century that the present method was adopted. For the turner and other manufacturers of small wares, wood of an inferior description from smaller trees is suitable, and large quantities of box-wood articles are consequently made in different parts of France, where the tree abounds, though it does not attain a great size. The Box-tree is greatly

added *B. inulata* to the list of our British species.

[M. J. B.]

employed in ornamental gardening, particularly for the formation of geometric designs. The kind commonly used for the edges of flower-beds is merely a dwarf variety of the common species.

The *Miuorca* Box, *B. balcarica*, is a native of several of the Mediterranean islands and of Asia Minor. It is a larger tree than the last, growing sometimes as high as sixty or eighty feet, with a straight smooth trunk; the leaves also are of a much paler green than those of the common box, and much larger, being about three inches long and of an elliptical shape. The wood much resembles that of the common box, but is said to have a coarser grain; it no doubt forms part of the wood exported from Constantinople and Smyrna. [The common Box-tree, *B. sempervirens*, is the badge of the clan McIntosh, and its variegated variety that of the McIntoshes.] [A. S.]

**DYBLIS** A genus of *Droseraceae* containing Australian herbs resembling sundews (*Drosera*). They have very short stems, and tufts of linear leaves, with revolute margins. The peduncles are axillary, one-flowered; sepals and petals five each, the latter blue; stamens five; style simple. The capsule, which is obovate, ventricose and two-celled, contains but few seeds. [J. T. S.]

**BYRSANTHES**. One of the genera of the order *Labelliales*. Calyx tube adnate to the ovary, its limb five-parted; corolla funnel-shaped, leathery (hence the name Leather-flower), its limb five-parted, with erect equal segments; stamens five, inserted with the corolla on to the tube of the calyx, the anthers coherent in a tube, some or all of them hairy at the top. Ovary two-celled, containing several ovules, adhering to the two-lobed placenta; style not projecting from the flower; stigma two-lobed, the lobes spreading, roundish, hairy. Shrubs inhabiting the Andes, covered with snow-white hairs; flowers stalked. [M. T. M.]

**BYRSONIMA**. An extensive genus of plants belonging to the order of *Malpighiads* (*Malpighiaceae*), and containing about eighty species, inhabitants of Tropical America. They form shrubs or small trees, seldom exceeding thirty or forty feet in height, and have opposite entire leaves, destitute of the glands common to those of allied genera. Their flowers are produced in racemes at the ends of the branches, and are generally of a yellow colour; the calyx has ten glands or wart-like swellings, two at the base of each sepal; their ten stamens are connected together by a ring at the base, and they have three distinct styles terminated by pointed stigmas. Their fruit has a fleshy pulp surrounding a hard three-celled stone, containing three seeds.

*B. Cumingiana* is common in New Grenada, Panama, and Veraquas, forming a small tree about twenty-five or thirty feet high. Its leaves are lance-shaped, about three inches long and an inch and a half wide, the widest part being at the top end; both their upper and under surfaces, but particularly the latter, are covered with a thick coating of light brown woolly scurf, which gives them a rather dull appearance.

The racemes of flowers are about six inches long, and being of a deep yellow colour, give the tree a fine effect when in full flower. In Panama it is called Nanci, and the inhabitants consider the bark an efficacious remedy in certain skin diseases common in that country; they likewise use the wood for building purposes, and eat the small acid berries.

*B. crassifolia* is a native of the West Indies and the Northern part of South America, where it forms a small tree about fifteen feet high. It has oval leaves about four inches long and two broad, smooth upon the upper surface, and covered with brownish silky down underneath. The bark possesses astringent properties, and is used for tanning leather; it is also said to be useful as a medicine, a decoction being employed as an antidote to the bite of the rattlesnake; and in Cayenne it is employed as a febrifuge. The Carib Indians call the plant Moulle-le, and use its bark for painting their paddles and arrow-heads.

*B. spicata* is a tree thirty or forty feet high, growing in some of the West Indian islands and in Brazil. It has lance-shaped blunt-pointed leaves about four or five inches long and an inch and a half broad, of a shining green upon the upper side and a dull rusty brown colour beneath. The bark of this, as indeed of all the species of the genus, is very astringent, and is commonly used by the Brazilian tanners, under the name of Muruxi bark; it also contains a colouring matter, and is used by the Indians for dyeing their garments red. The yellow acid berries of this plant are very good eating when ripe, but rather astringent; they are considered to act beneficially in cases of dysentery.

*B. verbascifolia* is a small shrub with a short thick knotty stem, the wood of which is of a bright red colour. Its leaves are about ten inches long and of an obovate shape, i.e. having the top half broader than the bottom; they are generally woolly on both sides, and a microscopic examination of the hairs of this and other species will show them to be centrally attached. In Brazil and Guiana, where this plant grows, a decoction of the roots and branches is used for washing ulcers, and is considered to possess healing properties. [A. S.]

**BYSSACEOUS**. Composed of fine entangled threads.

**BYSSI**. A name which formerly included a heterogeneous mass of perfect and imperfect plants of various affinities, but is now exploded, the term byssoid alone being retained to express a peculiar fringed structure in which the threads or fascicles of threads are of unequal lengths. [M. J. B.]

**BYSSUS**. The stipe of certain fungals.

**BYTTNERIEE** (*Byttneriaceae*). A tribe of the natural order *Sterculiaceae*, regarded by some botanists as a distinct order, and referred by Lindley to his *Malval* alliance of *Thalamiflorae* *Exogonae*. They consist of trees or shrubs, with hermaphrodite flowers, in which respect they differ from the true

*Sterculia*, being further distinguished by having their five petals concave or cucullate at the base. Benthain and Hooker associate the *Byttneria*, under *Sterculiaceae*, with the *Sterculian*, *Helicterea*, *Eriofanua*, *Dembyea*, *Hermania*, and *Lasiopetalum*, which are the several tribes into which the plants referred to this order are distributed. The nutritious beverages known as Chocolate and Cocoa are prepared from the seeds (*Cacao* beans) of *Theobroma Cacao*, a small tree found in the forests of Demerara; the seeds of which contain a tonic substance called theobromine, allied to theine, while a fatty oil is expressed from them called the butter of cacao. From the pulp of the fruit a kind of spirit is distilled. Illustrative genera:—*Glossolemon*, with palmnerved leaves; *Abroma*, with palmlobed or entire leaves; *Theobroma*, with simple penninerved leaves; *Herrania*, with palmated or digitate leaves; *Guanuma*, with simple leaves; *Buettneria*, noticed below; and *Eulimbia*, with the leaves simple or lobed. [J. H. B.]

**BYTTNERIA** (*Buettneria*). This genus gives its name to the group to which it belongs. The species are numerous, and are widely distributed, being found in India, Java, and Madagascar, in the Old World, and in America as far north as Texas, reaching south to Buenos Ayres, and attaining their greatest number in Brazil. They are very diverse in appearance, some being small erect herbs about one foot high; others tall straight bushes with winged or angled stems and very narrow leaves; *B. caudatifolia* grows to a tree thirty feet high, with long-stalked heart-shaped leaves; but the greater number are scandent prickly bushes, scrambling over other plants as the brambles do in our hedges. The leaves in all the species are simple, and in the greater part more or less heart-shaped in form, with entire or notched margins. The flowers are small, generally dark purple in colour, and arranged in axillary simple or compound umbels. The petals are curiously hooded at the apex, and from the outer surface of the hood grow one, two, or three strap-like appendages. The fruit is a five-celled woody capsule, spherical in form, from half an inch to two inches in diameter, and armed with long or short rigid bristles. Each cell contains one seed. *B. heterophylla*, a native of Madagascar, is often to be found with entire or three-lobed leaves on the same plant; it is an extensive climber, scrambling over the tops of the highest forest trees, and is said to cover nearly the whole slope of the sides of the mountain called Tantanarivo, and to occur nowhere else in the island. The name is named in honour of David S. A. formerly professor of botany at Göttingen. [A. A. B.]

**BYWA.** A Japanese name of *Ericthobotrya*, the Lo-quait of the Chinese.

**CAA-APIA.** A Brazilian name for *Dorstenia brasiliensis*.

**CAA-ATAICA.** *Tundellia diffusa*.

**CAA-CUA.** A Brazilian name for some scrophulariaceous plant.

**CAAPÉBA.** The Brazilian name for the *Pareira brava*, *Cissampelos Pareira*.

**CAAPIM DE ANGOLA.** *Panicum spectabile*, a fodder grass of Brazil.

**CAAPOMONGA.** *Plumbago scandens*.

**CAA-TIGUÁ.** A Brazilian name for *Moschoxyylon Catigua*, a plant which imparts a bright yellow stain to leather.

**CABALLINE ALOES.** Horse Aloes, *Aloe caballina*.

**CABARET.** (Fr.) *Asarum europæum*. — **DES OISEAUX.** *Dipeacus sylvestris*.

**CABBAGE.** The common name for *Brassica*; specially applied to the plane-leaved hearting garden varieties of *Brassica oleracea* —, **DOGS.** *Thelygonum cynocrambe*. —, **KERGUELEN'S-LAND** *Pringlea antiscorbutica*. —, **ST PATRICK'S.** *Saxifraga umbrosa*. —, **SKUNK.** The fetid antispasmodic *Symplocarpus foetidus*.

**CABBAGE-BARK TREE.** The Worm Bark, *Andira inermis*.

**CABBAGE-PALM.** *Arca oleracea*.

**CABBAGE-TREE.** A common name for the genus *Arca*; also a garden name for *Eichia nerifolia*. —, **AUSTRALIAN.** *Corypha australis*, the leaves of which are made into plait for hats, baskets, &c. —, **BASTARD.** *Andira inermis*.

**CABBAGE-WOOD.** *Eriodendron anfractum*.

**CABEZA DE NEGRO.** Negro's head, the Columbian name for the fruit of *Phytolophus macrocarpa*.

**CABOMBACEÆ.** (*Cabombæ*; *Hydrophilidæ*; *Water-shieldæ*.) A natural order of Thalamifloral Dicotyledons belonging to Lindley's Nymphaeal alliance. Aquatic plants with floating shield-like leaves; sepals and petals three or four, alternating; stamens six to thirty-six. Carpels distinct, two to eighteen; seeds not numerous; embryo in a membranous bag, outside abundant fleshy albumen. The plants are obviously allied to the Water-lilies. They are found in America, from Cayenne to New Jersey, as well as in New Holland. There are two genera, *Cabomba* and *Hydrophilis*, which comprise three species. [J. H. B.]

**CABOMBA.** A genus of aquatic herbs giving its name to the small order of *Cabombaceæ*. The species are small water plants with shield-shaped entire floating leaves, and finely-cut submerged ones, like those of the common water ranunculus. The flowers have three sepals, four

or five petals, six stamens with ovate four-cornered anthers, and two ovaries. They are natives of North America. [M.T.M.]

**CABOTZ.** *Brayera anthelmintica*.

**CACALIA.** The generic name of plants belonging to the Composite order, distinguished by the flowers being all tubular, and having both stamens and pistils: the heads of flowers surrounded by a single row of leaf-like bodies varying from five to thirty in number. The appendage on the top of the fruit or seed is in the form of a short cone, hairy at the base; the fruit is oblong and smooth. The species are perennial herbs with the leaves alternate, toothed or lobed, and the flowers varying in colour. Most of them are plants of peculiar aspect, owing to their clumsy fleshy stems, and the dingy colour of their leaves. They are natives of the warmer parts of America, middle Asia, and Eastern Africa. The Chinese employ as food the leaves of *C. procumbens*, and those of *C. ficoides*, a native of the Cape, are also wholesome. [G.D.]

**CACALIE E'CARLATE.** (Fr.) *Emilia sonchifolia*.

**CACAO** or **COCOA.** The seeds of *Theobroma Cacao*, which form, or should form, the chief ingredient in chocolate.

**CACHIBOU RESIN.** A gum-resin obtained from *Bursera gummiifera*.

**CACHRYB.** One of the genera of *Umbelliferae* (*Apiaceae*), deriving its name, it is said, from a Greek word indicative of the hot or carminative properties of the fruit. The prominent characteristics of the genus are: the absence of an involucre; the margin of the calyx five-toothed or wanting; entire petals bent inwards at the point: the stylopods or thickened base of the styles not very distinct; the fruit thick and spongy, each half with five thick ribs, and containing several oil channels in its rind. The species are natives of Southern Europe, Siberia, &c. The Cossacks are said to chew the seeds of *C. odontalgica* as a remedy for toothache, the effects being due to the salivation they induce. Several species are in cultivation, but are of no particular interest. [M.T.M.]

**CACTACEÆ.** (*Cacti*; *Cactee*; *Opuntiacese*; *Nopales*; *Indian Figs*.) The cactus family, a natural order of Calycifloral Dicotyledons. They consist of succulent shrubs with remarkable spines clustered on the stems, which are angular two-edged or leafy, and have their woody matter often arranged in a wedge-like manner. Calyx of numerous sepals, combined and epigynous; petals numerous; stamens numerous, with long filaments. Ovary one-celled with parietal placentas; style single; stigmas several. Fruit succulent; seeds without albumen. They are natives of America, whence they have been transported to various quarters of the globe. The fruit of many of the Indian Figs is subacid and

refreshing; in some instances it is sweetish and insipid. The stems of some of the species are eaten by cattle. These stems present very varied forms; some are spherical, others jointed, others have the form of a tall upright polygonal column. Their succulent character enables them to thrive in arid climates, and some of them have been called vegetable fountains in the desert. A South American species, *Cereus peruvianus*, has stems thirty to fifty feet high, and one to two feet in diameter; *C. Thurberi* has a stem ten to fifteen feet high, and *C. Schottii* has one eight to ten feet in height. The spines and bristles on a specimen of *Echinocactus platyceras* were reckoned at 51,000, those of a *Pilocereus sentis* at 72,000. *Opuntia vulgaris*, the common Prickly Pear, has an edible fruit, and *O. cochinellifera*, the Nopal plant, supplies food to the cochineal insect (*Coccus Cacti*). The number of known genera is eighteen, and of species about 800. Illustrative genera: *Cactus* or *Cereus*, *Melocactus*, *Mammillaria*, *Opuntia*, *Pereskia*. [J.H.B.]

**CACTUS.** This name includes in popular estimation all the various species referred by botanists to *Cereus*, *Epiphyllum*, *Echinocactus*, *Echinopsis*, *Mammillaria*, and *Melocactus*; under which genera their several peculiarities will be noticed. It is this old familiar name, sometimes still used under the plural form of *Cacti*, which has given the title of *Cactaceae* to the family to which these plants belong. [T.M.]

**CACTUS, HEDGEHOG.** *Echinocactus*. —, **J.EAF.** *Epiphyllum*. —, **MELON-THISTLE.** *Melocactus*. —, **NIPPLE.** *Mammillaria*.

**CADABA.** A name applied to a genus of *Capparidaceae*, characterised by a calyx of four sepals, distinct or coherent at the base only; petals sometimes wanting; stamens more or less united below; fruit berry-like, stalked, subtended by a strap-shaped nectary. The plants are natives of Africa, India, and Australia. The root of *C. indica* is said to be aperient and anthelmintic. [M.T.M.]

**CADE.** (Fr.) *Juniperus Oxycedrus*.

**CADEN.** An Indian name for *Phanera sylvestris*.

**CADETIA.** A little-known genus of one-leaved epiphytal Orchids with the habit of *Pleurothallis*. Five species are described from the Moluccas and New Guinea. The genus is hardly distinct from *Dendrobium*.

**CADJII GUM.** A South American gum obtained from *Anacardium occidentale*.

**CADUCOUS.** Dropping off.

**CAENOPTERIS.** A name which has been sometimes adopted for the *Dereæ* section of *Asplenium*: a group of species usually distinguishable by the unisporiferous ultimate segments of their fronds. The name has also been given to another fern, now referred to *Onychium*. [T.M.]

**CAEOMACEI.** A term applied to those species of truly parasitic *Fungi* known

familially under the name of Rust and Mildew, which have naked spores free from dissepiments. They are, however, so closely connected with those with septate spores that it is far more natural to unite them. We accordingly refer for further information to the article *Puccinias*. [M. J. B.]

**CÆRULEUS** or **CÆRULEUS**. Blue; a pale indigo colour.

**CÆSALPINIA**. A genus of Leguminous plants typical of the section *Cæsalphinea*, containing about fifty species, most of which are small trees or large shrubs, inhabiting tropical countries. Their leaves are compound, being what is termed bipinnatifid. Their flowers are produced in racemes, and have a top-shaped calyx, divided at the end into five parts, the lowest of which is larger than the others; five unequal stalked petals, the upper one shorter than the rest; ten stamens, and a long slender style.

*C. coriaria* is a small tree twenty or thirty feet high, native of several of the West Indian Islands, Mexico, Venezuela, and North Brazil. The primary divisions of its leaves vary from nine to fifteen, each bearing from sixteen to twenty-four narrow oblong blunt leaflets, marked with black dots on the under surface. It has branched racemes of white flowers, which produce curiously flattened pods, about two inches long by three-fourths broad, and curved so as to bear some resemblance to the letter S. The large per centage of tannin in these pods renders them exceedingly valuable for tanning purposes: they are known in commerce under the names of Divi-divi, Libi-divi, or Libi-dibi, and are chiefly imported from Maracaibo, Paria, and St. Domingo.

*C. cristata*, a native of the West Indian Islands, grows about twenty feet high, and has smooth prickly branches, and leaves with eight primary divisions, each having from three to five pairs of leaflets, which are generally notched at the top, and of an oblong shape, rather broader at the top end. The flowers are yellowish-red, and produce scimitar-shaped pods about three inches long, containing eight or ten seeds. *C. echinata* is a Brazilian tree with prickly branches, elliptical blunt-pointed leaflets and yellow flowers producing spiny pods. The woods known in commerce as Brazil, Pernambuco, Nicaragua, Lima, and Peach-woods, are said to be produced by this genus, but nothing certain is known upon the subject. They are generally attributed to the two last-named species, and to another called *C. brasiliensis* (the correct name of which is *Peltophorum Linnei*), but which is not a native of Brazil. They are all exceedingly valuable to the dyer, producing various tints of red, orange, and peach-colour. The imports of Brazil-wood in 1856 amounted to 1,052 tons, and of Nicaragua-wood to 4,767 tons, the aggregate value of which was 153,637*l*.

*C. Sappan*, an East Indian tree growing about thirty or forty feet high, has

prickly branches, the primary divisions of the leaves varying from twenty to twenty four, and having ten or twelve pairs of obliquely oval-shaped leaflets, notched at the tip, with minute dots on the under surface. The brownish-red wood of this tree furnishes the Sappan-wood of commerce, the Bukkum or Wukkum of India, from which dyers obtain a red colour, principally used for dyeing cotton goods. Its root also affords an orange-yellow dye. In 1858, 4,116 tons of Sappan-wood were imported into this country.

Of other useful species *C. Pipai* produces pods which possess some astringency, and are called Pipi pods; the seeds of *C. digyna*, an East Indian climber, yield an oil used for burning in lamps in India; the roots of *C. Auga* are diuretic; and in China the pods of several species are called Soap pods from their being commonly employed for producing a lather as a substitute for manufactured soap.

[A. S.]

**CÆSAREA**. A genus of *Vivianiaceæ*, containing but few species, all of them natives of Southern Brazil. They are slender herbs one to three feet high, with opposite, or, towards the base of the stem, verticillate leaves, having serrate margins, generally smooth above, and covered with white down underneath. The flowers are axillary towards the ends of the branchlets, white, yellow, or of a reddish colour. None of the species are in cultivation, although they would be pretty greenhouse plants. The genus bears the name of Cesar de S. Hilaire, a captain in the French navy, who first introduced the Mocha coffee to Bourbon. [A. A. B.]

**CÆSIA**. A genus of *Liliaceæ*, containing herbs from Australia and Tasmania, with fasciculate roots often with thickened tuberous fibres, grass-like radical leaves, and rather small white or blue flowers in simple or compound racemes. Perianth six-parted, the segments petaloid and spirally twisted after flowering; stamens six, with glabrous filaments; ovary three-celled, with two ovules in each cell; capsule sometimes one-celled; seeds with an appendage at the base. [J. T. S.]

**CÆSIUS**. Lavender colour.

**CÆSPITOSE**. Growing in tufts or patches.

**CÆSULIA**. The only species of this genus, *C. asillaria*, which belongs to the Composite family, grows in moist places in many parts of India, and is a small weed with alternate linear toothed leaves, and what appear to be single sessile flower-heads, but which are in reality a number of flower-heads enclosed in a common involucre, each of them containing only one floret and provided with a two-leaved involucre, the lower part of which at length unites with, and forms part of the achene, the upper portions remaining free and giving the achene an eared appearance. The florets are purple or white. [A. A. B.]

**CAFE' FRANÇAIS.** (Fr.) *Oleer arietinum*. — **MARRON.** The wild Bourbon *Coffea mauritiana*.

**CAFE'IER or CAFFEYER.** The Coffee tree.

**CAFFER-BREAD.** A South African name applied to various species of *Encaphalartos*.

**CAHINCA or CAINCA.** A Brazilian drug obtained from *Chiococca densifolia*.

**CAHOUN NUTS.** The fruits of *Attalea Cohune*, which yield an oil equal to that of the coco-nut.

**CAIANNE.** (Fr.) A kind of olive.

**CAILLEBOTTE.** (Fr.) *Fiburnum Opulus*.

**CAILLELAIT.** (Fr.) *Gallium verum*.

**CATOPHORA.** A genus of *Loasads*, distinguished from its congeners by having on the calyx ten spirally-arranged ribs; the divisions of the corolla notched at the tip or with three teeth; style or appendage on the ovary single, blind at the end, the two pieces approximate. The name appears to be derived from the Greek verbs signifying 'I burn,' and 'I bear,' in allusion to the numerous stinging hairs which produce a burning sensation when they pierce the skin. The species are herbaceous plants, natives of Peru and Chili, of branched and climbing habit, armed with sharp stings. The leaves are opposite, lobed or deeply cut; the flowers solitary from the angles of the leaves or at the ends of the branches.

The plants have the general aspect of *Loasa*, a genus in which some of them were formerly included. One of the most notable is *C. coronata*, discovered by Dr. Gillies on the sides of the Cordillera, between Mendoza and Chile, at an elevation of 8,000 to 11,000 feet. Dr. Gillies observes of it: 'the general aspect of the plant is very peculiar, and on examining its whole economy we are struck with the care taken to protect the flower, and insure impregnation.' It forms a large convex mass, rising one or two feet from the ground; the upper part is composed entirely of a great abundance of dark green leaves, along the margins of which, and protected by them, are arranged the large whitish flowers, forming one or two or more circlets or fillets, giving the whole a very singular and elegant appearance. The corolla, which is contracted towards its mouth, is of considerable size; the transverse section, at the widest part, being in some cases as large as that of a hen's egg. When the capsules are ripe, they are generally prostrate on the ground, the stalk being too weak to support them. [G. D.]

**CAJANUS** (from *Cajang*, the Malayan name for one of the species) is a small genus of Leguminous plants of the section *Papilionaceae*, forming shrubs, with leaves composed of three stalked leaflets, and flowers produced in racemes from the

angles between the leaf-stalks and stems. Their calyx is bell-shaped and cut half-way down into four divisions, the upper of which has two small teeth; their corolla is papilionaceous; and they have ten stamens, nine of which are united together, and the tenth free. The fruit is a pea-like pod, containing many seeds, and having its husk or shell constricted between each seed.

*C. indicus* is a native of the East Indies, but is now naturalised and cultivated in the West Indies, in tropical America and Africa, and in some islands of the Pacific Ocean. There are two varieties, differing only in height and in the colour of their flowers. It is a perennial shrub growing from three to ten feet high, but in places where it is cultivated it is generally treated as an annual, the stems being pulled up and used for firewood as soon as the crop of seeds has been gathered. All parts of the plant are more or less covered with soft silky or velvety hairs. The leaves are composed of three oval-lance-shaped stalked leaflets. The variety *bicolor* generally grows from three to six feet high, and has yellow flowers marked with crimson streaks on the outside; its pods are spotted or marbled with dark lines. It is called the Congo Pea in Jamaica. The variety *stans* is a larger kind, forming bushes twenty feet in circumference, and varying from five to ten feet high; it has pure yellow flowers and uniformly-coloured pods. In Jamaica it is called the No-eye Pea. Both of these varieties are cultivated in various parts of the tropics for the sake of their seeds or pulse. In India the pulse is called Dhal or Dhol, or Urhur, and it forms a large part of the food of all classes of natives, being ranked as third in value among the pulses. In the West Indies they are called Pigeon Peas, being commonly used for feeding pigeons and other birds; besides which they are highly esteemed as an article of human food, the variety called No-eye Pea being considered to be little inferior in a green state to our English peas, and, when dried and split, quite as good. The Congo Pea is harder and coarser, and is only used by negroes, requiring a great deal of boiling. Pea meal of very good quality is prepared from both the varieties in Jamaica. Horses and cattle of various kinds are very fond of the young branches and leaves, either in a fresh or dried state. The late Dr. McFadyen, speaking of this plant, says: 'There are few tropical plants so valuable. It is to be found round every cottage in the island (Jamaica), growing luxuriantly in the parched savannah and mountain declivity, as well as in the more fertile and seasonable districts.' [A. S.]

**CAJUPUTI.** An old synonym of *Melaleuca*, one species of which, *M. Cajuputi*, yields the stimulant oil of cajuput, used in medicine. [T. M.]

**CAKILE.** A sea-side herbaceous plant belonging to the *Cruciferae*, easily distinguished by its oblong deeply-lobed

sessy leaves, which are smooth and of a glaucous hue: by its lilac flowers; and by its spores when matured is

into two cells, the upper containing a single erect seed, the lower a pendulous one. It is known to sea-side visitors by the name of *Sea Rocket*. Closely allied species inhabit the shores of the Mediterranean and the West Indian Islands. They are all annuals. French, *Capselle*. [C. A. J.]

**CALABA TREE.** *Calophyllum Calaba*.

**CALABASH.** *Oreocordia Oryza*, a tropical tree bearing great gourd-like fruits.  
— **SWEET.** *Passeflora maliformis*.

**CALABASH NUTMEG.** *Monodora Myrsinacea*.

**CALABUR TREE.** *Monteggia Calabura*.

**CALADENIA.** A genus of exquisitely beautiful little terrestrial Orchids inhabiting Australasia. They generally produce one grassy leaf, from within which arises a scape bearing a few ringent flowers, covered in various places in a very remarkable manner with glandular hairs, which have suggested the name. In many species the sepals or petals or both are prolonged into long slender tails; in others they have the usual oval outline. The genus is admirably illustrated in *Hooker's Flora Tenuetosa*.

**CALADIUM.** The generic name of certain plants of the *Arum* family, having a hood-like spathe rolled round at the base; a spadix whose upper portion is entirely covered with stamens, but ultimately becomes bare at the extreme top, provided with blunt glands or sterile stamens in the middle, and ovaries beneath; the anthers shield-shaped and one-celled; the ovaries numerous, two-celled, with from two to four ascending ovules in each cell; the fruit a one or two-celled berry, with few seeds. These plants partake of the acrid properties, which pervade the *Araceae*, but, nevertheless, the rootstocks or rhizomes of some of the species are eaten as food in the West Indies, the Sandwich Islands, &c., in consequence of the abundance of starch contained in them, the process of cooking depriving them of their noxious qualities. It is stated that the rootstocks or tubers of *C. pettiatum* were on one occasion mistaken for potatoes on board ship, and were given to some animals with fatal results. The leaves of *C. angustifolium* are boiled and eaten in the West Indies as a vegetable. Both the rhizomes and the leaves of *C. acuminatum* are commonly exposed for sale in the bazaar of Bombay, Faint, &c., and are eaten by the natives. The species are natives of the warmer regions of the globe, where they are cultivated in abundance for the above-named purposes. Several are also grown in hot-houses in this country; and lately several varieties with variegated foliage have been [M. T. M.]

**CALAMAGROSTIS.** A genus of belonging to the tribe grasses, distinguished chiefly by the inflorescence being in branched panicles, and only one flower in the spikelets, or within the glumes, which has long silky hairs at its base; sometimes the rudiment of a second flower is present; glumes nearly equal, keeled and pointed; pales two, small. There are eighty-six species described in *Stendell's Synopsis*. They have an extensive range over the globe. The greater number are, however, natives of rather temperate climates, and some reach the Arctic circle. Three species only are natives of the British Islands, and neither of these of common occurrence; indeed, *C. stricta* is one of the rarest British grasses, and only grows sparingly in a few localities. They are not valuable for agricultural purposes, though very ornamental. [D. M.]

**CALAMBAC.** The commercial name of Aloe-wood, Eagle-wood, or Lign Aloe, which is produced by *Aloxyllum Agallochum*.

**CALAMINT.** (Fr.) *Calamintha* *nalis*.

**CALAMINTHA.** A genus of Labiate flowers which as at present constituted, comprises several plants described in less recent works under the names of *Thymus*, *Actinos*, *Melissa*, and *Olinopodium*. The essential generic characters of *Calamintha* are: 'calyx two-lipped; stamens diverging; upper lip of the corolla nearly flat, tube straight.' *C. Actinos*, or Basil-thyme (formerly called *Thymus Actinos* and *Actinos vulgaris*), is a low somewhat shrubby plant with stems from four to six inches high, small leaves, and rather showy violet-purple flowers, which grow in whorls of six together. The whole plant is fragrant and aromatic, and well deserves its name from the Greek *basilikos*, royal, M, as Gerard tells us, 'the seeds cureth the infirmities of the hart, taketh away sorrowfulness which cometh of melancholie, and maketh a man merrie and glad.' It is most frequently found in chalky or gravelly pastures. *C. officinalis* (L.) *Melissa* (L.) *lamintha*, *C. Nepeta*, and *C. oyd* lamints or 'Excellent Mint,' as their name imports, are herbaceous aromatic herbs to which great medicinal virtues were anciently ascribed. They bear their flowers in stalked tufts which proceed from the axils of the opposite leaves, and are only to be distinguished from one another by a minute comparison of characters. They all possess a strong aromatic odour resembling that of penny-royal, and are employed to make herb-tea. *C. officinalis*, the Wild Basil, formerly *Olinopodium vulgare*, is a straggling hedge plant with hairy stems from one to two feet long, bearing its rather large purple flowers in dense whorls in the axils of the hairy ovate distant leaves, and having numerous bristly bracts at their base. The odour is aromatic, but not so agreeable as in the other species. [C. A. J.]

a. *Artocarpus*  
*incisa*

b. *Caladium*

c. *Pandanus*  
*odoratissimus*  
in fruit

d. *A. crinum*

**CALAMOGAGUE.** The four species constituting this genus of Palms do not possess any individual features of interest beyond their technical characters. They are all natives of the forests of the Malayan peninsula, and have climbing whip-like stems, growing to a great length, and supporting themselves by means of their hooked spines. The footstalks of their pinnate leaves are likewise armed with prickles and hooked spines, and terminate in a long whip-like tail; the leaflets are of a green colour on the upper surface, and covered with a bluish bloom underneath; their top half is broad and very much jagged, the lower half being entire and wedge-shaped. One of the chief characteristics of the genus is the presence of a broad leafy expansion called the ligule, near to and partly surrounding the base of the footstalk of the leaf. They have perfect flowers, arranged in branching spikes resembling bunches of catkins, each flower being half buried in a dense mass of wool, and having a three-toothed calyx, a three-parted corolla, six stamens, and a three-celled ovary covered with scales, and crowned by a three-toothed awl-shaped style. None of the species are known to possess any useful properties, but as their stems bear a close resemblance to some of the species of *Calamus*, they are probably used for similar purposes. One species, *C. harintafolius*, is called Rotang Simote by the Malaysians, and another, *C. ochriger*, Rotang Donam. [A.S.]

#### **CALAMPELIS.** *Eccremocarpus*.

**CALAMUS.** The stems of several species of this genus of Palms are well known in this country under the names of Rattans or Canes. Upwards of eighty species are described, nearly all natives of Asia, abounding in the Malayan Peninsula and Islands, also in the eastern and north-eastern provinces of India; two are found in Australia, and one in Africa. They have reed-like stems, seldom more than an inch or two in thickness, but often much less, generally growing to a great length, climbing over and amongst the branches of trees, and supporting themselves by means of hooked spines attached to their leaf-stalks; a few, however, form low bushes or small trees. Their leaves are pinnate, and in many of the species, the leafstalk is prolonged beyond the termination of the leaflets into a whip-like tail. The flowers are small, generally of a rose or greenish colour, and arranged very close together upon long branching spikes, the ultimate branches somewhat resembling catkins. They have a three-toothed calyx, and a three-parted or three-petaled corolla; the males having six stamens joined together at the base, and the females imperfect stamens, and a three-celled ovary, more or less covered with scales, and bearing three stigmas (no style). The spikes are surrounded by numerous bracts or spathe, which, however, do not completely enclose them, and each branch of the spike has a

separate bract at its base. The fruits are covered with smooth shining scales, which are fixed by their upper edges, and overlap each other from the top downwards, like plates of mail; they generally contain a single seed, surrounded by an eatable pulp.

*C. Rotang*, *C. rudentum*, *C. verus*, *C. viminalis*, and probably several other species, furnish the canes or rattans so commonly employed in this country for the bottoms of chairs, couches, sides of carriages, and similar purposes; and of which no fewer than 18,625,368 were imported in 1866, and valued at 38,960*l*. In the countries where these palms abound, the inhabitants make use of them for a great variety of purposes, baskets of all kinds, mats, hats, and other useful articles being commonly made of them. Their most important use, however, is for the manufacture of the ropes and cables usually employed by junks and other coasting vessels. In the Himalayas they are used in the formation of suspension bridges across rivers, the construction of which Dr. Hooker thus describes: 'Two parallel canes, on the same horizontal plane, were stretched across the stream; from these others hung in loops, and along the loops were laid one or two bamboo stems for flooring; cross pieces below this flooring hung from the two upper canes, which they thus served to keep apart. The traveller grasps one of the canes in either hand, and walks along the loose bamboos laid on the swinging loops.'

*C. Scipionum*, the stems of which are much thicker than those of the preceding, furnishes the well-known Malacca canes so much prized for walking-sticks. They are imported from Singapore and Malacca, but are chiefly produced in Sumatra. Some are of a uniform rich brown colour, whilst others are variously mottled or clouded as it is called; the colour, however, is said to be artificially imparted to them by smoking. *C. Draco*, the species yielding the red resinous substance called dragon's-blood, is now placed in the genus *Demonorops*, as also are several other *Calami*. [A.S.]

**CALAMUS.** A fistular stem without an articulation.

**CALAMUS AROMATICUS.** *Acorus Calamus*. — **ODORATUS.** *Andropogon Schenanthus*.

**CALANDRENIA.** A genus of *Furcraea* consisting of smooth fleshy plants of annual or perennial duration, with entire leaves, and, in the case of the species in cultivation, showy purple or rose-coloured flowers expanding only in sunny weather. It is well distinguished among the other genera of the order by its two persistent sepals, which close over the seed-vessel after the petals have fallen: three to five

or valves, and containing numerous seeds adhering to a central placenta. A few only of the species are introduced, but they include probably the most interesting members of the genus. As a type of one section, reference may be made to the *C. discolor*, which has large oblong or lanceolate pointed glaucous leaves, mostly radical, green on their upper surface and purplish beneath, whence its specific name; and flowers one and a half inch across, of a bright rose colour, produced in a long distant raceme on a sort of scape, the foot-stalks being deflexed before and after flowering, and furnished with one or two ovate bracts at their base; a calyx of two broad concave pieces spotted with black, and petals inversely heart-shaped. The *C. grandiflora* closely resembles it, but has, notwithstanding its name, rather smaller flowers, with leaves which are more tapering at the point and base, and green on both surfaces. Both of these species, though usually treated as annuals, are perennial in warmer latitudes than our own, and are, as well as the following plant, natives of Chili. *C. umbellata* differs very considerably in habit from the two preceding, forming a small spreading tuft with shrubby shoots thickly set with linear foliage, fringed at the margins. The flowers are produced in terminal umbels, more or less compound, according to the strength of the plant, each blossom being about half an inch in diameter, and of a rich purple-crimson colour. Possessing a harder constitution than the foregoing plants, it frequently endures our winters in dry soils, though often treated as an annual. *C. speciosa*, a Californian annual, is of procumbent habit with numerous branched stems radiating from the crown of the root, thickly clothed with narrow spatulate glossy leaves, and producing singly from its axils a profusion of crimson purple flowers rather larger than in *umbellata*. The seeds of this species are lenticular in form, and of a glossy black colour, by which they are readily distinguishable from those of the three previously-named. There is a variety of this with flowers of a coppery-red colour. [W. T.]

**CALANTHE.** A large genus of terrestrial stemless vandevoe Orchids with broad many-ribbed leaves, and long spikes of flowers, the lip of which is calcarate and adherent to the column, while the waxy pollen masses are eight, adhering to a separable gland. Some thirty species are known, chiefly from tropical and extratropical Asia; a few are American. The flowers, which are white, or lilac, or purple, or copper-coloured, are ornamental, wherefore several species are in gardens. Of these *C. vestita* is one of the handsomest.

**CALATHEA.** A genus of *Marantaceae*, deriving its name from its cup-shaped stigma. These plants have large leaves springing from the contracted stem near the root, from which they appear directly to emerge. The flowers are in terminal

spikes and protected by bracts; they have a calyx of three segments; a corolla of six pieces, the external ones lance-shaped, the internal ones blunt and irregular in shape; three petal-like stamens, one of which bears a linear one-celled anther, attached to its edge, while the rest are sterile; and a petal-like style, the stigma hooded, angular. The species are natives of tropical America, and some of them are in cultivation for the sake of their handsome foliage, especially *C. zebrina*, the leaves of which have alternate dark-coloured and green stripes. The leaves of some of the South American kinds are used for making baskets. [M. T. M.]

**CALATHIAN VIOLET.** *Gentiana Pneumonanthe*.

**CALATHIDA, CALATHUS, CALATHIDIUM.** The head of flowers borne by Composites.

**CALATHIFORM.** Cup-shaped, or almost hemispherical.

**CALATHODES.** A genus of *Ranunculaceae* containing one species, *C. palmata*, from Sikkim, growing at an altitude of about 10,000 feet. A perennial herb with the habit of *Trollius*, having palmately cleft leaves, a simple stem one and a-half foot to two feet high; flowers large terminal and solitary, with five ovate acute petaloid sepals; petals none; ovaries ten or more, oblong, gibbous externally, beaked; ovules eight or ten; style bent down outwards after flowering. [J. T. S.]

**CALAVANCE.** A name for several kinds of Pulse, including *Dolichos barbadensis* and *D. sinensis*.

**CALBOA.** A synonym of *Quamoclit*.

**CALCAR** (ad). *Calcaratus*. A spur; hollow process of some part of a flower.

**CALCAREOUS.** Dead-white, like chalk. Also growing in chalky places, or having the substance of chalk.

**CALCARIFORM.** Shaped like a calcar or spur.

**CALCEARIA.** *Coryanthos*.

**CALCEOLARIA.** A beautiful genus of *Scrophulariaceae*, distinguished chiefly by the peculiar form of the corolla, which has two lips, the lower of which is inflated, somewhat elongated and turned downwards, having some resemblance to a shoe; the stamens are two in number. The name is derived from the Latin word 'Calceolarius,' a shoemaker. The peculiar form of the corolla, above described, is nevertheless not invariably a character of the genus; the plant known in collections as *C. violacea*, a native of Chili, has the corolla in the form of two equal gaping lips; it was formerly placed in the genus *Josellana*, but is now considered by the best authorities as a true *Calceolaria*. The numerous species of this favourite and well-known genus are either herbaceous or shrubby in habit, with leaves in pairs or three to

gether, rarely alternate, either entire toothed or deeply cut, often more or less hairy, the flowers variously grouped and distributed, the prevailing colours, yellow white or purple. They are natives of South America, confined either to the western side of the Andes, or to the southern extremity of the mainland and the adjacent islands. Some are found only near the level of the sea, and others are inhabitants of the higher parts of the Cordilleras; hence it is that, among the numerous introduced species in our collections, a few are more or less hardy, others require protection. *C. floribunda*, for instance, is a native of the vicinity of the city of Quito, at an elevation of 11,000 feet above the level of the sea, and several occur at low altitudes in the Falkland Islands, &c., forming a prominent feature of the native vegetation. In the *Flora Antartica*, Dr. Hooker thus alludes to the *C. Polakowskii* of Port Famine: 'Though inferior in stature and beauty to many of its congeners, this is among the prettiest of the wild flowers of the Falklands, and the attention of the voyager who is familiar with the genus *Calceolaria* only in the conservatories of Britain, must be attracted by its appearance on the exposed shores of these inhospitable islands.' Many of the original pure species have been modified by hybridising, and are not now so common in collections. The hybrids are numerous and some of them greatly prized; not only is the size of the flower modified but the colour as well, the shades of yellow and purple being highly varied, as also the characters of the spots on the slipper-like portion. The handsome aspect of different species and crosses has always recommended them to the attention of cultivators, and acted as a stimulus to the exercise of ingenuity in discovering the proper method of treatment. The results have been such, that on plants attaining a height of two feet or little more, the flowers may sometimes be counted by hundreds, expanded about the same time. [G. D.]

**CALCEOLATE.** Having the form of a slipper or round-toed shoe.

**CALCEOUS.** Dead-white, like chalk.

**CALCITRAPA.** The Star Thistle, *Centaurus Calcitrapa*.

**CALDASIA.** A genus of *Polemoniaceae*, containing annual herbs from Mexico with glandular hairs, branched stems, and alternate crenate-serrate leaves. Peduncles axillary, in pairs, one-flowered; calyx five-sided, five-toothed at apex, scarious in fruit; corolla violet blue, funnel-shaped, with a five-parted limb, the lobes notched at the apex, and two of them apart from the other three; stamens five, protruding, bent down; capsule three-celled; seeds in each cell with a spongy coat. [J. T. B.]

**CALDOLUYIA.** A genus of *Osmontaceae*, containing a small tree from Chili, with opposite simple lanceolate serrated leathery

leaves, glaucous below; stipules lanceolate, deciduous; flowers in axillary panicles; calyx deciduous, four or five parted; petals four or five, inserted on a disk which has as many glandular notched lobes as there are petals; stamens eight or ten, inserted within the disk; ovary free, two or three-celled; ovules numerous; styles two or three, becoming reflexed. [J. T. B.]

**CALEA.** The species of this genus, which belongs to the Composite family, are natives of tropical America, extending from Mexico to South Brazil. They are herbs or small shrubs with opposite or whorled entire or toothed leaves, generally three-nerved and very rough on the surface, many of them resembling those of the common nettle in form. In one group the species are dwarf and unbranched, bearing a long-stalked terminal flower-head, about an inch in diameter, containing both strap-shaped and tubular florets, the former having pistil only, the latter both stamens and pistil. In another group the plants are larger, the flower-heads small and numerous, disposed in corymbs at the ends of the branches, and bearing tubular florets only. The flowers of most of them are yellow and the pappus is made up of from five to twenty lanceolate pointed scales. Upwards of thirty species are known. *C. Zacatechichi*, a Mexican species with nettle-like leaves and small flower-heads, is known there by the name of 'Jurallilo,' and is said to contain, in a fresh state, a considerable quantity of camphor, and to be employed against fevers, and the powdered leaves for healing wounds. The leaves of *C. jamaicensis* are said to be powerfully bitter, and steeped in wine or brandy are used as a stomachic in the West Indies; but this account is thought to apply rather to *Neurolema lobata*. [A. A. B.]

**CALEANA.** A few brown-flowered terrestrial Orchids confined to New Holland bear this name. They have simple filiform roots terminated by a small tubercle, solitary radical leaves, and a slender few-flowered scape. The column is broad, thin, and concave; the sepals and petals narrow and reflexed; the lip posticous, peltate, unguiculate, and highly irritable. In fine weather or when undisturbed, this lip bends back and leaves the column uncovered; but if it rains or the plant is jarred, down goes the lip over the column, which it securely boxes up. See *DRAKÆA* and *SPICULÆA*, in which a similar phenomenon occurs.

**CALEBASSE.** (Fr.) The Bottle Gourd, *Lagenaria vulgaris*.

**CALEBASSIER.** (Fr.) The Calabash tree, *Crescentia Cujete*.

**CALECTASIA.** A genus of *Juncaceae* containing a small branched shrubby plant from South Australia, with needle-shaped leaves sheathing at the base, and solitary flowers on short terminal branches, having a salver-shaped perianth with a six-parted limb of petaloid blue segments

spreading like a star, the three outer pubescent; stamens six. The ovary is one-celled with three ovules. [J. T. S.]

**CALEE KUSTOOREE.** An Indian name for the Musk Ochro, *Abelmoschus moschatus*.

**CALELYNA.** A section of *Evolvina*.

**CALENDULA.** The name of a genus belonging to the Composite order, having numerous flowers grouped on a nearly flat surface, those at the circumference strap-like, in two or three rows and with pistils only, those in the centre tubular with stamens only, both kinds hairy at the base, the whole surrounded on the outside by a series of scale-like leaflets. The name *Calendula* is founded on the circumstance that species may be in flower on the calends of every month. They are annual or perennial, chiefly natives of the Mediterranean borders, with yellow or orange-yellow flowers, usually of a powerful, not pleasant odour. One of them, *C. officinalis*, the Pot Marigold, formerly enjoyed repute as a domestic remedy, being used in forming a distilled water or vinegar. [G. D.]

**CALF'S SNOUT.** *Antirrhinum Oronotum*.

**CALICATE.** Furnished with a calyx.

**CALICINAR.** When a flower becomes double by an increase in the number of lobes of the calyx or sepals.

**CALICIUM, CALICIEL.** A genus and family of Lichens known at once by the sporidia forming ultimately a dusty stratum over a little orbicular disc which is either nearly sessile or supported upon a short stalk so as to look like a little nail more or less completely driven home. The sporidia, as in other lichens, are at first contained in asci, which soon, however, disappear. One of the most familiar species is *C. inquinans*, which is common upon gate-posts, and attracts notice from leaving the print of its discs upon the finger when touched. The crust is sometimes very obscure or almost obsolete. All the species of *Calicium* are, we believe, found in Europe, though several of them occur elsewhere. [M. J. B.]

**CALICO BUSH.** *Kalmia latifolia*.

**CALICULAR.** A term of estimation, when the outer bracts of an involucre are much shorter than the inner.

**CALIMERIS.** The generic name of plants belonging to the Composite order, having the flowers in heads, those at the circumference in one row, strap-like, the heads surrounded externally by two to four rows of nearly equal scale-like leaves. The surface supporting the flowers has numerous four-cornered pits or depressions toothed at the angles. The fruit is flat and hairy. The name *Calimeris* is of Greek derivation, and indicates general beauty of parts. The species are perennial herbs, natives of middle and Northern

Asia, with the leaves entire or toothed and cut at the margin; the heads of flowers yellow in the middle, and white or blue at the circumference. [G. D.]

**CALIPHRURIA.** A genus of *Amaryllidæ*, forming a link between *Euryclæ* and *Griginta*, and having, except in the inflorescence, much the appearance of *Eucrodia*. The species, *C. Hartwegiana*, has ovate bulbs, petiolate depressed perennial oval acuminate somewhat plaited leaves, with a blade six inches long or more, a glaucous scape a foot high bearing an umbel of about seven subdeclinate flowers, having a green tube and white limb. The tube of the perianth is narrowly funnel-shaped and nearly straight, the limb regular with the segments turned back in the form of a star, the sepaline ones rather the broader. The filaments of the six stamens are inserted at the base of the segments of the perianth, and have a white bristle on each side, and they are associated with a straight style terminated by a somewhat recurved three-lobed stigma. *C. Hartwegiana* is a native of New Grenada. [T. M.]

**CALLA.** A genus of *Orontiaceæ*, consisting of herbaceous marsh plants with creeping or floating stems, heart-shaped entire leaves, the stalks of which emerge from a sheath. The flowers cover a spadix, which is protected by a flat spathe, the flowers themselves having neither calyx nor corolla. The upper flowers are female, consisting of a one-celled ovary, from the base of which arise the ovules; the lower flowers are hermaphrodite with numerous thread-shaped stamens, flattened and dilated at the top, and springing from below the ovary. The species are natives of Northern Europe and North America, and possess acrid caustic properties. The rootstocks of *C. palustris* yield eatable starch, prepared by drying and grinding them, and then heating the powder till the acrid properties are dissipated. [M. T. M.]

**CALLA D'ETHIOPIE.** (Fr.) *Richardia æthiopica*.

**CALLCEDRA-WOOD.** The timber of *Mindorta australis*.

**CALLERYA.** The name formerly given to a plant of the Leguminous family, but now found to be a species of *Milletia*, and perhaps the same as *M. nitida*, which is, like this, a native of NE. China. It is a small tree, with alternate unequally pinnate leaves, about a foot long, with two pairs of ovate leaflets from one to three inches in length; numerous flowers in terminal panicles; and two-valved pods one to three inches long, containing one to five seeds, covered externally with a velvety pubescence. [A. A. B.]

**CALLIANDRA.** A beautiful genus of Leguminous plants peculiar to America, found as far north as California, and extending southwards to Buenos Ayres. A few are herbs not more than a foot high, but the greater portion shrubs or small

trees, most frequently met with on river banks. The leaves of all are bipinnate, the leaflets varying much in size and number. In one section the leaves have one to four pairs of pinnae, with few but large leaflets (one to eight inches long), the ultimate ones always the largest; while in another there are many pairs of pinnae, the leaflets scarcely half an inch long, linear in form and almost numberless. The flowers are usually borne on stalked globose heads, but sometimes in terminal racemes; the corollas small and hidden by the very numerous long filaments of the stamens, which are almost always of a beautiful red colour. From this latter circumstance the genus is named *Calliandra*, signifying 'beautiful stamened.' It differs from all allied genera in the valves of its compressed pod rolling backwards in a remarkable manner from apex to base when the seeds are ripe. Many of the species are in cultivation in plant-stoves, and almost all of them produce bright red balls of flowers, which stand erect from amongst the ferny foliage of some of the species in great profusion. In *C. diademata* the stamens are beautifully curved backwards and pink in colour; the leaves twice pinnate with eight or nine pinnae which have each from thirty to forty leaflets, so that

*Calliandra Tweedii*.

each leaf is made up of no fewer than six or eight hundred leaflets. This is a native of Brazil, and in cultivation. *C. hama-topheala*, a lately introduced species, has binate leaves, each portion or pinna with about ten pairs of leaflets half an inch long, and its round balls of flowers are of a rich red colour. The Peruvian women decorate their hair with the flowers of *C. atrovirens*, calling them *seda-stas* or Silk-flowers. More than eighty species are enumerated, all of them more or less orna-

[A. A. B.]

**CALLICARPA.** A considerable genus of *Verbenaceae*, chiefly from the tropical and subtropical districts of Asia, but found also, though more sparingly, in similar districts in Africa and America. They are shrubs, more or less woolly with stellate hairs, nearly glabrous, and often with numerous resinous glandular dots, especially on the under surface of the leaves. The flowers are small in axillary cymes. The calyx is truncate or four-toothed; the corolla tube is short, and the limb has four nearly regular lobes. There are four exserted stamens, a four-celled ovary, with a single ovule in each cell; and the fruit is a small juicy berry or drupe, with four distinct seed-like nuts or kernels. [W. C.]

**CALLICOMA.** A genus of *Omniosaceae*, containing small trees or shrubs from South Australia, with opposite simple lanceolate leaves, white beneath, furnished with elliptical membranous caducous stipules. The peduncles are long, axillary, with a dense globular head of small yellow flowers, which are sessile on a woolly receptacle, and surrounded by a four-leaved reflexed involucre. Flowers with four or six membranous bracts forming an involucre; calyx-tube very short, scarcely adhering to the ovary at the base; the limb four or five parted, persistent; corolla absent; stamens eight or ten; ovary woolly, two-celled, many-ovuled, the styles two, diverging. [J. T. B.]

**CALLIGLOSSA.** *C. Douglasi* is a pretty little yellow-flowered Californian annual of the Composite family, with few strap-shaped leaves, toothed at the apex, about half an inch long and very narrow. The yellow flower-heads are single at the ends of the branchlets. Being a very free flowerer, it is often used as a bedding plant in flower gardens, and, like many of our best annuals, was introduced by Mr. Douglas. The genus does not differ from *Callichroa*, and the plant is therefore generally called *Callichroa Douglasi*. [A. A. B.]

**CALLIGONUM.** A genus of shrubs belonging to *Polygonaceae*, natives of the Eastern Mediterranean region, and Central Asia. They are leafless plants with dichotomous jointed branches, each joint with a small membranous sheath at the base. Flowers small, on short-jointed pedicels springing from the axils of the sheaths; perianth coloured red, five-parted, reflexed in fruit, the two outer segments larger. The fruit is a large four-cornered nut with the corners expanded into double longitudinal spinous wings, the sides between the wings being covered with long branched shaggy filaments. [J. T. B.]

**CALLILEPIS.** A small genus of *SB*, African plants belonging to the Composite family. They are herbs, about a foot high, branching from the base, or simple, with lanceolate entire or slightly serrated leaves, which are opposite on the lower part of the stem, and alternate above. The flower-heads single and terminal, nearly an inch

in diameter, with strap-shaped ray florets bearing a pistil only, and tubular disc florets bearing both stamens and pistil. The pappus is made up of three unequal scales. The flowers are yellow. [A. A. B.]

**CALLIOPSIS.** A genus of plants belonging to the Composite order, distinguished from their allies by the involucre or covering which surrounds the heads of the flowers being formed of two rows of scales, the outer short and spreading, the inner larger erect and united at the base. The receptacle or part supporting the flowers is flat, having on it narrow scales which fall early and are shorter than the flowers. The fruit is truncated, incurved, destitute of appendages. The name is from two Greek words which together signify 'beautiful eye, aspect, or appearance.' In allusion to the general elegance of the species or the eye-like spot on the flowers. The genus comprehends a number of interesting herbaceous plants, natives of North America, several of which were, and indeed still are, referred by some authorities to the genus *Coreopsis*. They are usually free from hairs, the leaves opposite, more or less divided; the flowers at the circumference of the heads yellow, with a dark purple or rose-coloured spot at the base, those in the centre yellow or purple. The elegance of the flowers, so marked in these plants, renders them desirable in flower-beds. The more hardy species, whether annual or perennial, are generally of easy cultivation. *C. rosea* has been long known, and may be specially alluded to as an example of the genus; having the stem smooth, leaves opposite, long and narrow, the heads of flowers small on short stalks. [G. D.]

**CALLIPELTIS.** An annual erect much-branched slender herb belonging to the order *Rubiaceae*. The flowers grow in whorls of six, and are whitish four-parted and bell-shaped. The fruit, which is one-seeded by abortion, is partially enveloped by a large hollow membranous bract. The leaves and leaf-like stipules form whorls of four. *C. cucullaria*, the only species, a native of the Levant, is an unimportant plant growing from six to twelve inches high. [C. A. J.]

**CALLIPHYSA:** A genus of *Polygonaceae*, differing from *Calligonum* only by having the nut not winged at the angles but rounded, and covered with bristles, and expanded at the apex into a bladder-like envelope to the nut. [J. T. S.]

**CALLIPHYRA.** A genus of *Ullaceae* plants, found in California, and consisting of dwarf bulbous herbs with small radical linear-ensiform leaves, and bearing the flowers in umbels at the top of a scape. The perianth is bell-shaped, six-parted, with equal-spreading segments; it is furnished with six stamens, all perfect, with petaloid bilobed filaments, the alternate ones shorter, and the anthers sessile between the lobes; and it has a stalked three-

celled ovary containing many ovules, and surmounted by a three-lobed stigma. *C. lutea*, the only species, is a dwarf plant, producing umbels of yellow star-shaped flowers resembling those of an *Ornithogalum*. [T. M.]

**CALLIPSYCHE.** A genus of *Amaryllidaceae*, founded on a Mexican species allied to *Eucrosia*, and named *C. enerosioides*. The plant has roundish bulbs, furnished with a few green tessellated and pitted leaves, a foot long and four inches wide, and produces at a different season, before the leaves are developed, a glaucous scape upwards of two feet high, bearing an umbel of declinate flowers, which are stalked. The perianth consists of a short green tube, full of honey, and an erect regular limb nearly an inch long of bright red segments, the sepaline of which are boat-shaped, and the petaline obtuse. The six stamens are pale green, and with the style are about four times as long as the perianth. The filaments are free, inserted in the mouth of the tube, and are tuberculate at the base. In our gardens the leaves die away in the autumn, and the flower-scapes appear in spring before they are again developed. [T. M.]

**CALLIPTERIS.** A genus of polypodiaceous ferns of the group *Aspleniceae*. They belong to the diplazoid series, having the sori more or less abundantly and constantly placed in pairs back to back on the same vein; and are specially distinguished in the typical group by having the veins joined together in a connivent manner, that is, the main veins that spring out from the midrib are parallel, and the venulae which branch out from them set off at an angle and meet the opposite ones in the centre, and so form a series of acute angles one above the other. In one group the junction of the veins is less regular and frequent. The species, ten or twelve in number, are almost all found in the eastern tropics, but one or two occur in the W. Indies and S. America. They are generally large growing plants with coarse pinnated or twice or thrice-pinnated fronds, the rachis sometimes proliferous. [T. M.]

**CALLIRHÖE.** A genus of beautiful North American Mallow-worts, comprising several perennial herbaceous species, sometimes known by the name of *Nuttallia*, which, however, belongs to a genus of *Rosaceae*. They are very nearly allied to *Malva* itself, from which they differ in certain slight technical peculiarities of the fruit; and also in some of the species, by wanting the involucre or whorl of bracts which is found exterior to the calyx in many of the genera of this order. The involucre, when present, consists of from one to three bracts, which are sometimes remote from the flowers. The calyx is five-cleft; the corolla five-petaled, the petals truncate wedge-shaped, and often coarsely-toothed at the tip. The filaments of the stamens are united into a columnar tube which bears a tuft of many stamens

at the end. The carpels are numerous, united by a short beak, and are one-seeded. About half-a-dozen species are recorded, and some of them are known in cultivation. *C. digitata*, which is one of the original typical species, has no involucre beneath the flowers. It is an herbaceous perennial, with palmately five-parted root-leaves, having lobed or toothed segments, and a smooth slender branching stem two to two and a half feet high, producing a few leaves towards the base, but leafless above, and producing the flowers in corymbosely racemose heads. The flowers are five-petaled, a couple of inches across, the petals imbricately toothed at the truncate apex, and bearded at the base, of a rich dark crimson-purple, and very handsome. This plant is sometimes called *Nuttallia grandiflora*. *C. Papaver*, another species of the genus, a good deal resembles *digitata*, but this is furnished with a three-leaved involucre. It has five-lobed leaves with lobate segments and large solitary long-stalked flowers from the upper axis, these being of a rich bright rosy-lake colour, and very showy. The name *Callirhoe* has also been given by Link, to a group synonymous with *Amaryllis*. [T. M.]

**CALLISIA.** A genus of the order of Spiderworts, distinguished by three stamens having their filaments or supports bearded, and in the form of a flat circular surface at the top; the style or appendage on the top of the fruit thread-like and ending in three points. The name is derived from the Greek, and indicates the beautiful or handsome aspect of the species, which are natives of the warmer parts of America, having stems trailing at the base, the leaves sheathing the stem, their general outline lance-shaped, often with hard projections at the margin. *C. repens*, a native of the West Indies, is one long known in cultivation; its graceful habit, and brilliant leaves with purple edges are sufficient recommendations. [G. D.]

**CALLISTACHYS.** A genus of pretty Australian plants belonging to the Leguminous family, and having alternate stalked entire smooth or silky leaves, and long racemes of yellow or purple flowers. The stalked pods are divided when young into as many partitions as there are seeds, but these divisions are obliterated as the pod ripens. The generic name is derived from the Greek, and signifies 'beautiful spike.' A number of the species are in cultivation in greenhouses. *C. lanceolata* has racemes of golden yellow flowers, nearly as large as those of the broom, and the stems and leaves are covered with beautiful silky hairs. *C. linearis* has dull purple flowers, while *C. longifolia* has racemes of yellow flowers with a purple keel. The species with one exception, *C. sparsa*, which is found in N.S. Wales, are all natives of the Swan River colony. [A. A. B.]

**CALLISTEMON.** A name indicative of the beauty of the stamens in the genus of *Myrtaceæ* to which it is given. The calyx

tube is hemispherical, while the limb is divided into five obtuse lobes; petals five; stamens numerous, of considerable length, and not united together; style thread-like; capsule with three many-seeded compartments, included within the hardened tube of the calyx. These handsome flowering trees or shrubs are natives of Australia. *C. salignum* has much the appearance of the common weeping willow. The young foliage of some of the kinds is of a pink colour, so that the trees when putting forth their leaves appear from a distance to be in blossom. The outer bark of some of the kinds, according to Dr. Bennett, peels off in layers, hence the trees are called Paper Bark trees. Many of the kinds are grown in this country for their handsome flowers. [M. T. M.]

**CALLISTEPHUS.** The generic name of plants belonging to the Composite order, the distinguishing characters of which are the following: the involucre or part surrounding the heads of flowers consists of three or four series of spreading scales fringed at the edge; the receptacle or surface which supports the flowers is somewhat convex and slightly pitted; the fruit compressed, thickest above, its pappus or crown in two rows, the outer of partially united bristles, the inner of longer rough hairs. The name is derived from two Greek words, which together signify 'beautiful crown,' in allusion to the appendages on the ripe fruit. The genus was originally founded on the characters of a plant long known as *Aster stensis*. The species are annuals, chiefly natives of China; they have erect branched stems, with stalkless alternate and toothed leaves, the branches with single heads of flowers. The one already alluded to as *Aster stensis*, and a very general favourite with cultivators, has the individual florets either strap-shaped or tubular, and presenting various tints of rose, violet and white; it is the 'Reine Marguerite' of gardeners. It has these recommendations: it is hardy, of easy cultivation, and flowers freely for weeks in succession; it is therefore a desirable plant in flower-beds. [G. D.]

**CALLISTHENE.** A genus of the *Vochisia* family, found in Brazil, and composed of a few somewhat resinous opposite-leaved trees, which differ from the others in the family in the following combined characters: the five-parted unequal calyx, the upper and larger segment of which is prolonged behind into a spur; the single inversely heart-shaped and stalked petal; and the solitary stamen whose anther is four-celled. The leaves are either smooth or downy, and have entire margins; in one species they are oval and about two inches long, while in another they are linear and scarcely half an inch in length. The yellow flowers (about the size of those of a pea) are either single or numerous in the axils of the leaves, and, like all the others of the family, are remarkable for the unsymmetrical arrangement of their parts. We have first an irregularly five-parted

calyx, one of whose divisions is prolonged into a spur somewhat like that in a bell-shaped flower; then comes a single yellow striped petal, instead of five, as would generally be the case; next a solitary stamen; and lastly a three-celled ovary, which, when mature, becomes a woody capsule about the size of a hazel-nut, containing a number of seeds, and splitting into three portions. [A. A. B.]

**CALLITHAMNION.** A beautiful genus belonging to the division *Ceramiales* of the rose-spored *Algae*, to which it bears nearly the same relation as *Cladophora* does to the chlorosperms. The frond is generally more or less branched, and often most beautifully pinnate, consisting of jointed threads, the stem alone being occasionally slightly compound from decurrent branchlets, as in *Batrachospermum*. The tetraspores and capsules often occur on different plants, the latter containing irregularly distributed spores. Antheridia again are mostly produced on distinct plants. The species are extremely numerous and occur in most parts of the world on other algae, and on almost any object which is washed by the waves. One or two species are found on rocks only occasionally immersed. From their beautiful ramification these plants are the delight of wanderers on the sea-shore, and afford great gratification to those who possess only imperfect microscopes. [M. J. B.]

**CALLITHAUMA.** A genus of Peruvian *Amaryllidaceae* related to *Pancratium*, and remarkable for the large size of the staminal cup or coronet of its perianth, which is equal to that of the limb. *C. viridiflorum* has large oblong-cylindrical bulbs, long flat ensiform suberect leaves, and a flower scape, which is said sometimes to reach six feet in height in its native country, supporting four or five emerald green flowers, which have a horizontal slender tube two inches long, acuminate spreading limb segments; and a large cup or coronet. Mr. Mathews found this with scapes three feet high growing in dryish exposed situations. The other species, *C. angustifolium*, is similar in character, but rather smaller. [T. M.]

**CALLITRICHE, CALLITRICHACEÆ.** A small aquatic plant with simple entire opposite leaves and minute unisexual axillary flowers, so reduced in structure as to afford little indication of its real affinities, and to have induced botanists to propose it as a distinct family, under the plural name of *Callitrichaceae*. The male flowers consist of a single stamen, between two small bracts; the females have a six-lobed four-celled ovary and fruit, crowned by two styles without any perianth, each cell enclosing one pendulous ovule and seed. The genus has been most frequently associated with other minute-flowered aquatic plants, under *Haloragaceae*, but, more recently, it has been proposed, upon more plausible grounds, to

consider it as a much-reduced aquatic form of *Caryophyllaceae* or *Elatinaceae*.

*C. aquatica* is common in our ponds and still waters, often floating over them in large masses, and it is found in most parts of the world. It varies much in its leaves, either all narrow and submerged, or more frequently the upper floating ones, oblong or obovate, in the size and form of the fruits, the erect or recurved styles, &c.; and it has been, therefore, variously divided into from two to twenty supposed species, which are now more generally admitted to be varieties of a single one.

This apetalous genus, which is singular in its structure, consists of small herbaceous plants, natives of Europe and North America, growing in ponds and streamlets, usually immersed, but becoming more luxuriant in habit and producing much more seed when growing out of the water. The most common form in the British Islands is that called *C. verna*. The axillary flowers are usually unisexual, the males and females growing on the same plants; but not unfrequently they become hermaphrodite, apparently from the male flowers producing ovaries. The male flower consists of but one stamen without a calyx, its only envelope being two lateral bracts, which are in some species wanting; and the anther is two-celled, or more commonly one-celled, from the two cells having become confluent. The female consists of a four-celled ovary having but two stigmas, and is elevated on a short stalk, and enveloped by two lateral bracts as in the male. The cells contain one ovule each, suspended from the side, and the seed is albuminous. Mr. Babington states that at its first formation the ovary is only two-celled, and that the four-celled condition is produced by the midrib of each carpel extending inwardly between the two ovules to the centre of the ovary to which it becomes adherent. Very numerous flat glands have been observed on the young stems by Dr. Lankester and others (*Linn. Proc.* ii. 94). These give a glistening appearance to the plant when growing out of the water, something like that of the *Tetragoniaceae*, which is also owing to the presence of minute glands. [B. C.]

**CALLITRIS.** A genus of Conifers allied to *Thuja*, but differing from it in having the cones with four to six woody scales, which separate one from the other like the valves of a capsule; and three to six winged seeds to each scale. *C. quadrivalvis* is a large tree with straggling jointed furrowed branches, having rings of small scales at the joints. It is a native of Barbary, but is cultivated in this country in sheltered situations. The resin of this tree is used in varnish-making under the name of gum sandarach; while powdered it forms Pounce, used for preparing paper and parchment for writing upon. The timber also, according to Dr. Lindley, is durable, very hard, fragrant, and of a mahogany colour, for which reason it is largely used in the construction of

mosques and similar buildings in the N. of Africa. [M. T. M.]

**CALLIXENE.** A genus of *Liliaceae*, containing branched under-shrubs from extra-tropical South America, with the base knotted, scaly, and leafless, the upper part with alternate half-clasping elliptical leathery leaves with thickened margins, and terminal or axillary flowers on short peduncles. The perianth is six-parted, coloured red, the three inner segments with two glands at the base; stamens six; style thick; berry small, three-celled, with two or three seeds in each cell. [J. T. S.]

**CALLOGRAMMA.** A name given by Professor Fée to *Syngramma allamafolia*.

**CALLOSO-SERRATE.** When serratures are callosities.

**CALLUNA.** The true 'Heather' of Scotland, called also Ling and Common Heath. A low much-branched tufted shrub, distinguished from *Erica* by having a calyx of four coloured leaves concealing a bell-shaped corolla, and accompanied by four bracts resembling an outer calyx, the true heaths having a calyx of four green leaves. *Calluna* derives its name from the Greek *calluno*, to 'cleanse or adorn,' an appropriate name, whether taken in reference to the use to which heather-brooms are applied, or to the exquisite beauty of its flowers. By this plant much of the moorland scenery of Great Britain is redeemed from utter sterility; for being indifferent to soil and capable of enduring a low temperature and the most parching winds, it everywhere finds itself a home, and when it has attained a moderate size hospitably affords shelter to other plants somewhat less hardy than itself. To red and black grouse it affords not only shelter but food, since both these birds are in the habit of concealing themselves among its branches and of feeding on its tender shoots; and it is no less serviceable to the mountain hare (*Lepus variabilis*). The moorland sportsman is therefore indebted to this plant for no small portion of his amusement. It is also much employed as fuel, for thatching houses, weaving into fences, covering underground drains; and a thick layer forms a by no means despicable bed. The flowers abound in honey, and are much frequented by bees. In various parts of Scotland and the north of England, bee-hives are carried, in the beginning of August, from the cultivated to the heathy districts, for the sake of the flowers, where they are allowed to remain two or three months, and are brought back in the autumn. Heather is a plant of slow growth, but very durable on this account; and because it is patient of any amount of clipping it is not unfrequently used as an edging in gardens instead of box. In the common form of the plant the flowers are purplish red, but varieties are cultivated in which this colour is replaced by crimson or white. Another variety with double flowers is well worthy of cultivation. The tint of the foliage

varies considerably, being pale green, purplish, or hoary with down. In all the varieties the flowers retain their form and position long after they have ceased to perform their functions. Ling is found throughout Europe, in the Azores, Greenland, Newfoundland, and rarely in the N. United States. It is the badge of the clan M'Donnell. French, *Brousse commune*; German, *Heide*. [C. A. J.]

**CALLUS** (adj. **CALLOSE**). A hardened part; anything which has acquired unusual hardness and toughness; also used in the sense of verruca; also the hymenium of certain fungi.

**CALOCHEPALUS.** An Australian genus of *Compositae*, consisting of nine species of annual or perennial herbs, or rarely under-shrubs or small shrubs, more or less cottony or woolly, white or rarely glabrous. They have alternate, or in two species opposite, entire mostly linear leaves, and terminal clusters of sessile or pedunculate flower-heads, usually yellow, but white in *C. lacteus*. The achenes are usually compressed, and surmounted by a pappus of several narrow linear scales or bristles, which are sometimes united into a ring at the base. [J. Br.]

**CALOECHILUS** *compactus* is a slender leafy-stemmed Australian Orchid with testiculate roots and nearly closed greenish flowers, the tip of which is deeply clothed with long delicate hairs. *C. karbuccus*, supposed to be a second species, is regarded by Hooker as a mere form of the other.

**CALOCHORTUS.** A genus of beautiful bulbous plants belonging to the *Liliaceae*, and closely allied to *Cyclobothra*, from which it differs in being destitute of a honey-pit on the segments of the perianth, and in having flat smooth instead of roundish angular seeds. They have tunicated bulbs, and produce rigid ensiform leaves, and an erect scape supporting a few large showy flowers which are racemously arranged and remain open for several

days. The perianth is deciduous, six-leaved, the three outer or calycine divisions linear and beardless, the three inner petaloid, very much larger and broader

than the outer, and bearded on the inside; the flowers, therefore, appear to consist of three large spreading petals, and three narrow sepals. There are six stamens adherent to the base of the perianth, and a three-celled ovary crowned by three subsessile stigmas. The few known species, which are found in Mexico, California, and N.W. America, are all plants of gorgeous beauty, but found to be exceedingly difficult of cultivation. *C. reusnatus* is one of the handsomest; it grows about two feet high, and produces large flowers, upwards of three inches across, with narrow green sepals, and broad roundish wedge-shaped petals which form a cup, and are white above, yellowish towards the base, each of them marked with a wedge-shaped deep crimson stain, terminating in a yellow spot, and above this, in the same line, with a deep red spot bordered with yellow, and a spot of lighter red. *C. macrocarpus* is another very fine species, growing nearly two feet high; this has three narrowish sepals very much longer than the petals, which are broad cuneately-obovate, forming a cup, and of a rich rose-purple, paler towards the base, and beautifully bearded with yellow hairs. [T. M.]

**CALODENDRON.** A genus of *Rutaceæ*, so named from the beauty of the flowers and foliage. The flowers are regular, consisting of a five-parted calyx, five narrow spreading petals, hairy on the outside, five fertile stamens, alternating with and shorter than five petal-like sterile ones, which are tipped with a gland and placed on the outside of a shallow tubular disc; style long; fruit a stalked capsule with five angles, and five two-seeded cavities opening by as many valves. *C. capense* is a very ornamental tree, native of the Cape of Good Hope. [M. T. M.]

**CALODRACON.** A genus of *Liliaceæ* plants, which includes several species formerly referred to *Dracæna* and *Cordylina*. The species are natives of the Malayan and Australasian Islands and of China and Japan, and are handsome shrubs with slender cylindrical stems, crowded with leaves at top, the leaves lanceolate oblong, smooth, often beautifully coloured, and having channelled stalks. The flowers grow in large terminal panicles, and are white or rosey violet. The perianth is deciduous, tubulose-campanulate, six-cleft, with the segments somewhat unequal and imbricating; stamens six, with subulate filaments; style subulate with a trifid stigma. This genus, of which *Dracæna ferrea* is the type, agrees with *Cordylina* in having a tubular-campanulate perianth, and with *Dracænopis* in having numerous ovules in each cell of the ovary. *C. Jacquini*, the *D. ferrea* above referred to, is well known under the latter name, and that of *D. terminalis*, in the hothouses of this country, where it is prized for its highly-coloured red leaves, which render it gay at all seasons. *C. nobilis* is another species with the leaves richly variegated

with red; and in *C. Sieboldii* they are deep green with paler blotches. The flowers being small, it is for their foliage and erect palm-like habit alone, that these plants are prized by cultivators. The same name has been given to a section of the genus *Dracocephalum*. [T. M.]

**CALODRYUM.** A genus of *Melincæ* inhabiting the islands of Madagascar, Mauritius, and Bourbon. The calyx is five-cleft; the petals five, more or less adherent; anthers projecting from the tube formed by the united filaments of the stamens; style thread-shaped; ovary five-celled with pendulous ovules. [M. T. M.]

**CALOGYNE.** A name expressive of the peculiarity and beauty of the stigma in the genus of *Goodeniaceæ*, to which it is applied. The genus consists of herbaceous plants with irregular flowers, and a style with three branches, each branch terminated by a kind of cup. The fruit is a two-celled capsule with several seeds. The plants are natives of the coast of tropical Australia, and one has lately been discovered in the neighbourhood of Amoy, in China. The flowers of this latter species are said by Benthams to have an odour like that of hay. [M. T. M.]

**CALONYCTION.** A genus of *Convolvulaceæ*, containing fifteen species, natives of the intertropical regions of Asia and America. They are twining herbaceous plants with alternate cordate leaves and very large showy flowers on axillary ones to three-flowered peduncles. The calyx consists of five sepals; the corolla is funnel-shaped with a long tube, and large spreading limb. There are five exserted stamens, with filaments dilated at the base. The ovary is two-celled with two ovules in each cell; sometimes the rudiment of a secondary dissepiment makes it incompletely four-celled. The four-valved capsule contains four seeds. [W. C.]

**CALOOSE.** The Sumatran name for *Erica tenacissima* and *Bohmertia nitra*, or their fibre.

**CALOPAPPUS.** The name applied to a Chilian genus of plants found on the Cordillera, and belonging to that section of the Composite family with two-lipped corollas. They are low bush-like bushes with needle-shaped leaves set thickly on the stems, and single terminal flower-heads which are stalked or sessile, containing five florets, each having a pappus of about fifteen long needle-pointed awns. Two species are known. [A. A. B.]

**CALOPHACA.** A deciduous shrub allied to *Cytisus*, from which it may be distinguished by its not having all the stamens united into a tube, and by its pinnate leaves. It is a native of desert places near the rivers Don and Volga (hence its specific name *volgarica*). Being hardy and very pretty it is a desirable plant to have in gardens and shrubberies; but is less known than it ought to be in consequence of its being difficult of pro-

pagation except by grafting or from seed. The flowers are yellow, in clusters in the axils of the leaves, and are succeeded by reddish pods. [C. A. J.]

**CALOPHANES.** A genus of *Acanthaceae*, containing nearly thirty species of herbs or under-shrubs, natives of America. They are mint-like plants, more or less pubescent, and nearly related in structure to *Dipteracanthus*. They have axillary opposite generally cymose flowers, with a blue corolla and spotted throat; the calyx is deeply five-cleft with setaceous divisions; the corolla is infundibuliform with a five-cleft limb; the filaments are united in pairs at the base, and have anthers with two parallel cells spurred at the base or rarely muticous. The capsule is lanceolate, with four seeds in the middle. [W. C.]

**CALOPHYLLUM.** This genus of *Guttiferae* (*Clusiaceae*) contains about twenty-five species, the majority of which are natives of the Eastern hemisphere, only four or five being found in America. They are large trees with shining leaves marked by numerous parallel transverse veins, and having racemes of flowers, some of which are of only one sex. Their calyx consists of two or four sepals; their corolla of four petals; the stamens are indefinite in number, their anthers bursting on the inner side; and the ovary is one-celled, the style being crowned with a shield-like lobed stigma. The fruit contains one seed. *C. Calaba*, a native of the West Indies and Brazil, is a tree about sixty feet high, having long elliptical oblong leaves, sometimes notched at the top. It has short racemes of white sweet-scented flowers, producing round green fruits about an inch in diameter, and containing a single seed. This tree is called Calaba in the West Indies, and an oil, fit for burning in lamps, is expressed from its seeds. *C. inophyllum*, an East Indian and Malayan tree, with a trunk about ten or twelve feet in diameter, and from eighty to 100 feet high, has the leaves elliptical and usually notched at the top, and it has white flowers resembling those of the last. The seeds of this tree yield a thick dark green strong-scented oil, employed in India for burning and also medicinally. Its timber is used for building purposes, and for masts and spars; and a greenish coloured resin which exudes from the trunk forms one of the kinds of East Indian Tacamahac. Other species likewise yield resin, such as *C. Tacamahaca* in Bourbon and Madagascar; and *C. brasiliense* in Brazil. The fruits of *C. edule* and *C. Madagasco* are eaten in South America; as also are those of *C. spinosum* in Malabar. In Ceylon the timber of *C. tomentosum* is valued for building purposes, and an oil is expressed from its seeds. [A. S.]

**CALOPHYSA.** A genus of *Melastomaceae* containing a Brazilian shrub with opposite petiolate cordate acute seven-nerved toothed leaves, and short axillary crowded

cymes of flowers; calyx-tube adhering to base of ovary; limb with four short lobes; petals four, obovate; stamens eight, without any appendage to the anthers; berry four-celled, with many seeds; whole plant more or less hispid. [J. T. B.]

**CALOPOGON.** A small genus of tuberous Orchids, inhabiting wet prairies or the edge of pine woods in all parts of the United States. They have grassy radical leaves and naked scapes bearing a small number of purple flowers at the summit. Four species are described: *C. pulchellus*, *multiflorus*, *parviflorus*, and *pellidus*. The generic name has been given in allusion to a handsome beard or tuft of hairs growing from the lip.

**CALOPSIS.** A genus of *Rubiaceae* from the Cape of Good Hope. Sedge-like herbs with deciduous glumiferous flowers in spikelets, arranged in spikes or panicles; stems branched, with spilt leafless sheaths. It is distinguished from *Rostia* by having three stigmas and an indurated not covered with a tough membrane. [J. T. B.]

**CALOSACME.** *Chirita*. [W. C.]

**CALOSANTHUS.** A genus of *Digoniaceae*, consisting of a single species, a native of India. It is a very tall slender smooth tree with large opposite bipinnate leaves, the leaflets shortly petiolate subcordate ovate and acuminate. The racemes are terminal and erect; the flowers large, whitish within, exteriorly streaked with red, and having a fetid smell. The calyx is coriaceous, tubular and truncate; the corolla tube is short and campanulate; its limb sub-bilabiate, the upper lip with two, and the under with three lobes. The five fertile scarcely exerted stamens have the anthers pendulous from the apices of the filaments. The stigma consists of two roundish lobes. The pod-shaped capsule is very long, compressed and two-valved, containing numerous seeds which are surrounded with a large membranaceous wing. The wood is soft, spongy, and of no economic value. [W. C.]

**CALOSCORDUM.** A genus of small-growing Lilyworts, found in China. They are allied to *Allium*, from which they are distinguished by a few technical characteristics. *C. nerioiflorum* has small bulbs and linear leaves which are thick and rounded behind, and the flowers, which are small starry and rose-coloured, form an umbel at the top of a scape. One or two other species are known. The plants have none of the onion-like odour which pervades the *Allium* family. [T. M.]

**CALOSERIS.** The name given to a plant of the Composite family which is found in Venezuela. It has much the habit and appearance of some of the coltsfoots, but belongs to a different section of the family, namely, that with two-lipped corollas. It has been described twice, under different names, and *Caloseris* being the last published, must give place to the first, *Isotrypa*. [A. A. B.]

**CALOSTREMA.** A genus of *Amoryllidaceae* consisting of bulbous herbs with linear-lanceolate leaves, and bearing at the top of the scape a many-flowered umbel of pedunculated flowers. These flowers consist of a cylindrical tube, a funnel-shaped limb, and a coronet or crown, uniting the stamens into a cup, which is sometimes split. The filaments are short and erect; the stigma small and simple; and the ovary usually two-seeded. There are four or five recorded species, all natives of New Holland. *C. purpureum*, with purple flowers, has twelve triangular teeth placed between the filaments on the edge of the staminal cup. *C. luteum* has narrower leaves, and yellow green-ribbed flowers, with six purple spots at the base of the cup, which is toothed as in the former. *C. album* has white flowers and linear teeth to the cup; and *C. carneum* has pretty pale rose flowers, and is without the teeth to the staminal cup, the spaces between the filaments being either emarginate or merely rounded. *C. candidum* is said to be fragrant, and *C. luteum* to have a strong smell of mint. [T. M.]

**CALOSTIGMA.** A genus of *Asclepiadaceae*, containing three species of climbing shrubs, natives of Brazil. They have opposite elliptical or oblong leaves, and lateral interpetiolar peduncles with many flowers. The calyx is five-parted; the corolla bell-shaped with a five-cleft limb, the divisions being long, linear and spreading. The staminal corona is composed of five fleshy leaves, and adheres to the tube of the corolla, above which it projects. The gynostegium is short; the anthers terminate in a short membrane; and the elongated projecting stigma has a prominent dilated apex. The pollen masses are connected by a kneed and, in the upper portion, by a winged process to a linear corpuscle. [W. C.]

**CALOTHAMNUS.** One of the beautiful genera of *Myrtaceae*, in which Australia abounds. The calyx limb has four to five teeth; the petals are four to five; the stamens are arranged in four to five bundles opposite the petals, some sterile or more or less joined to the neighbouring parcel, the anthers attached by the base; the many-seeded capsule is enclosed within the base of the hardened hemispherical calyx tube. The plants are shrubs with scattered needle-shaped leaves. The name indicates that the branches become covered with the beautiful flowers. [M. T. M.]

**CALOTIS.** A genus of simple or branched small Australian herbs of the *Compositae* family. The leaves are alternate, varying much in form, but most generally oblong and toothed. The flower-heads are terminal and solitary; the strap-shaped ray-florets lilac, and rolled backwards spirally after expansion, the disc-florets tubular and yellow. The seed-crown (pappus) consists of two dilated ear-shaped scales, and a few long needle-shaped awns furnished with relaxed bristles. The genus is near

that of the daisy, but differs in the pappus. It receives its name from the two ear-shaped scales of the pappus. *C. cuneifolia* is a slender herb about a foot high with small flower-heads. The awns of the pappus being furnished with very minute reflexed points get entangled in the wool of the sheep, and it is almost impossible to rid them of it. There are about twenty species known. [A. A. B.]

**CALOTROPIS.** A genus of *Asclepiadaceae*, consisting of three species, which form shrubs or small trees, and are natives of the tropics of Asia and Africa. Their flowers have a somewhat bell-shaped corolla, expanding into five divisions, the tube being composed of five angular swellings. The coronet of the stamens is composed of five narrow leaflets, which are united to the central column, but free and recurved at the base, with their edges rolled inwards. The fruits are produced in pairs resembling the horns of an animal, each being swollen or bulged out on the inside; they contain numerous seeds surmounted by tufts of beautiful silky hairs. *C. gigantea*, the largest of the genus, forms a branching shrub or small tree about fifteen feet high, with a short trunk four or five inches in diameter. Its leaves are about six inches long by two or three broad, and egg-shaped, covered on the under-surface with soft silky down, and they are arranged on the stem in pairs, each pair being at right angles with that above and below; its flowers are of a pretty rose-purple colour, and have the segments of the corolla bent downwards. This plant is called Mudar or Ak in Northern, and Yercum in Southern India. The inner bark of its young branches yields a valuable fibre, capable of bearing a greater strain than Russian hemp. All parts abound in a very acrid milky juice, which hardens into a substance resembling gutta percha; but in a fresh state it is a valuable remedy in cutaneous diseases. The bark of the root also possesses similar medical qualities; and its tincture yields *mudarine*, a substance possessing the property of gelatinizing upon the application of heat, and returning to its fluid state when cool. Attempts have been made to spin the silky down of the seeds, but its fibre is too short; a soft kind of cloth is, however, made by mixing it with cotton; paper has also been made from it. Another species, *C. procera*, a native of India, Arabia, Persia, and various parts of Africa, possesses similar qualities. It is a much smaller plant, and has white flowers with straight segments. [A. B.]

**CALPANDRIA.** *Camellia*. [B. B.]

**CALTEA.** A genus of herbaceous plants belonging to the *Ranunculaceae*, distinguished from *Ranunculus* by the absence of a green calyx, and from *Helleborus* by the absence of tubular petals (nectaries). *C. palustris*, the Marsh Marigold, is a stout herbaceous plant with hollow stems, large glossy roundish

notched leaves, heart-shaped at the base, and conspicuous bright yellow flowers, each of which is composed of five roundish petals or sepals. It flowers freely from May to August, and is a native almost throughout the whole of Europe, as well as of Western Asia and North America, in marshy meadows and about the margins of ponds, rivers, and brooks. One of its rustic names is May-Blobs. The flowers, if gathered before they expand, are said to be a good substitute for capers. The juice of the petals boiled with alum stains paper yellow. A double-flowered variety is commonly cultivated in gardens, and the wild plant is liable to several variations, dependent on soil and situation. Several foreign species are enumerated by botanists, all of which are natives of marshes or shallow water, and more or less approach *C. palustris* in habit. The *Caltha* of the Latin poets is considered to be the common garden marigold. French, *Populeux*; German, *Bumpf-dotter-blume*. [C. A. J.]

**CALTROPS.** The common name for *Tribulus*. —, **WATER.** That of *Trapa*.

**CALUMBA, CALOMBA, or COLOMBO.** The root of *Cocculus palmatus*, now called *Jateorhiza palmata*. —, **FALSE or AMERICAN.** The root of *Fraxera Waltieri*.

**CALVOUS.** Quite naked: bald; having no hairs, or other such processes.

**CALYBIO, CALYBIUM.** A hard one-celled inferior dry fruit, seated in a cupule; as an acorn, or a hazel-nut.

**CALYCANTHACEÆ (Calycanthæ).** The Carolina Allspice family, a natural order of Calycifloral Dicotyledons belonging to Lindley's Rosal alliance. Shrubs with square stems having four woody axes surrounding the central one, opposite entire leaves without stipules, and solitary lurid flowers. Calyx of numerous coloured sepals compounded with the petals, and all united below with a fleshy tube bearing numerous stamens on its rim; outer stamens opening outwardly, inner ones barren. Ovaries several, one-celled, adherent to the calycine tube; ovules one to two. Fruit consisting of achenes inclosed by the calyx; seeds without albumen. Natives of North America and Japan. Their flowers have an aromatic fragrance, and their bark is sometimes used as a carminative against flatulence. The bark of *Calycanthus floridus*, Carolina Allspice, is used as a substitute for cinnamon. There are two known genera, viz., *Calycanthus* of America, and *Chimonanthus* of Japan, comprising six species. [J. H. B.]

**CALYCANTHUS.** A genus giving its name to the family *Calycanthaceæ*, and composed of N. American shrubs with opposite oval or ovate-lanceolate entire leaves, generally rough on the surface; axillary or terminal solitary stalked flowers made up of a great number of lurid purple-coloured narrow sepals and petals; and very numerous stamens, inserted on the

mouth of the calyx-tube, which bears on its inner hollow surface numerous achenes, each with one or two seeds. *C. floridus* is a native of many parts of the United States, where it is called Carolina Allspice, or Sweet-scented shrub. Its wood and roots have a camphorlike smell, and the aromatic bark is said to render it useful as a substitute for cinnamon in the United States. The flowers and leaves have a scent resembling that of the quince. This species and the following are often to be met with in English gardens. Some of its varieties are scentless, and it varies much in the form and pubescence of the leaves as well as in the colour of the flowers. These varieties have by some authors been considered as species. *C. occidentalis*, the only other species, is a native of California. It differs chiefly from the Carolina Allspice in its long flower-stalks, and the cordate base of the leaves. Its flowers are more than three inches across when fully expanded. [A. A. B.]

**CALYCERACEÆ (Boopideæ).** The Calycera family, a natural order of gamopetalous Calycifloral Dicotyledons included in Lindley's Campanal alliance. Herbs with alternate leaves without stipules, and with flowers collected in heads. Calyx superior, of five unequal divisions; corolla regular, funnel-shaped, with a five-divided limb; stamens five, their filaments united, as well as the lower part of the anthers. Ovary one-celled; style smooth; stigma capitate. Fruit an achene, usually crowned by the rigid spiny segments of the calyx. The order occupies an intermediate place between *Compositæ* and *Dipsacaceæ*, differing from the former in their seed, which is pendulous and albuminous as in *Dipsacaceæ*, and from the latter in their anthers being united around the style as in *compositæ*. There are about twenty species, distributed into six or eight genera. They are natives of South America, found chiefly on the Andes of Chili; two species extend to the Cordillera of Peru; three are found near the straits of Magalhães; seven in the eastern part of S. America, near the Rio Plata; and one from Rio Janeiro, as far as Bahia. The plants do not possess any marked qualities. Illustrative genera: *Boopis*, *Calycera*, *Acicarpa*. [J. H. B.]

**CALYCERA.** This genus gives the name to the family to which it belongs. It is confined to South America, and the species are mostly found on the Cordillera of Chili. They are small annual or perennial herbs, four to eight inches high; the leaves alternate oblong toothed or pinnatifid, and generally smooth; the flower-heads single terminal and shortly stalked. The genus differs from the others in the family by the presence of two sorts of flowers in the same head, the one set with the calycine teeth flattened and produced into spinous points after flowering, the other not so. The achenes are free and seated on a broad depressed receptacle. The few species are only interesting to the botanist. [A. A. B.]

**CALYCFLOREÆ.** A sub-class of Exogenous or Dicotyledonous plants characterised by having both calyx and corolla, petals usually separate, and stamens attached to the calyx. [J. H. B.]

**CALYCINAL.** Of or belonging to the calyx.

**CALYCINE.** Of or belonging to a calyx; also a calyx of unusual size; or having the texture of a calyx.

**CALYCOIDEOUS.** Resembling a calyx.

**CALYCOMIS.** A genus of *Cunoniaceæ*, described by Don, and eight years afterwards renamed by Benthams, *Acrophyllum*. The latter name has been generally adopted, but contrary to the received laws of botanical nomenclature. [J. T. S.]

**CALYCOPHYLLUM.** A genus of *Cinchonaceæ*, remarkable for one of the five segments of the calyx being much larger than the rest and petal-like, a peculiarity observable also in an allied genus, *Mussonia*. The corolla is bell-shaped, the stamens inserted into its throat; the stigmas are two, reflexed; the fruit is an oblong capsule, opening at the top to allow of the escape of the numerous slightly-winged seeds. The plants are natives of the West Indies and Brazil. [M. T. M.]

**CALYCOSERIS.** The generic name of a little annual herb of the Composite family, found by Mr. Wright in New Mexico, and named after its discoverer *C. Wrightii*. The plant has pinnatifid leaves with linear segments, and yellow flower-heads; and altogether it bears much resemblance to *Crepis virens*, a plant which is very often met with in dry pasture lands throughout Britain. The achenes being furnished with a double pappus, the outer small and cup-shaped, the inner of long soft white hairs, and the receptacle being furnished with numerous capillary bristles, are the most marked characters of the genus. [A. A. B.]

**CALYCOTOME.** A genus of the Leguminous family, distinguished from that of the broom by the teeth of the calyx falling away early and leaving a notched membranous tube. The species are all thorny shrubs. *C. spinosa* is a stiff spiny bush with trifoliate leaves and numerous yellow flowers, in size like those of the laburnum, but single in the axils of the leaves. It is a native of Southern Europe and North Africa, as are all the species, and is well adapted for growing in shrubberies. It is in cultivation in England. The pods of *C. lanigera* are covered with long rusty hairs. All the parts of *C. intermedia*, an Algerian species, are covered with white silvery hairs. [A. A. B.]

**CALYCYLUS.** A partial involucre, containing but one, or perhaps two flowers. Also the external bracts of a capitulum, when they form a distinct ring or ring.

**CALYDORÆA.** The name of an Iridaceous genus separated from *Sisyrinchium*,

and of which *S. speciosum* is taken as the type. This plant, now called *Calydorea speciosa*, is a beautiful bulbous herb with a few narrow linear leaves, and a slender subramose scape, five to six inches high, bearing deep blue purple flowers with a yellow centre, the segments of which are spreading, the three inner ones smaller than the outer. It is distinguished from *Sisyrinchium* by its unequal instead of regular perianth, the petaline divisions of which are reflexed and much smaller than the sepaline, its subulate free filaments, and its trifid spreading style, with emarginate-spathulate fimbriated stigmas. The species is a native of Chili. [T. M.]

**CALYMELLA.** *Gleichenia*.

**CALYMENIA, CALYXYMENIA.** These names occasionally met with in gardens, refer to some inconspicuous plants now referred to *Oxybaphus*. [M. T. M.]

**CALYMMODON.** A small genus of polypodiaceous Ferns belonging to the *Gymnogrammeæ*. There are three or four species, found in Java and other eastern islands, and consisting of small plants with fasciculate thin pinnatifid fronds, growing from a short, erect stem, the fertile lobes folded longitudinally so as to partially cover the sori, which, though elongated, have a tendency to the polypodioid structure. The veins are simple and the sori oblong, seated at the tip of the simple vein which occupies each lobe. [T. M.]

**CALYPSO borealis** is the most beautiful of northern Orchids, being found all over the continents of Europe, America, and Asia in high latitudes, growing in woods, especially of firs, and appearing as soon as snow has melted. It is a tubercous terrestrial plant, with one leaf and one flower only. The leaf is thin, many-nerved, and either ovate or cordate. The rose-coloured flower appears at the end of a slender sheathed stem, and has something the appearance of a *Cypripedium*, owing to its forming a large pouch. The genus appears to be nearly related to *Calogyne* and especially to the section *Pleione*.

**CALYPTRA** (adj. CALYPTRATE). The hood of an urn-moss.

**CALYPTRANTHES.** This name of Lid-flower has been applied to a genus of *Myrtaceæ*, in allusion to a lid which the upper part of the calyx forms, and which falls off as the flower expands. These flowers have five very small petals, which are sometimes absent; stamens numerous, distinct; berry one-celled, one to four-seeded. They are American and West Indian shrubs, some of which are in cultivation. The flower-buds of *C. aromatica* might, according to Lindley, be used in the place of cloves. [M. T. M.]

**CALYPTRIDUM.** A genus of the Purslane order, chiefly distinguished from its allies by having the corolla composed of three pieces joined together so as to form a conical tube, three-toothed at the

top, and covering the seed-vessel like a hood; the name indicates this, being derived from two Greek words signifying 'hood-like.' The only known species is a low succulent plant, a native of California, with alternate leaves and small flowers of a pale rose colour. [G. D.]

**CALYPTRIFORMIS.** Like an extinguisher, as the calyx of *Eucalyptus*.

**CALYPTROSTIGMA.** This name is sometimes given to a plant of the Honey-suckle family, a N. Asian shrub with opposite leaves, between ovate and lanceolate in form, and having serrated margins. The flowers are yellow, six to eight in a cluster at the ends of the branches, and in size and form much like those of the fox-glove. The stigma is more or less lobed, and sits like a cap on the top of the style, whence the generic name. By many the genus is not considered different from the well-known *Weigela* or *Diervilla*; and the plant is now in cultivation under the name of *Diervilla Middendorffiana*. [A. A. B.]

**CALYBACCION.** *C. longifolium* is the only species of this genus of thutifers (*Clusiaceae*). It is a handsome large tree, found in abundance in South Western India, and also in China. Its leaves are opposite, and of a long narrow lance-like form, and thick leathery texture. Some of its flowers are perfect, while others are of distinct sexes, and sometimes borne on different trees. Their calyx, which is globular in the bud, bursts into two pieces; and their corolla consists of four, or rarely five, small concave petals of a yellowish tint streaked with red; the stamens are numerous, arranged in several rows, and either quite free or slightly connected at the base; while the two-celled fleshy ovary is terminated by a short style, and a broad very-fleshy flat-topped stigma. The fruit is unknown. This tree has several local Indian names, such as Surinee and Soorree, and is interesting on account of the uses made of its flower-buds. These are known by the name of Nag-Kassar or Nagassar; but the same name is applied to the buds of a nearly allied plant, *Morus ferrea*, with which they have been confounded. They are on long stalks and about the size of peppercorns, of an orange-brown or cinnamon colour, and very fragrant, possessing an odour like that of violets or orris-root. In India they are greatly esteemed on account of their fragrance, and are commonly sold in the bazaar; they are also used for dyeing silk, yielding a yellow, or, with sub-carbonate of potash, a deep-orange colour. A quantity of them was imported into London some years ago, but they did not receive the attention they deserved. [A. S.]

**CALYSTEGIA.** A genus of *Convolvulaceae*, containing about twelve or fourteen species, widely diffused in extratropical regions all over the world. They are climbing or prostrate smooth herbs with milky juice. The leaves are alternate

without stipules, and the large and beautiful flowers are solitary, axillary and peduncled. The calyx of five sepals is enclosed in two leafy bracts. The corolla is bell-shaped, plaited and five-lobed. The ovary is semi-bilocular with four ovules, and bears a simple style and a stigma consisting of two obtuse lobes. The capsule has only a single cell. This is a very distinct genus, easily separated from *Convolvulus* and the allied genera, by the leafy bracts at the base of the calyx, and by the one-celled capsule. It includes the Common Bindweed, *C. septem*. [W. C.]

**CALYTHRIX** or **CALYOTHRIX.** A genus of *Chamaelaniaceae* from Australia. Small shrubs with short cylindrical sheath-like leaves, often on short footstalks, and small stipules; flowers axillary, nearly sessile, frequently clustered near the extremities of the branches; calyx with a long tube, adhering to the ovary at the base, and a five-lobed limb, each lobe terminating in a bristle from which the genus takes its name; petals five, purplish, yellow or white; stamens ten or more; ovary inferior, one-celled, two-ovuled; capsule with five ribs, indehiscent. [J. T. S.]

**CALYX.** The most external of the floral envelopes; it is called adherent or superior when it is not separable from the ovary, free or inferior when it is separate from that part, and calyculate when it is surrounded at the base by bracts in a ring. Also the receptacle of some kinds of fungals. — **COMMUNIS.** The old name of the involucre of composites, &c.

**CAMARA.** A carpel. Also the name of a hard durable timber obtained in Guiana from *Dipteryx odorata*.

**CAMARIDIVM.** Under this name have been collected many species of Orchids from tropical America, with the structure nearly of *Cymbidium*, but with distichous leaves and often proliferous stems. Some of them have been referred to *Taechinus*, a wholly different genus. About a dozen species are known, of little interest. The genus differs but little from *Ornithidium*.

**CAMAROTIS.** A small genus of scandent Orchids, with narrow hard leaves and lateral racemes of delicate yellowish, rose or purple flowers. They are remarkable for having a long slender rostell, and a fleshy lip hollowed out into the form of a slipper. By means of very long hard roots they cling to the bark of trees in India, the Philippines, and New Guinea. *Micropera* is the same genus, with lemon-coloured blossoms.

**CAMASSIA.** The Quamash of the North American Indians is the only plant belonging to this genus of Lilyworts (*Liliaceae*). It is the *Camassia esculenta* of botanists, a small bulbous plant resembling the common blue hyacinth, but larger, its leaves being about a foot long, very narrow and grooved down the inside; and its flower

stalks growing a foot or a foot and a half high, and bearing from twelve to twenty blue or white flowers. The principal character of the flower consists in its having a calyx of six sepals slightly connected at the base, and spread out horizontally but not equally, the five upper ones being closer together and inclined upwards, whilst the lower or sixth stands by itself and is bent downwards, each petal having three prominent nerves on its outside, and a stamen attached to its base on the inside, and they do not fall off, but wither and remain till the fruit is ripe. The ovary is nearly round, and is divided into three cells, each of which contains numerous ovules attached to the centre in two rows. This plant grows in great abundance in swampy plains on the north-west coast of America and Vancouver's Island, and its bulbs form the greater part of the vegetable food of the Indians, the different tribes visiting the plains for the purpose of collecting them, immediately after the plant has flowered. The digging of Quamash is a time of feasting and rejoicing amongst the Indians; the entire labour, however, devolves upon the

*Camassia esculenta.*

women; and the unmarried females endeavour to excel each other in the quantity of the roots they collect, their fame as future good wives depending upon their activity in the Quamash plains. The roots are cooked by digging a hole in the ground and paving it with large stones, upon which a fire is lighted and kept up until they are red-hot, when they are covered with alternate layers of branches and roots till the hole is full: it is then covered with earth and a fire kept burning upon it for twenty-four hours, when the roots are taken out and dried, or pounded into cakes for future use.

[A.S.]

**CAMBESSEDESLA.** A genus of Melastomaceae, consisting of erect or ascending dichotomously-branched Brazilian shrubs, with the leaves at the apex of the branches, sessile, opposite, or verticillate, ovate, oblong, or linear, generally three-nerved;

flowers handsome, terminal and axillary in paniculate cymes; calyx bell-shaped, with a five-lobed limb; petals five, obovate, scarlet; stamens ten; ovary free, three-celled; capsule ovate-globose. [J. T. S.]

**CAMBIUM.** The viscid fluid which appears between the bark and wood of Exogens, when the new wood is forming. Also the mucus of vegetation out of which all new organs are produced.

**CAMBOGIA.** A genus of tropical shrubs belonging to the *Cistaceae*, and containing one of the plants which yields the well-known pigment gamboge. They have leathery simple leaves; the male and female flowers, on different trees, and the petals white with a pink tinge towards the base. The name *Cambogia* is given from the circumstance of the drug being produced in greatest quantity in that part of Siam called Cambodja. Linnæus strangely confounded two Ceylon plants under the name *Cambogia Gueta*, (the one, *Garcinia Cambogia* of Desrousseaux, yielding an insoluble gum-resin, and varying with red and yellow fruits; the other, *G. Morella* of Desrousseaux, and the *Ebradendron cambogioides* of Graham. This latter species is, according to Mr. Thwaites, the only one growing in Ceylon from which gamboge is obtainable.)

Two kinds of Gamboge are known, the Ceylon gamboge and the Siam gamboge, both of them gummy-resinous exudations, obtained from the wounded stems of the trees or by breaking of the leaves and young twigs, and receiving the yellow juice as it drops in suitable vessels. That of Ceylon is sold in the bazars on the Coromandel coast, and is said to be as good as the Siamese, but the process it goes through in preparation does not purify it sufficiently, and, therefore, it is not sold so readily as that from Siam. By far the greater portion of the gamboge so extensively used in the arts, as a water-colour, and as a varnish for lacquer work, as well as in medicine, is sent from Siam, and is supposed to be the produce of a *Garcinia*, [which has been considered to be a variety of *G. Morella*]. It is said to form part of the tribute paid to the kings of Siam, and is sent to England from Singapore in boxes or bags, or from one to two hundred weight each, the amount annually imported being about 800 cwt. Gamboge is known in commerce in three distinct forms: in rolls or solid cylinders, in pipes or hollow cylinders, and in cakes. The two former are collected in the same manner, the juice when in a liquid state being run into hollow bamboos, about twenty inches long and one and a half in diameter, and allowed to harden. In this form it is known as pipe gamboge. The cake or lump gamboge

powerful purgative in doses of three, five, or seldom more than seven grains; on the other hand, it is a dangerous poison in large doses, causing death

by violent inflammation of the bowels. Dr. Christison thinks that the fatal effects which sometimes follow the use of Morrison's Pills arise from the large amount of gamboge in their composition. A detailed account of the gamboge is given by Drs. Christison and Graham, in *Hooker's Companion to the Botanical Magazine* (II. 193, *Plumbago* and *Hebradendron* are now generally referred to the genus *GARCINIA*: which see. [A. A. B.]

**CAMBON.** An Indian name for the grain of *Pennisetum typhoides*, the *Holcus spicatus* of Linnaeus.

**CAMBUY.** The fruit of a species of *Eugenia*.

**CAMEL'S HAY.** *Andropogon Schamantina*.

**CAMEL'S THORN.** *Alhagi Camelorum*.

**CAMELE'E.** (Fr.) *Daphne Oncorum*.

**CAMELINA.** A small genus of cruciferous plants (*Brassicaceae*), containing two or three European and North American species. They are dwarf annual or perennial herbaceous plants, with stem-clasping leaves, and terminal racemes of yellow flowers. The fruit or pod is somewhat egg-shaped, with the broad end upwards, and has a broad partition parting it in two, each half being very convex, distinctly marked by a central rib or nerve, and having its edges flattened so as to form a narrow border round the pod. The seeds are numerous, and have their radicle, or rudimentary root, folded over upon the back of one of the cotyledons, or rudimentary leaves.

The most interesting species is the *Camelina sativa*. This plant is found growing in cultivated and waste places in Central and Southern Europe, and the temperate parts of Russian Asia; it is generally enumerated amongst the indigenous plants of the British Isles, but it is a very questionable native, being found only in corn and flax fields in England and Ireland, having most probably been introduced along with foreign seeds. It is an annual plant, growing about two feet in height and having a somewhat branching stem; its leaves are lance-shaped, and about two inches long, with their margins entire or slightly toothed, the lower ones having stalks, whilst those higher up have their bases shaped like those of arrow-heads and clasp round the stem. The flowers are in long loose racemes, and produce pear-shaped pods, about a quarter of an inch long, containing numerous small seeds. The English name of the plant is Gold of Pleasure, but why it is so called is unknown. It is cultivated in some parts of the Continent, both on account of the fibre of its stems and the oil obtainable from its seeds, and it has been recommended for cultivation in this country, but it is not likely to prove a profitable crop. The seeds are sometimes imported under the name of Dodder seed, but they have no

thing to do with the true dodder, which belongs to a widely different natural order. By pressure they yield a clear yellow-coloured oil, smelling something like common linseed oil; and the residual cake has been recommended as a food for cattle, but it is of too acrid a nature to be applied to such a purpose. The stems contain a considerable proportion of fibre, and are commonly used for making brooms in many parts of Europe. [A. B.]

**CAMELLIA.** A well-known genus belonging to the Tea family (*Ternstroemiaceae*), and so nearly related to the teas (*Thea*) as to be with difficulty distinguished from them. The differences that do exist consist in the number of the parts and in the position of the flower. In *Camellia* the calyx leaves are numerous and fall early, the interior stamens twice the number of the petals, the styles generally five, and the flowers sessile and erect; while in *Thea* the calyx leaves are five in number, the interior stamens equal in number to the petals, and the flowers are stalked and drooping. These are generic distinctions as given by Dr. Seemann, and they involve the removal to the teas of a number of plants which have been known as species of *Camellia*.

Camellias are found in the eastern portion of the Himalaya, Cochin China, a great portion of China Proper, and Japan; two species, moreover, are found, the one in Java, the other in Borneo and Sumatra. The genus is named in honour of George Joseph Kamel, a Jesuit, who travelled in the East, the name being Latinised into *Camellus*. The first species cultivated in European gardens was the Japanese *Camellia*, *C. japonica*. It is said to have been introduced in 1739, by Robert James, Lord Petre; this was the single red-flowered or normal form of the species. It was not until 1793 that any of the double-flowered varieties were brought to this country: then the double white and the striped were introduced, both from China; they were shortly followed by the double red. Many more were subsequently introduced, and with these introductions, and the varieties produced from them, through the exertions of cultivators, we have now an endless variety of forms of this beautiful plant. The most marked among them are the double white, the fringed white, which is the only variety with fringed petals, and the anemone-flowered or Waratah *Camellia*, which has a margin of broad petals and a raised centre of smaller ones, somewhat like the flower of a double hollyhock.

The Net-veined *Camellia*, *C. reticulata*, a native of Hong-Kong, is the largest-flowered of the species. The flowers are sometimes six inches or more in diameter, and not unlike those of a *Paeonia*. The petals are not so closely set as in the other species, but it is highly probable that cultivators will be able to do as much for this species as they have done for the Japanese one, although it is said to be difficult of propagation.

*C. Sasangu* (*Sasangu* is the Japanese

name of the plant) is found in many parts of China and Japan; it has small white scentless flowers, and is cultivated in English gardens. An oil is obtained from the seeds in China by crushing them to a coarse powder, afterwards boiling them, and finally subjecting them to pressure. The oil has an agreeable odour, and is used for many domestic purposes. The leaves are used in decoction by Japanese women to anoint the hair, and also in a dried state to mix with tea, on account of the pleasant odour contained in them. *C. drupifera* is nearly allied to *C. Sasanqua*, but differs in having a very long point to its ovate-lanceolate leaves; like it the flowers are small and white, but odoriferous; it is also in cultivation, and its seeds yield an oil used in medicine in Cochii China. This grows in great abundance on the eastern portions of the Himalaya. The lance-leaved *Camellia* is found in Sumatra and Borneo; and the only other species, *C. quinosaurea*, is said to be a native of Java. The pink-flowered plant known sometimes in gardens as *Camellia Sasanqua*, as well as the plants usually called *C. roseiflora* and *C. multiflora*, is now referred to the genus *Tsai*; which see. The present genus includes *Culpantria*. [A. A. B.]

**CAMERARIA.** A genus of the Dogbane family (*Apocynaceæ*), having a small five-cleft calyx; a funnel-shaped corolla with a long tube inflated at each end, and a flat limb with five lance-shaped oblique segments; the connective of the anthers prolonged into a thread; and the two follicles swollen at the base on each side so as to appear three-lobed. The seeds are compressed and slightly winged at the top. Some of the species being shrubs with white or orange flowers, are cultivated in our stoves. [M. T. M.]

**CAMÉRISIER.** (Fr.) *Lonicera Xylotum*.

**CANMOCK.** The Rust Harrow, *Ononis arvensis*.

**CAMOMILE.** The common name for *Anthemis*; more frequently written Chamomile.

**CAMOMILE DES CHIENS.** (Fr.) *Anthemis* or *Martia Cotula*. — **FAUSSE.** *Anthemis arvensis*. — **ROMAINE.** *Anthemis nobilis*.

**CAMOTE.** A Spanish name for the Sweet Potato, *Dioscorea edulis*.

**CAMPANILLE.** (Fr.) *Wahlenbergia*.

**CAMPANULACEÆ.** (*Campanula*, Bell-wort, Hare-bell family.) A natural order of Calycifloral gamopetalous Dicotyledons, characterizing Lindley's Campanulales. Milky herbs or undershrubs with alternate leaves having no stipules, and usually with showy blue or white flowers. Calyx above the ovary (superior), commonly five-cleft, persistent; corolla regular, bell-shaped, usually five-lobed, withering; stamens five, distinct; style with hairs. Fruit one or two-

celled or many-celled; capsule opening by slits at the sides or by valves at the apex; seeds numerous, albuminous, attached to a central placenta. Chiefly natives of the north of Asia, Europe, and North America, and scarcely known in hot regions. In our hemisphere the greatest number of species are found between 36° and 47° of north latitude. The chains of the Alps, Italy, Greece, Caucasus, and the Altai are their true country. Several are found at the Cape of Good Hope. The species opening with lateral slits in the seed-vessels are chiefly natives of the Northern hemisphere; those opening by valves at the top of their seed-vessels belong to the Southern hemisphere. The plants have a milky acrid juice; but the roots and young shoots are often cultivated as articles of food, as in the case of the Ranuncul *Campanula Rapunculus*. There are twenty-nine known genera and 540 species. Illustrative genera: *Jasione*, *Phyteuma*, *Campanula*, *Platycodon*, and *Adonis*. [J. H. B.]

**CAMPANULA** or Bell-flower. An extensive genus of herbaceous plants giving its name to the order *Campanulaceæ*. No less than 200 species of this family have been described, of which upwards of eighty are said to be either indigenous or cultivated in Great Britain. They are chiefly natives of the north of Asia, Europe, and North America, and are scarcely known in the hot regions of the world. In the meadows, fields, and forests of the countries they inhabit, they constitute the most striking ornament. Many abound in milky juice, which is rather acrid; but, nevertheless, the roots and young shoots of some species are occasionally eaten. *C. Rapunculus* (a diminutive of *raps*, a turnip, whence the English name Ranion) is much cultivated in France and Italy, and sometimes in Britain, for the roots, which are boiled tender, and eaten hot with sauce, or cold with vinegar and pepper; *C. persicifolia* and *C. rapunculoides* may also be cultivated for the same purpose. Of the British species, *C. latifolia* is the finest and most stately; the flowers are very large, blue, or (in the Scottish woods) sometimes white. *C. Trachelium*, the nettle-leaved Bell-flower, formerly considered a specific for sore throat (Greek *trachelos*, a neck), is remarkable for the resemblance borne by its leaves to the common plant after which it is named. *C. glomerata* is a handsome plant with large erect flowers crowded into a kind of head. The more edible species, mentioned above, are sometimes also found apparently wild; but it is doubtful whether they have not escaped from cultivation, having been grown commonly in gardens before the time of Gerard. The best-known species is *C. rotundifolia*, Hare-bell, Hare-bell, or Witches' Thimbles, the Blue-bell of Scotland, an elegant plant about a foot high, with a branched wiry stem and graceful drooping pale blue, sometimes white, flowers. The stem-leaves of this plant are exceedingly narrow, and seem to belie the name *rotun-*

*diffolia*, but the root-leaves, which for the most part wither away early in the season, justify the appellation. It has been said that Linnaeus gave this plant its name from having just seen the round leaves on the steps of the university of Upsal. This, however, may hardly be, as it is figured and described under the same name by Gerard (1597). *C. hederacea* is an exquisite little plant, very abundant by the side of streams in the extreme west of England, generally growing with *Anagallis tenella*. The ivy-shaped leaves are of a remarkably fine texture, and delicate green hue; the flowers of a pale blue, sometimes slightly drooping, and supported on long stalks scarcely thicker than a hair.

Of the cultivated species *C. pyramidalis* was a very fashionable plant thirty years ago, and is still cultivated in Holland as an ornament to halls and staircases, and for being placed before fire-places in the summer season. It is still, too, a great favourite in cottage windows in England. In the shade it will continue in flower for several months. *C. lilifolia* is so called from its having at the summit of its stem a tuft of leaves resembling a double flower, which disperse as the stem elongates. 'All the species are elegant and handsome when in blossom, and are well adapted for decorating flower-borders. Some of the smaller perennial kinds answer well for decorating rockwork, or to be grown in pots, among other Alpine plants.' None are more worthy of being cultivated than the white variety of *C. rotundifolia*. French, *Campanule*, German, *Glockenblume*. [C. A. J.]

#### CAMPANULATE, CAMPANIFORM. Shaped like a bell.

**CAMPANUMOEIA.** A genus of *Campanulaceae* containing herbs from Java and India, with tuberous roots and milky juice. The leaves are opposite stalked ovate-cordate or oblong-linear, glaucous beneath. The flowers are solitary or subcorymbose; the calyx with a hemispherical tube, surrounded by a five-parted involucre, its limb truncate; the corolla five-parted; stamens five; ovary inferior, three-celled, capsule globose, five-angled. [J. T. S.]

**CAMPEACHY or CAMPECHE-WOOD.** The red dye-wood, better known as Logwood, obtained from *Hæmatoxylon campechianum*.

**CAMPELEPIS.** An *Asclepiadaceous* genus belonging to the division *Periploceae*, containing a single species, a native of Lower Bactria. It is an erect branching almost leafless shrub, the remote deciduous leaves being like scales, and the small coriaceous flowers in few-flowered cymes. The calyx is five-parted; the corolla rotate and five-cleft, its throat crowned with five short trilobed scales alternating with the segments; the five stamens have distinct filaments inserted in the throat of the corolla below the scales, and sagittate anthers, with the pollen-masses solitary and granular; the stigma is dilated; the

follicles are slender, cylindrical and spreading, with numerous comose seeds. [W. C.]

**CAMPELIA.** The name of a genus belonging to the order of Spiderworts, having three petals which remain attached after flowering, and form a cover to the fruit; the style or appendage on the top of the seed-vessel being smooth, bent down, and ending in a round head which has three slight subdivisions. The species, natives of America and the warmer parts of Asia, are perennial herbs with erect stems, the leaves broadly lance-shaped and hairy on the lower surface. *C. Zanonis*, a native of the West Indies, &c., cultivated since 1758 under the name of *Tradescantia Zanonis*, is an interesting species. [G. D.]

**CAMPHOR.** A well-known stimulant drug, a kind of stearoptene, obtained from *Camphora officinarum*. —, BORNEO or SUMATRA. The drug produced by *Dryobalanops aromatica*, sometimes called *D. Camphora*.

**CAMPHORA.** The tree which furnishes camphor, *C. officinarum*, was referred by Linnaeus to the genus *Laurus*, but subsequently it has been removed into a new genus of *Lauraceae*, with a more significant appellation. This separated genus differs from *Laurus* in its ribbed leaves, the lesser number of its fertile stamens (nine), and its four-celled anthers. From *Cinnamomum* it differs in having its leaf-buds protected

*Camphora officinarum.*

by scales, and in the calyx being membranous instead of leathery. Camphor is prepared from the wood of the tree by boiling the chopped branches in water, when, after some time, the camphor becomes deposited, and is purified by sublimation.

It is produced principally in the island of Formosa, and is imported from Singapore, &c. Another kind of camphor is imported from the Dutch settlement of Batavia. What is known as Borneo camphor is the produce of a tree of a different family: see DRYOBALANOPS. Camphor has acrid stimulant properties, and in large quantities is poisonous. There is a very prevalent but erroneous notion that camphor acts as a preventative in infectious diseases. It is, however, much used to prevent the ravages of insects in clothes, and in cabinets of natural history. The wood of the tree is occasionally imported to make cabinets for entomologists. [M. T. M.]

**CAMPBOROSMA.** A genus of *Chenopodiaceae* consisting of small shrubs or herbs chiefly natives of the saline steppes of Central Asia, though one species occurs in the Mediterranean region. Leaves small, linear or awl-shaped, often downy, scattered or fasciculate; flowers very small, axillary, crowded; calyx tubular, compressed, four-toothed, two of the teeth larger and keeled; stamens four; style two or three-cleft. Fruit a membranous utricle contained in the unchanged calyx-tube. The seeds are vertical with a membranous seed-coat and an annular embryo with green cotyledons; they contain a pungent volatile matter. [J. T. S.]

**CAMPHEREE.** (Fr.) *Camphorosma monspeliaca*.

**CAMPUSIA.** A genus of *Goodeniaceae*, characterised by a superior calyx; an irregular corolla having a curved tube and a three-cleft limb with narrow segments; anthers distinct; ovary with two cavities, each containing one ovule; style flattened, glabrous, wavy; stigma large, round, its cup ciliated. The genus has been separated from *Scavola*, and consists of one species, *C. glabra*, a tree inhabiting the island of Oahu, and bearing entire tufted leaves and large yellow solitary flowers. [M. T. M.]

**CAMPION.** *Ocubalus baccifer*. —, **BLADDER.** *Silene inflata*. —, **CORN.** *Agrostemma Githago*. —, **MEADOW.** *Lychnis Flos-cuculi*. —, **MOSS.** *Silene acaulis*. —, **OF CONSTANTINOPLE.** *Lychnis chalcodonia*. —, **ROSE.** *Lychnis coronaria* and *L. Flos Jovis*. —, **RED.** *Lychnis diurna*. —, **WHITE.** *Lychnis viscaria*.

**CAMPUM.** A synonym of *Pacilopteria*.

**CAMPSIDIDIUM skilense.** The southernmost representative of the order of *Bignoniaceae*, and the only known species of the genus to which it belongs. It is a very handsome climber, with dark shining pinnate leaves, and flowers having a regular five-cleft calyx, a tubular almost regular corolla, of a rich orange colour; and five stamens, one of which is sterile, the anthers placed parallel (a peculiarity shared with only two other bignoniads, *Bignonia venusta* and *Millingtonia hortensis*). The plant grows in woods,

ascending the trees to the height of forty or fifty feet. It is found in Chili and the adjacent islands, from latitude 40° to 44° south; the Isle of Huasco, where it was found by Egleta, being the southernmost station at present known. According to Mr. Bridges, the inhabitants of Chiloe term it 'pilpil boqui.' [B. S.]

**CAMPSIS.** A genus of *Bignoniaceae*, consisting of half-a-dozen species distributed over the Eastern Archipelago, China, Japan, and North America, and distinguished from all other members of the order by the branches being climbing and rooting like ivy, eminently qualifying these plants for covering walls and rocks, for which purpose two species, *C. adrepens* (*Bignonia*, or *Tecoma grandiflora*, of some writers) and *C. radicans* (*Bignonia*, or *Tecoma radicans* of botanists, the jacintrumpet of the French, or Trumpet-flower as we call it) are already used in our gardens. The calyx is regular, with five acute lobes, valvate in maturation; the corolla funnel-shaped, large; the stamens five in number, one of them being sterile, and the four fertile ones of unequal length. The capsular fruit is of oblong shape, two-celled, and the partition runs contrary to the direction of its valves, whilst the winged seeds are arranged in several rows at each side of the partition. The branches are slender; the leaves impart-pinnate, with the leaflets either entire or serrated; and the flowers arranged in terminal bunches, and either pink or of a rich orange colour. [B. S.]

**CAMPTERIA.** A genus of polypodiaceous Ferns, of the group *Pterides*, distinguished by having the lowermost pairs of veins united, so as to form a series of arcs next the main costa or midrib. The sori are linear continuous and marginal, exactly as in *Pteris*. This group comprises eight or ten species, principally eastern. One of them, however, *C. bicurta*, has a very extended range not only through India and the Eastern Islands to China, but is found also in the Mascaren Islands, South America, the West Indies, Tropical West Africa, and South Africa. [T. M.]

**CAMPTOCARPUS.** A genus of twining glabrous shrubs belonging to the order *Asclepiadaceae*, natives of Madagascar, and the Isle of Bourbon. They have opposite leaves, and axillary few-flowered cymes. The small calyx consists of five sepals; the corolla is five-cleft and reflexed; the five-lobed staminal corona is inserted in the throat of the corolla, and the gynostegium is adnate to its base; the stamens have broad membranaceous filaments, and sagittate glabrous anthers attached to the margin of the stigma; the pollen mass is granular. The two long slender follicles contain many comose seeds. [W. C.]

**CAMPTOSEMA.** A genus of scandent or erect shrubs, belonging to the Pea family, peculiar to South America, and for the most part found in Brazil. Their leaves

are either simple or trifoliate, the leaflets being oblong or elliptical in form, entire, and either smooth or tomentose. The flowers are disposed in axillary racemes; the calyx being tubular, four-parted, and coloured or green; and the corolla from two to three inches long, either yellow or bright red. The pods are stalked, linear, compressed, and contain from three to six seeds. *C. rubicundum*, a native of South Brazil, is a climbing shrub of great length. The leaves are few with long stalks, their leaflets oblong or elliptical, smooth above, and pea-green beneath; the flowers are bright red, in long drooping racemes, like those of a laburnum. It is a beautiful object when in flower, and has long been in cultivation in English gardens. *C. grandiflorum*, also a Brazilian species, has yellow flowers, two to three inches long, disposed in axillary racemes. [A. A. B.]

**CAMPITOSORUS.** A genus of polypodiaceous Ferns, of the group *Aspleniceae*, and of the scolopendroid series, in which the sori are produced in pairs, set face to face on contiguous veins—the reverse of what occurs in the dipazoid series, in which they are set back to back in pairs on the same vein. The present is a small genus consisting of one North American and one Siberian species, both dwarf plants with simple spreading fronds, which are extended into a long narrow tail-like point, where is produced a young plant. The veins join to form a few angular unequal areoles near the midrib, and send out branches towards the margin. The sori, which are linear, and covered by linear indusia, are usually connivent in irregular unequal pairs, but are sometimes more scattered, owing to the irregularity of the venation. The variously-directed irregularly-disposed yet generally opposite pairs of sori form the peculiar features of the genus. [T. M.]

**CAMPOTROPAL.** An orthotropal ovule, curved downwards like a horse shoe, with the sides adherent.

**CAMPYLANTHUS.** A small genus, native of the Canary Isles, Tropical Africa, and India, consisting of branching undershrubs, growing chiefly in the fissures of rocks, having fleshy linear sessile leaves, and small jasmine-like flowers in loose terminal racemes. The calyx is deeply cleft into five linear-lanceolate divisions; the corolla tube is long, cylindrical, and slightly kneeled near the middle, its limb deeply five-lobed. Two stamens on very short filaments rise from the curved portion of the corolla tube, and bear divaricate anthers. The capsule is compressed laterally, and dehiscent septically and septifragally, leaving the placentiferous column free: there are numerous roundish seeds. Webb seems to have satisfactorily referred this singular genus to *Scrophulariaceae*, but so different is it from the other genera of the order, that he has been forced to make for its reception a new tribe which he calls *Campylanthaceae*. [W. G.]

**CAMPYLOBOTRYS.** A genus of *Ochnaceae*, consisting of low-growing Brazilian shrubs, remarkable for their beautiful glossy foliage. They bear flowers with an obovate calyx-tube, having four small linear segments to its limb, and two or three small glands between them; a salver-shaped corolla; four short stamens, with anthers projecting from the short tube of the corolla; a four-cornered ovary, with two many-seeded compartments, and surmounted by a fleshy disc. *C. regalis* has elliptic leaves with a satiny lustre, and a bronzy-green colour, except the main rib and the larger side ones. *C. bicolor* and other species are cultivated in stoves for the beauty of their foliage. They are, however, now regarded as belonging to *Higginia*. [M. T. M.]

**CAMPYLONEURUM.** A genus of simple-fronded polypodiaceous Ferns of the group *Polypodieae*. They have round naked sori as in the other genera of this group, from which they are distinguished by having the principal veins branching from the costa nearly parallel, and united by transverse curved venules, while from the outer side of these are produced two or three short straight veinlets on the middle or point of which the sori are placed. There are about a score of species, all West Indian and South American, and with two exceptions simple-fronded. One of these exceptions is *C. magnificum*, a splendid pinnate Venezuelan fern, of which the pinnae measure eighteen inches long and four inches broad, and bear four rows of sori between the veins. *C. repens* is a well-known illustration of the simple-fronded series. [T. M.]

**CAMPYLOSPERMUM.** When a seed or seed-like fruit is so rolled up as to have a furrow in the longer diameter of one side.

**CAMPYLOSTACHYS.** A genus of *Strobilaceae* confined to South Africa. The only species known, *C. cornua*, is a heath-like bush, about one foot high, with closely set linear pointed leaves, about half an inch long, and terminal roundish spikes of flowers, which are reflexed when the seeds become mature. The flowers are very small, and have a long tube with a four-cleft border. The name *Campylostachys* has reference to the curved spike. [A. A. B.]

**CAMPYLOTROPAL.** An ovule, one of whose sides grows much faster than the other, so that while the chalazm remains at the hilum, the foramen is brought nearly into contact with it.

**CAMPYNEMA.** A genus of doubtful Amaryllids found in Tasmania. It has been associated with *Antigonon* by Herbert, and has been regarded by Brown as intermediate between Amaryllids and Asphodels, coming near to *Melanthaceae*. The only species, *C. lineare*, is a slender herb, about a foot high, with fasciculate fusiform roots; tufted grassy leaves; and one to four terminal inconspicuous yellowish-green flowers. It has a six-leaved perianth

of persistent spreading equal elliptic-lanceolate segments; six stamens; and an inferior three-lobed ovary, containing numerous ovules, and crowned by three recurved styles, terminating in simple stigmas. The name is sometimes written *Campylonema*. [T. M.]

**CAMRUO, CAMRUNGA.** *Averrhoa Carambola*.

**CAMWOOD.** A West African red dye wood produced by *Baphia nitida*.

**CANADA BALSAM FIR.** *Abies balsamea*. Canada Balsam is an oleo-resin obtained from this tree, and is extensively used in medicine and manufactures.

**CANAGONG.** The fruit of *Mesembryanthemum angulaterale*.

**CANALIOULATE.** Channelled, like the petioles of many leaves.

**CANARINA.** A genus of *Campanulaceæ*, containing a glaucous herb from the Canary Islands, which has a tuberous root with milky juice, and a branched stem thickened at the joints, the leaves opposite (rarely in a whorl of three), stalked, hastate-heart-shaped, irregularly toothed, shining above. The flowers are large nodding yellowish (a remarkable feature, as purple, blue, or lilac flowers are usually found in this natural order), solitary at the apex of short leafy axillary branches; calyx-lobes six-cleft, reflexed; corolla bell-shaped, six-toothed; stamens six; ovary inferior, six-celled; style with six stigmas; capsule somewhat fleshy, and as well as the roots and young shoots said to be edible. [J. T. S.]

**CANARIUM.** A genus of *Amyridaceæ*, consisting of trees with compound leaves; the flowers panted, dioecious, having a bell-shaped calyx, with three unequal lobes; three oblong concave petals; six stamens inserted beneath a cup-shaped disc; and a sessile globular ovary, with very short style, and three-lobed stigma. The fruit is a triangular drupe, with three, or, by abortion, one cavity, containing one seed. *C. commune* is cultivated in the Moluccas for its fruits, which are also eaten in Java, and from them an oil is expressed which is used at table when fresh, and for burning in lamps. A gum exudes from the bark which is said to resemble in its properties Balsam of Copaiba. *C. strictum*, according to Dr. Wight, is known in Malabar as the black Dammar tree, in contradistinction to the white Dammar (*Vateria indica*). The resin of Dammar is of a brownish or amber colour. [M. T. M.]

**CANARY CREEPER.** A garden name for *Tropaeolum aduncum*, commonly but wrongly called *T. canariense*.

**CANARY SEED.** The grain of *Phalaris canariensis*, much used as a food for small domesticated birds.

**CANARY WOOD.** The timber of *Persea indica*, and *P. canariensis*.

**CANAVALIA.** About a dozen species of this genus of *Leguminosæ* are known. They are mostly shrubby climbing plants, with slender twining branches, and leaves composed of three leaflets, and are found inhabiting the tropical regions of both hemispheres. The flowers are in racemes produced from the axils of the leaves; their calyx is bell-shaped, two-lipped, with the upper lip largest, and either entire or cut into two lobes, while the lower is three-lobed or entire; their corolla is papilionaceous; and their stamens are united into a column, one of their number being separated for the greater part of its length. The pods are large, with their sides swelled out, and having three elevated ribs or ridges along the upper edge; they contain numerous seeds, which are separated from each other by a quantity of cellular tissue.

*C. gladiata* is commonly found growing in woods in the East Indies, tropical Africa, Mexico, Brazil, the West Indies, &c. The leaves consist of three roundish or egg-shaped leaflets, terminating abruptly in a short point, and varying in size from two to six inches long. The flowers are dark-purple, and succeeded by scimitar-shaped pods, about a foot long, containing numerous red or white seeds, resembling large beans. According to Dr. McFadyen, this plant is called the 'Overlook' by the negroes in Jamaica, who plant it along their provision grounds from a superstitious notion that it 'fulfils the part of a watchman, and, from some dreaded power ascribed to it, protects the property from plunder. Even the better informed adopt the practice, although they themselves may not place confidence in any particular influence which this humble plant can exercise, either in preventing theft, or in punishing it when committed.' [A. S.]

**CANCELLATE.** Composed of veins only, all the parenchyma or intervening web being absent.

**CANCER-ROOT.** An American name for *Epiphyas* and *Conopholis*; also for *Anoploanthus* (*Aphyllon*) *uniflorus*.

**CANCHE.** (Fr.) *Atra*.

**CANDIDUS.** Pure white, but not so white as snow.

**CANDLEBERRY MYRTLE.** The common name for *Myrica*.

**CANDLEBERRY TREE.** *Aleurites triloba*, the nuts of which are commercially called Candle nuts.

**CANDLE TREE.** *Parmentiera cerifera*.

**CANDLEWOOD,** of Jamaica. *Gomphia gulanensis*.

**CANDOLLEA.** A genus of Australian shrubs belonging to *Dilleniaceæ*, with ovate or wedge-shaped leaves, and handsome yellow flowers, which are subsolitary at the tips of the branches; sepals five, oval, mucronate; petals obovate or oboor-

date; stamens polyadelphous; style thread-like; carpels two to five, ovate. [J. T. S.]

The name *Candollea* was also given by Mirbel to a group of Polypodium-like Ferns, now included in *Niphobolus*.

**CANDYTUFT.** Any species of *Iberis*.

**CANE.** A common commercial name for the stems of various grasses, palms, &c. —, **BAMBOO.** *Bambusa arundinacea*. —, **DRAGON.** A kind of Rattan cane. —, **DUMB.** *Dieffenbachia seguine*. —, **GREAT RATTAN.** *Calamus rudens*. —, **GROUND RATTAN.** *Rhapis flabelliformis*. —, **MA-LACCA.** The stem of *Calamus acipionum*, imported for making walking-sticks. —, **RATTAN.** *Calamus Rotang* and its forms, now called *C. Royleanus*, *C. Roxburghii*, &c. —, **REED.** The stem of some grass often forty feet long, from New Orleans, largely imported for making weavers' shuttles. —, **SWEET.** *Andropogon Calamus aromaticus*. —, **SUGAR.** *Saccharum officinarum*. —, **TOBAGO.** The stem of *Bactris minor*, imported for walking-sticks.

**CANE-BRAKE.** The common name for *Arundinaria*.

**CANELLACEÆ.** Two or perhaps three, West Indian or tropical American aromatic shrubs, constituting the two genera *Canella* and *Cinnamodendron*, differ in so many respects from the several orders with which they have been compared, that it has been proposed to class them as a distinct family under the name of *Caneliaceæ*. Their aromatic properties and the structure of their seeds have induced an approximation to *Winteræ* (a tribe of *Magnoliaceæ*), from which, however, their flowers and ovary widely remove them. The stamens, united in a column, with the anthers sessile on the outside, have suggested an affinity with *Guttifera*, *Ternstroemiaceæ*, or even *Sterculiaceæ*; but, upon the whole, it is probably with *Biancheæ* and their allies that *Caneliaceæ* have the nearest connection. They agree with them in their one-celled ovary, with parietal placentas, and they show no marked discrepancy in their foliage, flowers, fruit, or seed, except that the albumen is firmer, with a smaller embryo.

**CANELLA.** The tree yielding *Canella* bark has been placed in various natural groups by different writers. The characters of the genus, in brief, are the presence of three bracts, and five sepals, no petals; twenty stamens united below, and having narrow anthers; a one-celled ovary, with two or three pendulous ovules. The tree is a native of the West Indies, and furnishes a pale orange-coloured bark, with an aromatic odour, which is used as a tonic. The negroes of the West Indies use it as a spice. The plant is frequently grown in botanic gardens. [M. T. M.]

**CANELLA DE OHEIRO.** The volatile oil of *Oreodaphne opifera*.

**CANESCENTS.** Greyish-white; hoary. A term applied to hairy surfaces.

**CANL.** The sun-dried tubers of the Oca, *Ocaila tuberosa*.

**CANKER.** A disease resulting in the slow decay of trees, or other plants attacked by it. See *CARINODES*. [M. J. B.]

**CANKRIENIA.** A genus of *Primulaceæ*, containing a single species from Java, a very beautiful Alpine plant, with erect radical leaves, often half a foot in diameter, verticillate nodding flowers, and erect fruit. The calyx is five-toothed and cup-shaped; the corolla is funnel-shaped, with a five-lobed limb; the five stamens, with short filaments, are inserted in the throat of the corolla opposite to its divisions; the ovary is globose with a rayed apex; the included style remains on the fruit, which is a globular capsule, containing numerous angular seeds. [W. C.]

**CANNA.** See p. 215.

**CANNABINACEÆ.** (*Cannabineæ*, *Hemp-worts*, the Hemp family.) A natural order of Monochlamydeous Dicotyledons, belonging to Lindley's Urtical alliance. Rough-stemmed herbs with watery sap, alternate and lobed leaves having stipules, and small inconspicuous flowers. The plants have some flowers with stamens without pistils, and others with pistils without stamens. The staminate flowers are in clusters called racemes or panicles; calyx herbaceous and scaly; stamens few, opposite the sepals; filaments filiform. Pistillate flowers in spikes or cones, with a single sepal; a one-celled ovary containing a solitary pendulous ovule; stigmas two. Fruit a single-seeded nut; embryo hooked or spiral, without albumen. The plants are natives of the temperate parts of the northern hemisphere in the Old World. They possess narcotic qualities and yield valuable fibres. Hemp is the produce of *Cannabis sativa*. It is imported in large quantities from Russia. The plant grows in the cooler parts of India, and there develops narcotic qualities. These properties seem to reside in the Churrus or resin which covers the leaves. The names of Bhang, Gunjah, and Haschisch are given to the dried plant in different states. What are called Hemp seeds, used for the food of birds, are in reality Hemp fruits, each containing a single seed. *Humulus Lupulus*, the Hop, possesses both tonic and hypnotic properties, i. e. a power of inducing sleep. The scales of the hop-heads are covered with resinous matter, which has an aromatic odour. There are two genera in the order, viz. *Cannabis* and *Humulus*, and two species.

[J. H. B.]

**CANNABINE.** A narcotic gum-resin obtained from the Hemp, *Cannabis sativa*.

**CANNABIS.** The Hemp-plant, *C. sativa*, is the type of the *Cannabineæ*. It is a native of India and Persia, and is generally cultivated, although it is only in hot dry climates that it forms the resin which gives it such value in the estimation of the natives, apart from its fibre-producing

qualities. The dried plant, or portions of it, are sold in the bazaars of India under the name of Gunjah and Bhang, while the resin itself is known as Churra. This resin is collected during the hot season in the following singular manner:—Men clad in leathern dresses run through the hemp fields, brushing through the plants with all possible violence; the soft resin adheres to the leather, and is subsequently scraped off and kneaded into balls. In Nepal, according to Dr. McKinnon, the leathern attire is dispensed with, and 'the resin is gathered on the skin of the naked coolies!' Gunjah is smoked like tobacco; Bhang is not smoked, but pounded with water into a pulp, so as to make a drink: both are stimulant and intoxicating; but the Churra or resin possesses much more powerful properties. In small quantities it produces pleasant excitement, which passes into delirium and catalepsy if the quantity be increased; if still continued a peculiar form of insanity is produced. Many of

go the public that the fast youths are smoking Bhang.' [M. T. M.]

*Cannabis sativa.*

the Asiatics are passionately addicted to the use of this means of intoxication, as the names given to the hemp show—'leaf of delusion,' 'increaser of pleasure,' 'cement of friendship,' &c. &c. A recent traveller in East Africa, Capt. Burton, describes this plant as 'growing before every cottage door.' The Arabs smoke the sun-dried leaf with, and the Africans without, tobacco, in huge pipes. 'It produces a violent cough ending in a kind of scream after a few long puffs, when the smoke is inhaled, and if one man sets the example the others are sure to follow it. These grotesque sounds are probably not wholly natural. Even the boys may be heard practising them as an announcement

The Hemp plant is an annual, growing in ordinary situations from four to ten feet high, but in Italy under very favourable circumstances it sometimes grows as high as twenty feet. The stem is grooved or angular, and, in plants growing singly, frequently much-branched, but when cultivated in masses for the sake of the fibre, it is generally straight and unbranched. It consists of a central pith surrounded by a layer of loose woody and cellular tissue, and enclosed in a thin bark containing the fibre which renders the plant so valuable. Its leaves have long stalks with minute awl-shaped stipules at their bases, and are composed of from five to seven long lance-shaped sharp-pointed leaflets, radiating from the top of the stalk, each leaflet having its margin cut into sharp saw-like teeth. The whole plant has a rough harsh feel from the presence of numerous minute asperities. The flowers are of separate sexes on different plants, the males being produced in racemes and generally crowded together towards the top of the plant or ends of the branches, having a five-parted calyx and five stamens; the females are in short spikes, their calyx consisting merely of a single sepal, rolled round the ovary, but open on one side, and they have two hairy stigmas. The fruit (commonly known as 'hemp seed') is a small greyish-coloured smooth shining nut, containing a single oily seed. Of whatever country Hemp is a native, it is certain that it was known in Europe in very early times, for Herodotus, writing upwards of 3000 years ago, mentions it as being cultivated by the Scythians, who used its fibre for making their garments. At the present day it is cultivated in most parts of Europe; in Arabia, Persia, India, China, and other Asiatic countries; in Egypt, and various other parts of the African continent; and in the United States, Russia and Poland, however, are the two great hemp-producing countries, and it is from them that our supply is mainly derived: but the best quality is produced in Italy; the United States and India likewise send hemp to this country, but the quality is inferior to the Russian. For the production of good fibre the seed is sown close, so as to produce straight stems without branches. The harvesting takes place at two periods; the male being pulled up as soon as it has done flowering, and the female not until the seeds are ripe. After pulling, the leaves are struck off with a wooden sword; the stems are then tied in bundles and steeped in water, or water retted as it is technically termed (two other processes, dew-retting and snow-retting, are sometimes substituted), the object being to loosen the fibre; they are then spread out to dry and bleach: this is called 'gassing,' after which the fibre is detached, either by pulling it off by manual labour, or by breaking the stems in a machine, and afterwards scutching them in a similar

manner to that employed for the preparation of flax.

The uses of Hemp for the manufacture of cordage, canvas, &c., are too well known to require more than a passing allusion. The seeds are used for feeding caged birds, and an oil is expressed from them. The imports of Hemp in 1888 amounted to 739,339 cwts., the computed real value of which was 1,034,377l.; and of Hemp seed, 11,000 quarters; value 24,074l. [A. B.]

**CANNACEÆ.** The Indian-shot family, a natural order of Epigynous Monocotyledons belonging to Lindley's Amomal Alliance. The name of *Marantaceæ* is also given to the order. [J. H. B.]

**CANNA.** The name of a genus of *Marantaceæ* distinguished by the flowers being in panicles; [by the perianth being in two series, the outer segments shorter, the inner alternate; and by the stamens being represented by certain petal-like organs, the outer series of which are all petaloid and functionless, while one of the inner series is two-celled (as shown by Dr Dickie in *Journ. Lin. Soc.*, x. 54) and polliniferous, and united to the edge of a second, which is petaloid, while the third is usually rudimentary]; the style is also petal-like with a linear stigma, and the fruit consists of a capsule covered with rough tubercles externally, and internally divided into three compartments, each of which contains a number of horizontally-placed seeds. The seeds are round, hard, and black, hence the name of Indian Shot, which is applied to the plants.

Many of the species have brightly coloured flowers—yellow, red or orange; the foliage, too, is highly ornamental and characteristic; hence they are favourite plants in cultivation, and produce a striking effect when grouped in beds out of doors during the summer months. The beauty of these plants is not their only feature of interest, as some of them are also of importance from their fleshy underground stems, containing an abundance of starch. *Tous les mois*, a superior kind of arrowroot, the grains of which are very large, is the produce of one of the West Indian species, probably *C. edulis*. The tubers of other species are eaten as a vegetable, while some have slight medicinal properties. In the Brazil the leaves are used for packing purposes, hence the French call these plants *Balister*, from a Spanish word signifying cover. The seeds are also made use of as beads. [M. T. M.]

**CANNE A' SUCRE.** (Fr.) *Saccharum officinarum*. — **DINDE.** *Canna indica*. — **DE JONG.** *Typha latifolia*. — **DE PROVENCE.** *Arundo Donax*.

**CANNEBERGE.** (Fr.) *Oxycoccus palustris*.

**CANNELLIER.** (Fr.) The Cinnamon tree.

**CANNILE'E.** (Fr.) *Lemna minor*.

**CANNOMOIS.** A genus of *Restiaceæ*,

differing from *Restia* in the fruit, which is a hard indehiscent nut; and from *Wildenowia* by having two distinct styles. *C. cephalotes*, the original species, has a rigid stem with numerous short barren stems at the base; flowers in a large ovate terminal head, with ovate acute imbricated bracts. This and another species are from the Cape of Good Hope. [J. T. B.]

**CANNON-BAIL TREE.** *Couroupita guianensis*.

**CANOE BIRCH.** *Betula papyracea*.

**CANOE WOOD.** *Liriodendron tulipifera*.

**CANTERBURY BELL.** *Campanula Medium*, and *C. Trachelium*.

**CANTHARELLUS.** The scientific name of the Chanterelle.

**CANTHIUM.** A genus of *Cinchonaceæ* consisting of spiny rigid plants with solitary fragrant white flowers, having the stamens inserted near the throat of the corolla, and a thread-shaped protruding style terminated by a thick globular or mitre-shaped stigma. The fruit is a two-celled berry. *C. parviflorum*, an Indian plant, makes good fences, while the leaves are occasionally added to curries by the natives; but they have also medicinal properties. One or two species are in cultivation. [M. T. M.]

**CANTUA.** A genus of *Polemoniaceæ*, containing six or eight species, natives of Peru. They are trees or shrubs with alternate fleshy entire or sinuate-dentate leaves, and large showy flowers in corymbs at the termination of the branches, rarely solitary and axillary. The calyx is tubular and five-cleft; the corolla is funnel-shaped with the spreading limb split into five obovate lobes; the five stamens are inserted at the base of the tube, and are more or less exserted; the ovary is three-celled with numerous ovules, and bears a simple style with a trifid stigma; the capsule is coriaceous and three-valved; the seeds have their apex produced into a wing. This genus is nearly related by its capsule and seeds to *Cobæa*, though in habit and inflorescence some of its species approach *Polemonium*. [W. G.]

**CANUS.** Grey-white or hoary. A term applied to hairy surfaces.

**CAOUTCHOUC.** The elastic gummy substance known as India-rubber, which is the inspissated juice of various plants growing in tropical climates in different parts of the world; e.g. *Pinus elastica* and other species of *Moraceæ* plants, *Castilleja elastica* and other *Artocarpææ*, and other *Euphorbiaceæ* plants, *Urosela elastica* and other *Apocynaceæ* plants, &c. The name is also given by the Popayans to the milky juice of *Siphocampylus Caoutchouc*, an elastic gum, very different from the caoutchouc of commerce. [T. M.]

**CAF.** The convex part of an agaric or other similar fungal.

**CAPANZA.** A genus of *Gesneraceae* of the tribe *Beierieae*, consisting of dwarf herbs with subshrubby stems, and opposite oval stalked hairy leaves, from the axils of which spring the flowers two or three together from a common peduncle. The calyx is free, nearly regular, and five-parted. The corolla is irregularly bell-shaped, scarcely curved, somewhat ventricose beneath, with a short limb. There are four didynamous stamens, the filaments of which carry heart-shaped anthers, which are firmly joined together, and form in the mouth of the tube a pale yellow star, with which the stigma is in contact. The ovary is free, surrounded by a disk of five obtuse fleshy lobes. The only species, *C. grandiflora*, a native of New Grenada, grows nearly a foot high, with moderate-sized oval-acuminate leaves, and large showy long-stalked flowers, seated in a tuft at the end of an axillary or terminal peduncle; these flowers are nodding gloxinia-like, with a limb of five broad spreading emarginate lobes, pubescent outside, white, elegantly painted on the inner face of the limb, or less frequently on the tube, with numerous crimson dots arranged in contiguous lines. Dr. Lindley writes the name of this genus *Campana* in *Paxton's Flower Garden*, 1. 91. [T. M.]

**CAPER-WEED.** *Roccella tinctoria*, a dye Lichen, obtained from the Cape de Verd Islands.

**CAPER.** *Capparis spinosa*, the flower buds of which, and of some allied species or varieties, form the well-known condiment of this name, for which the flowers of *Zygophyllum Fabago* are sometimes substituted.

**CAPERONNIER.** (Fr.) *Fragaria elatior*.

**CAPER SPURGE.** *Euphorbia Lathyris*, sometimes called Caper-bush.

**CAPER TREE,** of New South Wales. *Busebeckia arborea*.

**CAPILLACEOUS, CAPILLARY.** Having the form of a thread.

**CAPILLAIRE.** A syrup prepared with *Adiantum Capillus-veneris*.

**CAPILLAIRE.** (Fr.) *Asplenium Trichomanes*. — **DE MONTPELLIER.** *Adiantum Capillus-veneris*. — **DU CANADA.** *Adiantum pedatum*. — **NOIR.** *Asplenium Adiantum-nigrum*.

**CAPILLITIUM.** Entangled filamentary matter in fungals, bearing sporidia.

**CAPILLUS** (adj. **CAPILLARIS**). The breadth of a hair; the twelfth part of a line.

**CAPITÃO DO MATTO.** A common Brazilian name for *Lantana pseudo-thea*.

**CAPITATE.** Pin-headed, as the stigma of a primrose, or as certain hairs. Also growing in heads, or terminal close clusters, as the flowers of composites, &c.

**CAPITULUM.** A close head of sessile flowers. Also a term vaguely applied among fungals to the receptacle, pileus, or peridium.

**CAPNITES.** A section of the genus *Corydalis*. De Candolle employs it in a sense synonymous with *Emboecyna*, but Endlicher used it to designate a part of De Candolle's section *Corynoides*, which includes the species of *Corydalis* without tuberous rootstocks. In this way it is equivalent to *Corydalis* of Bernhardt, and differs from *Capnoides*, as restricted by that author, by having the stem single and branched, and the style persistent. There is, however, no natural division, and it is better to consider all the species of *Corydalis* without tuberous rootstocks, with two separate cotyledons, and with a cup-shaped appendage at the base of the seed, as belonging to the section *Capnoides*. The only British species is the small Climbing Fumitory *Corydalis claviculata*, which has long branched trailing stems, and yellowish flowers in racemes. *C. heda*, often cultivated, and naturalised in several localities, is easily known by its short stems and large bright yellow flowers. [J. T. S.]

**CAPNODIUM.** A curious genus of *Fungi* established by Dr. Montagne to receive a portion of the black smutty parasites which infest the leaves and twigs of shrubs in damp warm climates. It belongs to the division *Ascomycetes*, and is characterised by the abundant creeping black threads which run over the several parts of the plants which it attacks. Shoots from these threads either infest the fruit or are combined to form it. The fruit consists of irregular often elongated and branched cysts, which in the same species contain naked spores, and sporidia enclosed in a sac. Two species belong to the British Flora: *C. Footii*, found on laurel leaves; and *C. elongatum*, in the extreme south-west, on pear trees. Others are the plague of coffee, lemons, olives, and other important plants. In a young state these plants are not distinguishable from *Antennaria*. The stomates of the plants they attack are completely smothered, and direct light almost excluded, so that the functions of the leaves are greatly impeded. No remedy is known when the parasite is once developed. If any is applied, it must be directed to the destruction of the different species of corrus on whose dung or excretions these *Fungi* seem mostly to be developed. Lemons frequently arrive in this country in an unsaleable condition, incrustated more or less completely with a jet black felt, in consequence of the growth either of an *Antennaria* or the spawn of *Capnodium Curi*, which seems to increase greatly after the fruit is packed up for the market. [M. J. B.]

**CAPPARIDACEÆ.** (*Capparidæ*.) A natural order of Thalamifloral Dicotyledons placed in Lindley's Clisal alliance. Herbs, shrubs, or trees with alternate leaves and solitary or clustered flowers; sepals four, imbricate

or valvate; petals four, arranged crosswise, sometimes eight; stamens usually numerous, and a multiple of four placed at the top of a stalk-like receptacle; disk much developed. Ovary usually supported on a stalk and one-celled, with parietal placentas. Fruit either pod-like and opening, or berried; seeds often kidney-shaped, without albumen. The order is divided into two suborders: 1. *Cleomeae*, with dry dehiscent (splitting) fruit. 2. *Cappareae*, fruit a berry. The plants are chiefly tropical. They abound in Africa and India. Some are found in Europe and in Canada. They have pungent and stimulant qualities, and have been recommended in scurvy. In their properties they resemble crucifers. The flower-buds of *Capparis spinosa* constitute capers. *C. aegyptiaca* is considered by some as the hyssop of Scripture. There are thirty-three known genera, and 355 species. Illustrative genera: *Cleome*, *Polanisia*, *Capparis*, *Orateva*. [J. H. B.]

**CAPPARIS.** The genus so called gives its name to the natural order *Capparidaceae*. It consists of shrubs having simple leaves, frequently with two little spines at their base, and showy flowers with a four-parted calyx, four petals, and numerous stamens, succeeded by a berry elevated on a long slender stalk. The most generally known plant of this genus is the common Capar, *C. spinosa*, which grows on walls, etc., in the South of Europe and Mediterranean regions. In its mode of growth it resembles the common bramble. The flower-buds, and in some parts of Italy, the unripe fruits, are pickled in vinegar, and form what are commonly known as capers. They are chiefly imported from Sicily, though the plant is also largely cultivated in some parts of France. All the species

*Capparis spinosa*.

contain, in greater or less quantity, an acrid principle, so that the bark of the root of some of them acts as a blister when applied to the skin; and the fruits of some of the Brazilian species are reported

to be very poisonous. *C. Sodada* is described by Dr. Barth as forming one of the characteristic features in the vegetation of Africa from the desert to the Niger; the small berries have a pungent pepper-like taste, and when dried constitute an important article of food, whilst the roots, when burned, yield no small quantity of salt. Several species are in cultivation in this country, principally natives of warm and tropical climates. [M. T. M.]

**CAPREOLUS.** A tendril.

**CAPRIER COMMUN. (Fr.)** *Capparis spinosa*.

**CAPRIFICATION.** A fertilization of flowers by the aid of insects, as that of the garden fig by a small fly.

**CAPRIFICUS.** The Wild Fig. This, according to Theophrastus and Pliny, is a tree of a wild kind which never ripens its fruit, but has the power of conferring on other trees a virtue which it has not in itself. Since, in accordance with the laws of nature, life springs from putrefaction, from the abortive fruit of the Wild Fig are generated certain winged flies, which, failing to find food in the corruption which gave them birth, fly to a tree of an allied species, and penetrating the fruit of the true fig, make a way for the admission of the heat of the sun and genial air, consume the immature juices, and help the fruit to ripen. To promote this end, the *Caprificus* is planted among fertile fig trees, or cut branches of the one are tied to growing boughs of the other. Fig trees growing in a poor soil exposed to the winds, and especially dust, do not, they say, need this assistance, as the fruit under these circumstances dries up of itself sufficiently to ripen. See Pliny *Nat. Hist.*, lib. xiv. cap. xix., and Theophrastus *de plantis*, end of lib. II. This last passage is curious as containing an early recognition of the presence of sexes in plants. [C. A. J.]

**CAPRIFOLIACEÆ.** (*Lonicereæ*, *Copri-folite*, the Honeysuckle family.) A natural order of gamopetalous Calycifloral Dicotyledons belonging to Lindley's Cinchonal alliance. Shrubs or herbs, often twining, with opposite leaves which have no stipules; calyx adherent to the ovary, its limb four to five-cleft, usually with small leaves (bracts) at its base; corolla superior, regular or irregular; stamens four or five, alternate with the lobes of the corolla. Ovary usually three to five-celled; stigmas three or five. Fruit generally a berry, with one or more cavities, and crowned by the calyx-lobes; albumen fleshy. Natives of the northern parts of Europe, Asia, and America, found sparingly in Northern Africa, and unknown in the Southern hemisphere. Some of the plants are astringent; others have emetic and purgative qualities. Many have showy and fragrant flowers. The suckle or Woodbine (*Lonicera Periclymenum*), one of the plants of this order, twines round the branches of trees, and

often causes confusion in them. The Elder (*Sorbus nigra*), the Gueldres Rose (*Viburnum Opulus*), the Laurustinus (*Viburnum Flans*), the Snowberry (*Symphoricarpos rademousii*), as well as the *Linnaea borealis*, belong to the order. The black berries of the species of *Viburnum*, found on the Himalaya, are eatable and agreeable. There are sixteen genera and 230 species. Illustrative genera: *Linnaea*, *Lonicera*, *Viburnum*, *Sambucus*. [J. H. B.]

**CAPRIFOLIUM.** A genus of well-known twining shrubs giving name to the order *Caprifoliaceae*. No British shrub claims our favourable notice so early in the season as the Honeysuckle (*O. Periclymenum*); for even before the frosts of January have attained their greatest intensity, we may discover in the sheltered wood or hedgebank its wiry stem throwing out tufts of tender green leaves from the extremity of every twig. Later in the season it engages our attention by its twisting stems clinging for support to some lustier neighbour till it has reached air and light, when it asserts its independence, and displays its numerous clusters of trumpet-shaped cream-coloured flowers, tinged with crimson, and shedding a perfume which in sweetness is surpassed by no other British plant. As the coils made by the honeysuckle in its effort to reach the summit of a tree never enlarge, but on the contrary, rather contract as the diameter of its stem increases, it is mischievous to any growing tree round which it twines; it should, therefore, be discouraged in young plantations; but trained against a wall or allowed to twine round a pole or the bole of a full-grown tree, it is harmless and always beautiful. The scarlet berries are clammy to the touch, glutinous and sweet to the taste, but mawkish. In October the woodbine endeavours to impart a grace to the fading year by producing a new crop of flowers, which, though not so luxuriant nor so numerous as the first, are quite as fragrant. Clusters of flowers and of ripe berries may then be found on the same twig, uniting autumn with summer as the early foliage united winter with spring. A variety with leaves sinuated like the oak is not of uncommon occurrence; and another variety, called Dutch Honeysuckle, is valued as a garden plant on account of its extreme fragrance (especially in the evening) and its early flowering.

The Perfoliate Honeysuckle (*O. latifolium*, sometimes called *Lonicera Caprifolium*) resembles the last in habit. It is a native of the middle and South of Europe, and is said to be naturalised in some parts of England. It may be distinguished from the common kind by having its upper leaves united at the base so as to form a kind of cup, and it bears whorls of flowers in the axils of these leaves as well as at the extremity of the shoot.

Among the other cultivated species, *C. Adans.*, a native of America, has very fragrant yellow flowers, which as they fade become

orange-coloured. The Trumpet Honeysuckle (*O. sempervirens*) is an evergreen twining shrub, the upper leaves of which are united at the base (connate), and the flowers, which are scarlet outside, and yellow within, are arranged in several terminal whorls; this is also a native of America, but thrives well in Great Britain in a dry open situation, bearing a profusion of beautiful but scentless flowers from May till August. *O. etruscum* approaches *O. italicum* in habit, but the leaves are more obtuse and downy, and it flowers during a greater portion of the year. In France this species is more frequently cultivated than any other. [C. A. J.]

**CAPSILLA.** A common weed belonging to the cruciferous order, well marked by its heart-shaped pods, which when ripe separate into two boat-shaped valves, each enclosing numerous yellow seeds. There are six known species. *C. Bursa-pastoris*, Shepherd's Purse, is so called from the resemblance of the pods to some ancient form of purse. A native of Europe, it has accompanied Europeans in all their migrations, and established itself wherever they have settled to till the soil. It is a troublesome weed, not refusing to grow and leave seed even in the poorest soil, but luxuriating in the richest. Hence its utilitarian popular name, 'Pickpocket,' is more appropriate perhaps than the sentimental one 'Shepherd's Purse.' When not in flower, it may be distinguished by its radiating leaves, of which the outer lie close pressed to the ground. It is less acid than most of the cruciferous tribe, but was formerly used as a potherb, as is said to be still the custom in some parts of North America. French, *Bourses de Pasteur*; German, *Hirtentasche*. [C. A. J.]

**CAPSICUM.** One of the genera of *Solanaceae*, deriving its name from the Greek word signifying 'to bite,' in allusion to the hot pungent properties possessed by the fruits and seeds. The genus consists of annual or biennial plants, frequently with a somewhat woody and bushy stem; a wheel-shaped corolla; five stamens protruding from the corolla, their anthers converging at their points, and opening by longitudinal slits; and a two to four-celled ovary, becoming, when ripe, a membranous pod containing several seeds. The shape of the fruit varies very much in the different species of the genus.

*C. annuum*, a native originally of South America, but introduced into India and elsewhere, furnishes the fruits known as Chillies; these, as well as the fruits of *C. frutescens*, and several other species or varieties, are used to form Cayenne pepper. For this purpose the ripe fruits are dried in the sun or in an oven, and then ground to powder, which is mixed with a large quantity of wheat flour. The mixed powder is then made into cakes with leaven, these are baked till they are as hard as biscuit, and are then ground and sifted. The Cayenne pepper of the shops is, however, usually largely adulterated

with red lead and other less objectionable substances. The hot taste seems to be due to a peculiar acrid fluid called *capsicin*, which is so pungent that half a grain of it volatilised in a large room, causes all who respire the contained air to cough and sneeze. It is remarkable that the narcotic properties, which are possessed by most of the *Solanaceae* to a greater or less extent, are not present in *Capsicum*—though this is open to some doubt, as it is said that some of the American species have narcotic properties residing in the pulpy matter in which the seeds are imbedded, this pulp being absent in those kinds which are used for their pungent properties.

*Capsicum* fruits are used medicinally, in powder or as a tincture, as an external application, or as a gargle in certain cases of sore throat, particularly those of a malignant character, and internally as a stimulant in cases of impaired digestion, &c. Several kinds are cultivated in this country, as objects of curiosity, and for the sake of their fruits. [M. T. M.]

The species of *Capsicum* are chiefly natives of the East and West Indies, China, Brazil, and Egypt, where they are much esteemed for their pungent fruit and seeds, which, under the name of Cayenne Pepper, or Chillies, form an indispensable condiment, which Nature herself appears to have pointed out to persons resident within the tropics. According to Sir R. Schomburgk, the natives in Guiana eat the fruit of these plants in such abundance as would not be credited by a European unless he were to see it (*Jour. Hort. Soc. II.* 1853). In Jamaica the species most esteemed is the Bonnet Pepper (*C. tetragonum*), the fruits of which are very fleshy, and have a depressed form, like a Scotch bonnet. The shrubby *Capsicum*, or Spur Pepper (*C. frutescens*), is a native of the East Indies, and has been in our gardens since 1654. It forms a dwarf bushy shrub, with white flowers, and bears numerous small oblong obtuse pods, which are very pungent, and in their green and ripe state are used for pickling, as well as for making Chilli vinegar. This is done by merely putting a handful of pods into a bottle, and afterwards filling it with best vinegar, which in several weeks will be fit for use. But the chief purpose for which this species is cultivated is for making Cayenne pepper, which is often prepared by drying the pods on a hot plate, or in a slow oven, and then pounding them in a mortar, and passing them through a hand-mill until the whole is reduced to the finest possible state. After this has been done, the powder is to be sifted through a thin muslin sieve, and preserved in well-corked glass bottles for use. The common annual *Capsicum*, or Guinea Pepper (*C. annuum*), was introduced into Europe by the Spaniards. It was cultivated in England in 1544, and is sufficiently hardy to thrive in summer against a south wall in the open air, and mature its fruit. The colour, direction, and figure of the latter is very

variable—some being yellow, others red, and others black. In a green state they are used for pickling, and when ripe are mixed with tomatoes, &c., to form sauces. They are also dried and ground for use like Cayenne pepper. The Berry-bearing *Capsicum*, or Bird Pepper (*C. baccatum*), is indigenous to both the East and West Indies, and has been grown in this country since 1731. Its pods are erect, roundish, egg-shaped, very pungent, and when ripe are dried and used for the same purposes as those of other kinds of *Capsicum*. They also form one of the chief ingredients in the preparation known in the West Indies as *man-dram*, which is usually resorted to by those affected with loss of appetite or weak digestion, and consists of cucumbers sliced very thin, shallots or onions chopped very fine, a little lime juice and Madeira wine, to which is added a handful of the pods of this pepper, and the whole are then mashed together, and mixed with as much liquid as may be thought necessary. Besides the three species noticed as being the kinds most generally cultivated, there are many other species and varieties occasionally grown for the sake of their pods, all of which yield a warm acrid oil, which acts powerfully on the stomach, and is thought to correct flatulency, and assist digestion. [W. B. B.]

**CAPSOMANIA.** An unnatural development of plants, which may consist either of an excessive multiplication or of such a derangement as impedes their functions. In the first case the unusual demands for nutritive matter cannot be met, and the fruit becomes small and abortive; in the latter, as in green-centred roses, bladder plums, &c., the ovules being imperfect do not come to perfection. [M. J. B.]

**CAPSULE.** Any dry dehiscent seed-vessel. A spurious capsule is any dry seed-vessel that is not dehiscent. Also employed among fungals, to denote certain kinds of perithecia, or receptacles.

**CAPUCHON.** (Fr.) *Arisarum vulgare*.

**CAPUCINE.** (Fr.) *Tropaeolum*.

**CAPUT.** The peridium of certain fungals. — **RADICIS.** The crown of a root. The very short stem, or rather bud, which terminates the roots of herbaceous plants.

**CAQUILLIER.** (Fr.) Oakle.

**CARABIN.** (Fr.) *Fagopyrum esculentum*.

**CARACHICHU.** A Brazilian name for *Solanum nigrum*.

**CARAGAN.** (Fr.) *Caragana*  
cens. — ARGENTE. *Halimic*  
argenteum. — DE LA CHINE. *Caragana*  
*Chamlagu*. — DE SIBIRIE. *Caragana*

**CARAGANA.** The Siberian Pea Tree. Trees or shrubs belonging to the Leguminous order, natives of Siberia and the East, with pinnate leaves of which the midrib terminates in a bristle or spine instead of a leaflet, and axillary flowers, either solitary

or crowded, always single on thin stalks, of a pale yellow colour, with the exception of one species, *C. subata*, in which they are white tinged with red. They are all ornamental or curious. Some of them being natives of Siberia, vegetate like most other Siberian plants, early in the spring, and their delicate planate foliage, of a yellowish green, independently altogether of their flowers, makes a fine appearance about the middle of April, or, in mild seasons, as early as the middle of March. The flowers, which are of a bright yellow, appear about the end of April, in the earliest Siberian species, and those which flower latest, are also latest in coming into leaf. Thus in a group consisting of the different species of this genus, in the climate of London, some plants may be seen, in the month of May, covered with leaves and flowers, and others in which the buds have just begun to expand. The yellow colour prevails in every part of the plants of this genus, even to the roots; and were it not that this colour is so abundant in common productions of the vegetable kingdom, there can be no doubt that the Caragana would be used to afford a yellow dye. *C. arborescens* is a small tree with hard wood and a tough bark, which may be used as a substitute for ropes or cords, as the twigs are for withes. The seeds are good food for poultry, and the leaves are said to contain a blue colouring matter like indigo. *C. spinosa* is a thorny shrub plentiful in China about Pekin, where branches of it are stuck in clay upon the tops of the walls, in order that its spines may prevent people from getting over them. For other species see Loudon's *Arboretum Britannicum*. [C. A. J.]

**CARAGEEN or CARRAGEEN.** A name given in Ireland to *Chondrus crispus*, and some other allied *Alga* when dried and bleached. Vast quantities are collected for sale and supply a useful article for feeding cattle or making jelly for invalids. Its unequivocal sea taste and dour are against its being a perfect substitute for isinglass. There is no doubt, however, that in the sick chamber it is a far better substitute than gelatine, as that has very small, if any, nutritive qualities, a fact perhaps not sufficiently known. [M. J. B.]

**CARAIPA.** A genus of *Ternstroemiaceae*, distinguished among the group having the petals contorted, and the capsule septically dehiscent, by its leaves being alternate, its stamens usually free, with the anthers glanduliferous at the apex, and fixed near the base, and by its having two or three pendulous ovules in each of the three cells of its ovary. The species, about eight in number, grow in Tropical America, and are trees bearing white sweet-scented flowers. The celebrated Balsam of Tamaracari is obtained from *C. fasciculata*, or a closely allied species. This substance, which is of the colour of old port wine, and the consistency of olive oil, is, according to Mr. Spruce (*Journ. Linn. Soc. v. 63*) of great use in the cure of the itch, a single appli-

cation curing the most inveterate cases in twenty-four hours. [T. M.]

**CARAJURA.** A red colouring matter obtained from *Bignonia Chica*.

**CARALLINE.** (Fr.) *Ranunculus glacialis*.

**CARALLUMA.** A genus of *Asclepiadaceae*, containing a few species of fleshy leafless herbaceous plants, natives of India and Arabia. The stems are sparingly branched, erect and four-sided, with teeth at the angles; towards the summit the stem becomes rounded, and from the teeth rise the peduncles bearing at their summits one or more drooping flowers. The calyx is five-parted. The rotate corolla is deeply five-cleft. The gynostegium is slightly exserted, and the bi- or tri-lobed leaves of the staminal corona alternate with the stamens. The roundish pollen masses are capped by a pellucid membrane. The follicles are long and slender, with comose seeds. [W. G.]

**CARAMBOLA TREE.** *Averrhoa Carambola*.

**CARANA PALM.** A South American name for *Mauritia Carana*.

**CARANA RESIN.** A gum resin produced by *Bursera acuminata*, or, according to others, by *Icica Carana* or *Cedrela longifolia*.

**CARAPA.** A small genus of trees with abruptly-pinnate leaves, belonging to the order of Meliads (*Meliaceae*), and native of Tropical America, the West Indies, and Guinea. Their flowers have a calyx of four or sometimes five distinct sepals, and a corolla of the same number of oblong egg-shaped spreading petals; their stamens are united into a tube, the apex of which is divided into eight or ten rounded teeth, bearing the anthers on the inside, between the teeth; and the ovary is four or five-celled, each cell containing four ovules in pairs. The fruit is large and contains numerous oily seeds, and eventually splits into five pieces. *C. guianensis* is a large tree, sixty or eighty feet high, growing plentifully in the forests of Guiana where it is called Carapa and Andiroba. Its leaves are composed of from eight to ten pairs of elliptical lance-shaped leathery shining leaflets; and its fruit is nearly round, and about four inches in diameter. The bark of this tree possesses febrifugal properties, and is also used for tanning. Its timber, called Crab-wood, is obtainable in sticks, fifty feet long by fifteen inches square, and is used in Demerara for making articles of furniture, for shingles, and for the masts and spars of vessels: it is light, having a specific gravity of 0.608, and takes a good polish. By pressure the seeds yield a liquid oil, called Carap oil or Crab oil, suitable for burning in lamps, and which the natives use for anointing their hair; but in this country it hardens into a solid fat. *C. guianensis* is a native of Senegal, and

scarcely differs from the last. Its seeds yield Tallicoonah or Coondil oil, which, besides being used for the same purposes as Crab oil, is employed as a purgative and anthelmintic. [A. S.]

**CARAPIXO DA CALCADA.** A Brazilian name for some species of *Triumfetta*.

**CARATOE.** A West Indian name for *Agave americana*.

**CARAVELLA.** An Indian name for the small black aromatic stimulant seeds of *Cleome pentaphylla*.

**CARAUERU.** A red pigment, so called by the Indians of Guiana, obtained from *Bignonia Chica*.

**CARAWAY.** *Carum Carui*, which yields the well-known carminative fruits called Caraway seeds.

**CARBERRY.** A local name for the Gooseberry, *Ribes Grossularia*.

**CARCERULE.** An indehiscent many-celled superior fruit, such as that of the Huden. Also employed among fungals to denote their spore-case.

**CARCINODES.** A term applied to what is commonly called Canker in trees, which may in general be characterised as a slow decay inducing deformity. The appearances are very different in different plants, and the causes different. The same plant, as the apple, may even exhibit three or four different kinds of Canker. One form arises from the attack of the woolly aphid; a second from the development of bundles of adventitious roots, whose tips decay and harbour moisture, and contaminate the subjacent tissues; a third exhibits itself without any apparent cause in the form of broad dark, or even black, patches, spreading in every direction; while a fourth shows pale depressed streaks which soon become confluent, and eventually kill, first the bark, and then, as a necessary consequence, the underlying wood. The only remedy is to cut out completely the affected parts, and that is not always efficacious. The Canker of the plum and apricot is brought on by gumming. In many cases Canker arises doubtless from the roots penetrating into some ungenial soil, which vitiates the juices and induces death to the weaker cells from which it spreads to surrounding tissue. The rugged appearance is generally due to a struggle between the vital powers of the plant and the diseased action. [M. J. B.]

**CARCINOMA.** A disease in trees when the bark separates, an acrid sap exuding and ulcerating the surrounding parts.

**CARCITHIUM.** The mycelium of certain fungals.

**CAROTTES.** The same as Mycelium.

**CARDAMINE.** An extensive genus of herbaceous Cruciferous plants, distinguished by the nerveless valves of the flat narrow pod, which, when the seeds are

ripe, curl up with an elastic spring from the base upwards, thus scattering the seed. The Cuckoo-flower or Lady's-smock (*C. pratensis*) is a common and very pretty meadow plant, with large lilac flowers. 'They come with the cuckoo,' says Sir J. E. Smith, whence one of their English as well as Latin names (*Flos Cuckoo*); and they cover the meadows as with linen bleaching, which is supposed to be the origin of the other. They are associated with pleasant ideas of spring, and join with the white saxifrage, the cowslip, primrose and harebell, to compose many a rustic nosegay. A double variety is sometimes found wild, which is remarkably prolific, the leaflets producing new plants where they come in contact with the ground, and the flowers, as they wither, sending up stalked flower-bud from their centres. This species is a native of the whole of Europe, Northern Asia, and Arctic America. The flowers and leaves are agreeably pungent, and may be eaten with other herbs in a salad.

*C. hirsuta* is a common weed everywhere, varying in size according to soil and situation, from six to eighteen inches in height. In dry localities it ripens its seeds in March and April, and withers away; but in damper places continues in flower all the summer. The leaves and flowers of this species also form an agreeable salad. This species, and it is said several others, produce young plants from the leaves. All that is necessary is to place them on a moist grassy or mossy surface. Two other British species are less common. The foreign kinds are less ornamental as garden plants than the double variety of *C. pratensis*. French, Cresson; German, *Gauchblume*. [C. A. J.]

**CARDAMOM.** The name applied to the aromatic tonic seeds of various Zingiberaceous plants, as *Allettaria Cardamomum*, and *Amomum Cardamomum*, which, besides their medicinal use, form ingredients in curries, sauces, &c. —, **BASTARD.** *Alpinia Cardamomum*.

**CARDAMOMUM.** The plants formerly so called are now included in *AMOMUM* and *ELETTARIA*; which see. [M. T. M.]

**CARDE.** (Fr.) *Cynara Cardunculus*.

**CARDERE.** (Fr.) *Dipsacus fullonum*.

**CARDIANDRA.** A genus of *Hydrangeaceae*, containing an under-shrub from Japan. It has alternate stalked leaves which are oblong-acute, serrated, and without stipules; and corymbose flowers, those at the margins of the corymb barren and radiant, with a large three-partite petaloid calyx. The fertile flowers have the calyx-tube adhering to the ovary, the limb five-toothed; petals five; stamens numerous, the anthers heart-shaped, from which the genus takes its name; styles three; capsule imperfectly three-celled, opening between the styles. [J. T. S.]

**CARDIAQUE.** (Fr.) *Leonurus Cardiaca*.

**CARDINAL-FLOWER.** *Lobelia cardinalis*; also *Cleome cardinalis*.

**CARDIOCHLENA.** A name proposed for a group of large-growing *Aspidium*-like Ferns, now referred to *Sagaria* [T. M.]

**CARDIOMANES.** An unnecessary name under which it has been proposed to separate *Trichomanes reniforme* from the rest of the genus. [T. M.]

**CARDIONEMA.** A genus of *Illecebraceae* containing a small perennial herb from Mexico, with numerous stems, opposite crowded linear leaves, and small sessile axillary greenish-white flowers, the calyx of which is five-parted, surrounded by an involucre of bracts, five of which are larger than the other, serrulate, terminating in conical points; the petals absent; the stamens five, two sterile, the anthers subrotund; the ovary one-celled with a single ovule, and two revolute styles; the fruit an oblong-ovate utricle. [J. T. S.]

**CARDIOSPERMUM.** A genus of the Soap-wort family (*Sapindaceae*), composed of a number of scandent or climbing shrubs, or herbs having tendrils like the vine. The leaves are twice ternate or very compound, and the leaflets vary much in form; and the flowers, generally small, white or green, and disposed in short axillary racemes, which are furnished below the flowers with two tendrils. The fruit is a three-celled bladder capsule, with few round seeds. The name of the genus is derived from the Greek, and signifies heart-seed, in allusion to the prominent white heart-shaped scars on the seed, which indicate its point of attachment. The common Heartseed (*C. Malicolumbum*), sometimes called also Winter Cherry, or Heart Pea, is a widely distributed plant, found in all tropical countries. Its leaves are twice ternate, the leaflets lanceolate and coarsely toothed. In the Moluccas they are cooked and eaten as a vegetable, and on the Malabar coast are used with castor-oil, and taken internally for lumbago, &c. The root is laxative, diuretic, and demulcent. It is mucilaginous, but has a slightly nauseous taste, and is used in rheumatism. There are upwards of a dozen species known, the greater portion of them natives of South America, but there is no tropical country in which some of the species are not found. [A. A. B.]

**CARD-LEAF TREE.** A West Indian name for *Clusia*.

**CARDON or CARDONETTE.** (Fr.) *Cynara Cardunculus*.

**CARDOON.** *Oynara Cardunculus*.

**CARDOPATIUM.** A genus of perennial thistle-like plants of the Composite family, natives of the Mediterranean region, and also very common in Algeria. They vary in height from six inches to one and a half foot. The leaves are pinnatifid with much divided and spinous segments, and have considerable resemblance to those of the common wayside Thistle (*Cirsium*). The flower-heads are small, and disposed in dense corymbs at

the ends of the branches; the outer scales of the involucre are pinnatifid and spinous, the inner entire and pointed; the florets are of a fine blue colour, all of them tubular, with a five-parted limb, and containing both stamens and pistil. The achenes are covered with villous hairs. According to Gilburt, the *C. corymbosum* is the true black Chameleon of the Ancients; its roots contain an acrid caustic juice, and resemble those of the white chameleon (*Carina gummifera*), but differ in their caustic properties. [A. A. B.]

**CARDO SANTO.** A Brazilian name for *Argemone mexicana*.

**CARDUNCELLUS.** A genus of the thistle group of the Composite family, and closely related to the saffron thistle (*Carthamus tinctorius*), but the achenes, instead of being naked, are crowned with a pappus consisting of numerous bearded hairs of unequal length united at the base into a ring. The stamens also have a tuft of hair on the middle of the filament. There are about nine known species distributed over the Mediterranean region. Some are stemless herbs, with toothed or pinnatifid spiny-pointed leaves lying close to the ground, and sitting in their midst is a large thistle-like flower-head, one to two inches across, containing numerous tubular florets of a blue colour, surrounded by an involucre of many scales, the outer row of which are often leafy, and have spinous teeth. Others have elongated simple or branched stems, one to two feet high, each branch terminating in a flower-head. Some of the species are cultivated in botanic gardens. [A. A. B.]

**CARDUUS.** A genus of compound or Composite flowers, distinguished among the thistle-like plants by having the perfectly smooth fruit crowned by a stalkless tuft of simple deciduous hair. *C. nutans*, a common English species, is distinguished by having the upper part of its stalk almost bare of leaves, and by its large solitary drooping rich purple flowers, which have a strong odour, thought by some to resemble that of the substance from which it derives its name, Must-Thistle. This is sometimes called, but incorrectly, the Scottish Thistle (see *ONOPORDUM*). The Holy Thistle (*C. Marianus*) is well marked by the white veins on its large shiny leaves, fabled to have been produced by a portion of the milk of the Virgin Mary having fallen on them. The other British species are uninteresting weeds. Of the hundred species which the genus comprises, some are cultivated, and are considered ornamental plants. Care, however, should be taken how they are introduced into small gardens, many of the perennial species being exceedingly difficult to eradicate when they have once taken possession of the soil, and all having great facilities of dissemination by means of their downy seeds. The seeds of the thistle tribe are the favourite food of many of the hard-billed small birds, especially the

goldfinch, which derives its name (*Carydalis elegans*) from the plant. The common statement that this bird lines its nest with thistle-down is scarcely accurate; the substance being, in most cases, the down of colt's foot (*Pustillago*), or the cotton from the willow, both of which are procurable at the building season, whereas thistle-down is at that time immature.

*C. lanceolatus* is the emblem of Scotland; the same plant, commonly called Spear Thistle, also forms the badge of the clan Stewart. [C. A. J.]

CAREILLADE. (Fr.) *Hyoscyamus albus*.

CAREYA. A genus of the Myrtle family, and belonging to that section called *Baringtonia*, a group which differs from the true myrtles in having alternate leaves without transparent dots. The plants of this genus are for the most part trees, and are found in India, one species also occurring in North Australia. The leaves are stalked, serrate, and obovate. The flowers are large, red or greenish-yellow, sessile, and forming a short head or spike, or stalked and somewhat corymbose; the calyx four-lobed; the petals, four; the stamens very numerous, their filaments united by their base into a ring; they generally fall in one piece when the flower withers, and have the appearance of a painter's brush. The fruit is a berry, crowned with the remaining calyx-lobes, and in *C. sphaerica* is of the size and form of an orange, yellowish-green in colour, and contains few seeds, embedded in pulp. This species is a native of the Malayan peninsula, where it attains a large size. The bark is ash-like, fibrous, and fit for cordage. The wood of *C. arborea* is used for various purposes, as making boxes, hoops, &c. It is, however, not a valuable timber, as it is liable to split when exposed to the sun, and is not impervious to wet; formerly it was employed for making the drums of the Sepoy corps, being flexible; it takes a good polish, and the colour resembles that of mahogany. The bark is made into a rough cordage; and prepared in a peculiar way, is said to be used in some parts of India as a slow match for firelocks. The fleshy calyx leaves are said to be used for curing colds in Hind. The genus is named in honour of Dr. W. Carey, an Indian botanist, who edited one of the editions of *Roxburgh's Flora Indica*. [A. A. B.]

CARGILLIA. A genus of the Ebony family (*Moraceae*), peculiar to Eastern tropical Australia. The two known species are trees, with alternate leathery oblong obtuse entire leaves. The flowers are small and white, collected in dense clusters in the axils of the leaves, the males and females on the same tree, the former containing eight stamens, surrounded by four petals and a four-parted calyx, and the latter like the males, but having only a few abortive stamens, and a four-lobed ovary, which, when ripe, is a roundish drupe containing few seeds. The genus

differs from its allies in the quaternary arrangement of parts of the flower. The Black Plum of Illawarra (*C. australis*) is a slender tree, from twenty to forty feet in height, and ten to fourteen inches in diameter, the wood of which is close-grained and useful; the fruits are the size of a large plum, and of a dark purple colour. The Grey Plum (*C. arborea*) grows to a height of fifty or a hundred feet, with a diameter of twelve to fourteen inches; its wood is tough and close-grained, but of no beauty. The fruits, which are produced in great abundance, are eaten by the aborigines. [A. A. B.]

CARIACA. A small variety of *Matea*, much esteemed in British Guiana.

CARIBBEAN BARK. The bark of *Myrsine floribundum*.

CARICA. This genus is the type of the order of Papayads (*Papayaceae*). It contains about ten species, natives of tropical America, forming small trees generally without branches, and having large variously-lobed leaves, resembling those of some kinds of palm; all parts exuding an acrid milky juice when wounded. Their flowers are borne in racemes, proceeding from the bases of the leaf-stalks, the males and females being usually on different trees. The males have a funnel-shaped corolla, into the throat of which the ten stamens are inserted in two rows, one above the other; and the females a corolla of five distinct petals. The fruit is fleshy, and does not split open when ripe.

The most remarkable species is *C. Papaya*, called the Papaw-tree. This is now generally acknowledged to be a native of tropical South America, but it is commonly cultivated in most tropical countries, and was at one time supposed to be indigenous to the East Indies. It is a small tree, seldom exceeding twenty feet in height, with a stem about a foot in diameter, tapering gradually to about four or five inches at the summit, and composed of soft spongy wood, mostly hollow in the centre. The leaves are frequently as much as two feet in diameter, and deeply cut into seven broad lobes terminating in sharp points, and having their margins irregularly waved or gnarled; their foot-stalks are about two feet long, and diverge almost horizontally from the stem. The fruit, for which this tree is celebrated, is of a dingy orange-yellow colour, generally of an oblong form, about ten inches long by three or four broad, but shaped like a melon, with projecting angles; it has a thick fleshy rind, like that of a gourd, and contains black wrinkled seeds, arranged in five lines along the whole length of the central cavity. Throughout most of the West Indian Islands the juice of this tree, or an infusion of its fruit or leaves, is reputed to possess the remarkable property of causing a separation of the muscular fibre of animal flesh, and thus rendering the toughest meat tender. It is

indeed, that merely hanging the meat amongst the leaves of the tree will produce the same effect; but in this case it is probable that the result is rather attributable to the high temperature, than to any specific influence exerted by the tree. It is also said that if old hogs or poultry be fed upon the fruits and leaves, their flesh will not fail to be tender. The ripe fruit is seldom eaten raw, although, with the addition of pepper and sugar, it is said to be agreeable. It is generally made into sauce, or preserved in sugar, in the West Indies, and the unripe fruit is either pickled, or boiled and eaten like turnips. Its juice is used by the ladies as a cosmetic, to remove freckles; it is also a powerful vermifuge. And, according to the analysis of Vauquelin, it contains *fibrine*, a substance at one time supposed to be confined to the animal kingdom, but now known to exist in several vegetables. The leaves are employed as a substitute for soap. *C. spinosa* is a branching tree, about twenty feet high, with a spiny stem and branches; native of Guiana and Brazil, where it is called *Chamburn*. Its leaves are deeply cut into seven lobes, like those of *C. Papaya*, but the lobes are quite entire. The juice of this tree is of an exceedingly acrid nature, causing blisters and itching

*Carica Papaya*.

if applied to the skin. The fruits are insipid and are eaten only by a species of ant, neither birds nor other animals touching them; and the flowers have a disgustingly fetid odour. The fruits of some other species, such as *C. citrifolia* and *C. pyrifolia*, are eatable, but insipid. [A. B.]

**CARIE.** (Fr.) *Uredo Caries*.

**CARIES.** This word is used in vegetable pathology to denote decay of the walls of the cells and vessels, whether attended by a greater or less degree of moisture. Life is necessarily limited in all organic structure, and therefore the time must come when the oldest parts of trees must submit to decomposition; and as soon as this commences, it acts as a putrefactive ferment, and involves neighbouring sound tissues.

In plants of shorter duration, decay takes place from various causes, sometimes from mere constitutional peculiarities, sometimes from a cessation of vital functions, sometimes again from atmospheric or other outward agents, and sometimes from parasitic fungi. The rapidity with which the mischief spreads when once set up is exemplified by the potato murrain, and the black spot of orchids; a few days in either case being sometimes sufficient to induce complete decomposition. The decay of fruit, though not due, as is sometimes supposed, to minute fungi, is certainly promoted by their presence, the mere contact of the tissues and parasite being sufficient to set up putrefactive action. [M. J. B.]

**CARILLON.** (Fr.) *Campanula Medium*.

**CARIM-GOLA.** An Indian name for the root of *Monochoria vaginalis*.

**CARINA** (adj. **CARINATE**). A keel. The two anterior petals of a papilionaceous flower, the three anterior in a milkwort, or any such. Also the thin sharp back of certain parts, as that of a glume of *Phalaris*, &c.

**CARINATO-Plicate.** So plaited that each fold is like a keel, as in the peristome of some urn-mosses.

**CARIOPSIS.** A one-celled one-seeded superior fruit, whose pericarp is membranous and united to the seed, as in wheat, maize, and other kinds of corn.

**CARISSA.** A genus of Apocynaceous plants consisting of shrubs with milky juice, and having axillary flower-stalks, some of which bear no flowers, but are reduced to the condition of spines. The corolla is funnel or salver-shaped, sometimes provided with hairs at its throat. Fruit a two-celled berry with few seeds. The species are natives of Asia and tropical Australia.

*C. Carandas*, a common Indian shrub, is used for fence-making, for which its thorny character renders it well adapted. Its fruits are also eaten by the natives as a conserve, &c. Some of the species have medicinal properties, being as bitter as septian. The bark of *C. Xylopteron*, a native of Mauritius and Bourbon, is used by the Creoles in diseases of the urinary organs, while its wood, there called *Bois amère*, has a like reputation. Small cups are made of it in which water or wine is allowed to stand till it acquires the flavour of the wood, as in the bitter cups now so frequently used in this country. [M. T. M.]

**CARLEMANNIA.** A name applied by Ben-  
tham to a genus of Cinchonaceous plants, in honour of Dr. Charles Leman, whose herbarium is now in the possession of the University of Cambridge. The plant is a native of Khasia and the Himalaya, and has leaves with saw-toothed margins, and minute stipules, while the four-parted flower has only two stamens, a circumstance which distinguishes the genus from all its  
[M. T. M.]

**CARLINA.** A genus of prickly herbaceous plants distinguished among the thistle-like group of Compound flowers by having the inner leaves of the calyx or involucre coloured, and of the texture usually called everlasting (scarlose). The species, which closely resemble each other in habit are natives of most parts of Europe, growing on dry commons and sea cliffs. *C. vulgaris*, the only English species, is a common weed about a foot high, on dry heaths and soil which has been long undisturbed, less conspicuous from its dull purple disk than from the radiating straw-coloured involucre, which expands horizontally in dry weather, and becomes erect during rain. This portion of the flower is very durable, retaining its form long after the spiny leaves have been reduced to a skeleton. It preserves its hygrometric properties for a long period, and is sometimes gathered and suspended in the house to serve as a natural weather-gage. Olivier de Sevrès says that this plant received its name after the famous Charlemagne, whose army was cured of the plague by using it medicinally. Linnaeus ascribes the name to the Emperor Charles V., whose army was relieved in Barbary from the same disease by a similar remedy. Several of the species, especially *C. gummifera*, contain an acrid resin in which the medicinal virtue of the plant is supposed to reside. The tender roots of some species are said to be eatable, and of others the flowers furnish a substitute for artichokes. [French, *Carlina*; German, *Eberwurz*.] [O. A. J.]

**CARLINE THISTLE.** The common name for *Carlina*.

**CARLUDOVICA.** A small genus of Screw-pines (*Pandanus*) confined to tropical South America. Some of them have long climbing stems, sending out aerial roots which fasten upon the trunks of trees, or hang down like ropes, whilst others have no stems, and form dense thickets. They have large stiff plaited leaves, deeply cut into from two to five divisions. Their flowers are of separate sexes, and disposed in squares arranged very close together in a spiral manner, and forming cylindrical spikes, which, while young, are enclosed within four leafy bracts (spathe). Each square consists of a female flower surrounded by four males, giving the spikes a tessellated appearance. The males have a calyx cut into numerous lobes, and an indefinite number of stamens; and the females a calyx of four sepals, four barren stamens, and a square-sided ovary surmounted by a cross-like stigma, eventually producing a square-sided berry with numerous seeds.

*C. palmata* is a stemless species, common in shady places all over Panama and along the coasts of New Grenada and Ecuador. Its leaves are shaped and plaited like a fan, and are borne on three-cornered stalks from six to fourteen feet high; they are about four feet in diameter and deeply cut into four or five divisions, each of which

is again cut. The Panama hats commonly worn in America, and now becoming common in this country, are manufactured from these leaves. Those of the best quality are plaited from a single leaf without any joinings, and, as the process sometimes occupies two or three months, their price is very high, a single hat often costing 150 dollars, and cigar-cases of the same material 6l. each. The leaves are cut whilst young, and the stiff parallel veins removed, after which they are slit into shreds, but not separated at the stalk end, and immersed in boiling water for a short time, and then bleached in the sun. [A. B.]

**CARMEL.** The Arab name for *Zygophyllum simplex*.

**CARMICHAELIA.** A genus of New Zealand shrubs belonging to the pea, flowered group of the Leguminous family. The branches are sometimes round, but more commonly flattened and tape-like. The plants when in a seedling condition are furnished with unequally-pinnate leaves, but after they are a few weeks old no more leaves are produced. The flowers are small, very numerous, pink or lilac in colour, and disposed in short racemes. The pods are roundish, slightly turgid, about half an inch long, and contain two or four seeds. They are remarkable in the family because of their having a thin partition (replum) between the valves of the pod, which remains after the valves have fallen; to this partition the seeds are attached. The genus is named in honour of Captain Carmichael, who published an account of the plants of the island Tristan d'Acunha. [A. A. B.]

**CARNATION.** A garden variety of *Dianthus Caryophyllus*. —, SPANISH. *Poniciana pulcherrima*.

**CARNATION TREE.** A garden name for *Kleinia nerifolia*.

**CARNÄUBA.** A Brazilian Palm, *Corypha cerifera*, the leaves of which yield a wax, which is used for making candies.

**CARNEUS.** Flesh-colour; the pale red of roses.

**CARNILLET.** (Fr.) *Silene inflata*.

**CARO.** The fleshy part of fruit. The flesh or tissue of which fungals consist.

**CAROB TREE.** The Algaroba Bean, *Ceratonia Siliqua*.

**CAROLINEA.** The designation given to a genus of *Bombacæ* by the younger Linnaeus in honour of the Princess Sophia Caroline of Baden, a name which he says will always be cherished by botanists. The plants are familiar in our hothouses under this name; but the inexorable law of priority has led botanists generally to adopt that of *PACHIRA*: which see. [T. M.]

**CAROUPE A' SILIQUES.** OR **CAROUPE.** (Fr.) *Ceratonia Siliqua*. — A' MIEL. *Gleditschia triacanthos*.

**CARPADELUM.** An inferior indehiscent two or more-celled fruit with solitary seeds, and carpels which, when ripe, separate from a common axis, as in umbellifers.

**CARPANTHUS.** A synonym of *Asella*.

**CARPEL** (adj. **CARPELLARIS**). One of the rolled-up leaves of which the pistil is composed, whether they are combined or distinct.

**CARPENTERIA.** The name of a Californian shrub belonging to the order *Philadelphaceae*, and having cymes of large white flowers, with a five or six-parted calyx; five to six petals; numerous thread-shaped stamens; and five to seven styles consolidated into one, and terminated by five to seven linear stigmas; capsules attached by their base to the calyx, five to seven-celled, many-seeded. [M. T. M.]

**CARPESUM.** A genus of the Compositae family, remarkable for its distribution only, two of the species being found in South Europe and the Caucasus, and appearing again in the Himalayan Mountains, where the greater portion of the species are found. They are smooth or pubescent erect branching herbs, with ovate or lanceolate toothed leaves. In one section of the genus the flower-heads are small and either solitary or two or three together, in the axils of the leaves, while in the other section they are much larger, single at the ends of the branches, and the outer scales of the involucre are leaf-like and reflexed. The florets in all are dull yellow, tubular, the central ones having both stamens and pistil only. The achenes are beaked, have slender furrows, and are destitute of pappus. [A. A. B.]

**CARPET-WEED.** A common name for *Mollugo*.

**CARPOCERAS.** The name of a group of *Pedakaceae*, now included in *Rogeria*. The same title, given by De Candolle to a section of *Tilasi*, has been adopted as a generic name by Boissier, the section being raised to the position of a genus, and distinguished from the true *Tilasi* by the absence of a wing around the pod. [W. C.]

**CARPOCHASTE.** A genus of the Compositae family, comprising a few slender under-shrubs, all of them natives of New Mexico. Their leaves are opposite, sessile, entire, very narrow, and furnished with glandular dots. The flower-heads purple or white, in loose terminal corymbs; each head with from six to eight florets, all fertile and about an inch in length. The pappus is composed of five to fourteen linear-lanceolate toothed scales, and the achenes have ten slender furrows. Three species are known. [A. A. B.]

**CARPOCOLONIUM.** A free case or receptacle of spores found in certain algae.

**CARPODETES.** A small genus of *Amoebales* allied to *Cobergia*. It has

oblong bulbs, ensiform leaves ten inches long and half an inch wide, and a short flower-scape with a large purple spathe, and bearing from one to three flowers; these are purplish-yellow, drooping, with a slender cylindrical curved tube, a limb of six short regular segments, and a short cup-shaped coronet bearing the six stamens on its margin. The species, *C. recurvata*, is a native of Peru. [T. M.]

**CARPODETUS.** A genus of New Zealand shrubs belonging to the order *Escalloniaceae*. *C. serratus* has much the appearance of a *Rhamnus*, but in its fruit is more closely allied to *Escallonia*. The name of the genus is derived from two Greek words signifying fruit-bound, in allusion to the fruit being girt by the calyx. The principal characteristics are the presence of five petals, touching only by their margins, not overlapping as in allied genera; a viscid stigma; and a leathery succulent fruit, tightly girt with the margin of the calyx, and having four or five compartments containing several ovules. [M. T. M.]

**CARPODINUS.** Climbing shrubs with tendrils, natives of Sierra Leone, and belonging to the order *Apocynaceae*. They have a funnel-shaped downy corolla, with oblique lance-shaped reflexed segments; five sagittate anthers; a globular stigma; and an orange-shaped fruit containing several seeds embedded in pulp. [M. T. M.]

**CARPODONTOS.** A genus of the St. John's-wort family, now generally referred to *EUCRYPTIA*: which see. [A. A. B.]

**CARPOLOBIA.** A genus of the Milk-wort family (*Polygalaceae*). The two known species are natives of West Tropical Africa. They are shrubs or small trees, with alternate ovate acuminate leaves, and short axillary racemes of yellow or white flowers. The calyx is five-leaved; the petals five, one of them keeled and crested at the apex; the stamens eight in number, their filaments united at the base, five of them bearing anthers, the others sterile. The ovary is two-celled with one ovule in each cell, and becomes when ripe a small fleshy somewhat three-angled fruit, containing one seed, which is covered with long silky hairs. [A. A. B.]

**CARPOLOGY.** That part of Botany which treats of the structure of fruits and seeds.

**CARPOLYZA.** A genus of South African Amaryllids, the only species of which, *C. spiralis*, is a neat little plant, having ovate bulbs, short linear filiform leaves, which are twisted or recurved; a scape two to five inches high, singularly twisted in a spiral manner in the lower part, and bearing at the top an umbel of from one to four flowers. These flowers are white, the sepals reddish outside tipped with green; they have a short funnel-shaped tube, and a regular somewhat spreading limb; the filaments are adnate to the tube, the three outer ones shorter, and all bearing

oblong anthers affixed by the base; the style is thick furrowed, triangular, more slender upwards, terminated by a trifid recurved ambriated stigma. [T. M.]

**CARPOMANIA.** This affection, sometimes called Phyllolithes, is scarcely a disease, for the grittiness of pears, medlars, quinces, &c. which the term has in view, is a condition which always exists, and the efforts of the gardener to reduce it as much as possible, are rather efforts to create a disease than to cure one. Grittiness depends upon the deposit of layer after layer of new matter within certain cells, till they become hard like stone. Cultivation has a tendency to make the fruit more juicy, but seldom if ever wholly prevents the formation of these stony cells. In the warm climate of Italy quinces are often so full of them as to become uneatable. A variety is said to exist in Chili completely free from grittiness, but this requires confirmation. [M. J. B.]

**CARPOMORPHA.** Those parts in cryptogamic plants which resemble true fruits without being such receive this name. The spores of lichens.

**CARPOPHORUM.** The stalk of the pistil above or beyond the stamens.

**CARPOPHYLLUM.** The same as Carpel.

**CARPOPODIUM.** A fruit-stalk.

**CARPOPTOSIS.** After the fruit is well-formed and impregnation has taken place, its progress is often suddenly arrested and after a short time it falls off. This frequently depends upon the fact that more fruit is set than the tree is equal to nourish, and the failure of the crop is in consequence either total or partial. If again the supply of nourishment is too great, from want of root-pruning or from any other cause, the demands of the young shoots are often such that the sap is diverted from the fruit, which consequently perishes. In Italy the rice crops are often somewhat similarly affected. In this case, however, the grain acquires a certain degree of maturity, though not its perfect condition, and is so slightly attached to the mother-plant that the slightest breeze shakes it off. It is not a mere case of over-ripeness, which, as in our own corn crops, may be avoided by early reaping. [M. J. B.]

**CARPOSTOMIUM.** The opening into the spore-case of algae.

**CARRADORIA.** A genus of *Globulariaceae* containing a single species, a native of the Italian mountains. It is a glabrous herbaceous plant, with small scattered leaves. The flowers grow in a terminal head; the calyx is subequal; the upper lip of the corolla is simple and linear, and shorter than the lower lip; there is no nectary; the stigma is simple and the scales and palm of the involucre are persistent. In other respects it resembles *Globularia*, from which it has been but recently separated. [W. C.]

**CARRAGEEN.** *Chondrus crispus*; also written Carrageen, under which name its properties are noticed.

**CARRIA.** The name sometimes given to a beautiful Ceylon tree, of the Tea family (*Ternstroemia*). It attains a height of forty to fifty feet, and has entire sessile leaves, which are smooth, of a leathery texture, and elliptical in form; they vary from three to four inches in length, and one to two and a half in breadth. The fine large blood-coloured flowers proceed from the axils of the upper leaves, and are a good deal like those of some single-flowered camellias. The plant is now generally known as *Gordonia speciosa*. [A. A. B.]

**CARRION-FLOWER.** A common garden name for *Stupelia*. Also an American name for *Smilax herbacea*.

**CARROT.** *Daucus Carota*, the garden form of which furnishes the well-known esculent root. — **CANDY** or **CRETAN.** *Aithamania cretensis*. — **DEADLY.** A common name for *Thapsia*. — **NATIVE.** A name given in Tasmania to the tubers of *Geranium parviflorum*.

**CARROT TREE.** *Montsia edulis*.

**CARTHAGINIAN APPLE.** *Punica Granatum*.

**CARTHAME MACULE.** (Fr.) *Silybum Marianum*.

**CARTHAMUS.** A small genus of Compositae, containing two annual species whose flowers grow in heads at the ends of the branches, and are surrounded by numerous leafy bracts (involucre) in numerous rows, the outermost row being broad and spreading out flat, with their edges spiny, the middle ones more upright, of an oval form, and surmounted by an egg-shaped appendage with spiny edges, and the innermost much narrower, quite upright, with their edges entire, but terminated by a sharp spiny point. Each flower is perfect, and has an orange or yellow corolla longer than the involucre, their lower part being imbedded in a dense mass of fringed scales and hairs, but the chief characteristic consists in the absence of the bristles, technically termed pappus. The Safflower plant, or Bastard Saffron (*C. tinctorius*), the Kosumbhla of India and Hoang-tchi of China, is extensively cultivated in India, China, and other parts of Asia, also in Egypt and Southern Europe; but its native country is unknown. It grows about two or three feet high, with a stiff upright whitish stem, branching near the top; and has oval, spiny, sharp-pointed leaves, scattered upon, and their bases half-clasping, the stem. Its fruits are about the size of barleycorns, somewhat four-sided, white and shining, like little shells. Under the name of Safflower, 11,334 cwts. of the flowers of this plant, made up into flat circular cakes about the size of half-crowns, were imported to this country, principally from India, and valued at 105,573l. Safflower contains two colouring

matters, yellow and red, the latter being that for which it is most valued. It is chiefly used for dyeing silk, affording various shades of pink, rose, crimson and scarlet. Mixed with finely-powdered talc it forms the well-known substance called rouge. Another common use of safflower is for adulterating saffron, a more expensive dye stuff. The seeds yield an oil much used in India for burning and for culinary purposes. [A. S.]

**CARTILAGINOUS.** Hard and tough, like the skin of an apple-seed, or a piece of parchment.

**CARTONEMA.** The generic name of one of the spiderworts, characterised by having the filaments of the stamens without any hairs, but somewhat rough; the style or appendage on the seed-vessel thread-like, and bearded at the end. The name is from the Greek, and indicates the bare or shorn stamens. The only known species is *C. spatulatum*, a native of New Holland, a plant covered with scattered hairs, the stem slightly branched, the leaves long and narrow, the flowers blue, arranged in spikes. [G. D.]

**CARUM.** A genus of *Aptaceæ* or *Umbelliferae*, of some importance as producing the Caraway fruits, or seeds as they are improperly termed. The plants have finely cut leaves, and compound umbels, which in the true Caraway have but few bracts surrounding them, or sometimes none at all; petals broad, with a point bent inwards; fruit oval, curved, with five ribs, and one or more channels for volatile oil under each furrow. The Caraway, *C. Carui*, is cultivated in Essex and elsewhere, and may occasionally be found in a half wild condition. The fruits are used for flavouring as they contain an aromatic volatile oil. [M. T. M.]

**CARUNCULA** (adj. **CARUNCULATE**, **CARUNCULAR**). A wart or protuberance round or near the hilum of a seed.

**CARUNCULARIA.** A generic name given to a few plants from the Cape of Good Hope, separated by Haworth from *Stapelia*, but with characteristics scarcely sufficient to establish a new genus. It is consequently used to characterise that section of the genus *Stapelia* which is distinguished by having the staminal corona consisting of five spreading emarginate leaflets, with five blind fleshy clavate appendages in the interior. [W. O.]

**CARUTO.** The Lana dye, a permanent bluish-black obtained in British Guiana from the fruits of *Genipa americana*.

**CARVA.** *Billbergia variegata*.

**CARVI.** (Fr.) *Carum Carui*.

**CARYA.** The generic name of the Hickory trees of America, a genus belonging to the order *Juglandaceæ*, and at one time included with the walnuts under the name of *Juglans*, from which it is distinguished by having the male catkins

produced in threes from a single stalk, each flower having a three-parted calyx, and not more than six stamens; and by the female flowers being destitute of a corolla, and having their four-lobed stigmas sessile upon the ovary. The husk of the fruit, also, splits into four equal-sized pieces, instead of irregularly as in *Juglans*. There are about a dozen species, all of them natives of North America, forming large forest trees. Their timber is coarse-grained, of great strength and toughness, and very heavy; but as it does not bear exposure to the weather, and is extremely liable to the attacks of insects, it is not suitable for building or similar purposes. It is, however, much used where toughness and elasticity are required, such as for barrel-hoops, press-screws, axe-handles, handspikes, &c., and common descriptions of furniture are also made of it. The nuts of some species are eatable, and resemble but do not equal our walnuts.

The Shell-bark, Scaly-bark, or Shag-bark Hickory, *C. alba*, is so called in consequence of its rough shaggy bark peeling off in long narrow strips. It is common throughout the Alleghany mountains from Carolina to New Hampshire, forming a tree eighty or ninety feet in height, with a trunk about two feet in diameter. Its leaves are about twenty inches long, and are composed of five or seven oblong sharp-pointed leaflets, which are hairy beneath, and have sharply saw-toothed edges. The fruit is nearly round, and has an excessively thick rind, enclosing a small white hard-shelled nut, slightly flattened upon two sides, and marked by four elevated angular ridges. These nuts stand second in point of flavour among the hickories, and small quantities of them are sometimes sent to this country. The Bitter-nut or Swamp Hickory, *C. amara*, produces small and somewhat egg-shaped fruits, having a thin fleshy rind, which never becomes hard and woody like that of the others; the nut is nearly round, flat-topped, and tipped with a short sharp point; its kernel is extremely bitter, and is not eaten by any kind of animal. The Pecan or Illinois-nut Hickory, *C. oliviformis*, is a common tree on the banks of the Ohio and Mississippi, attaining a height of sixty or seventy feet; having leaves from a foot to eighteen inches in length, composed of six or seven pairs of leaflets with an odd one, each leaflet being about three inches long, egg-shaped and tapering to a point, and having its edge finely serrated. The nuts of this species are enclosed in a thin woody husk, and are of a light-brown colour, shaped like an olive, and indistinctly marked by four slightly raised longitudinal ridges. They are much superior in flavour to those of the rest of the genus, and are occasionally to be met with in English fruit-shops. A very palatable oil is obtained from them by pressure. The Pig or Hog-nut, or Broom Hickory, *C. porcina*, is a noble tree seventy or eighty feet high, with a trunk upwards of a yard in diameter. Its wood is considered superior to that of the other

species. The leaflets are seven in number, each about four inches long, lance-shaped, and tapering to a fine point, their edges being very regularly cut like the teeth of a saw. The fruit is pear-shaped, and has a thin husk which splits open only at the top end. The nut has a very thick hard shell, and is without the ridges common in other hickory-nuts; its kernel is small and sweet, and is eaten by pigs, squirrels, and other animals. [A. S.]

**CARYOCAR.** One of the two genera forming the order of *Rhizophorales* (*Rhizophoraceæ*), and distinguished by its flowers having free petals, and only four styles, and by its leaves being always opposite; the other genus, *Anthodiscus*, having cohering petals, numerous styles, and often alternate leaves. There are about eight species of *Caryocar*, all large hardwooded trees, growing in the tropical regions of South America. The most interesting is *C. nuciferum*, which produces the Sourari or Butter-nut, occasionally met with in English fruit-shops. These nuts are shaped something like a kidney flattened upon two sides, having an exceedingly hard woody shell, of a rich reddish-brown colour, covered all over with round wart-like protuberances, and enclosing a large white kernel, which has a very pleasant nutty taste, and yields a bland oil by pressure. It is a lofty tree, frequently as much as 100 feet in height, inhabiting the forests of British Guiana, particularly the banks of the rivers Essequibo and Berbice, where its timber, which is very durable, is employed for ship-building. Its leaves are

nuts resemble those of the last; its timber, also, is valuable for ship-building, mill-work, &c. [A. S.]

**CARYODAPHNE.** Under this name are included certain Javanese trees of the Laurel family, possessed of scaly leaf-buds, three-nerved leaves, a funnel-shaped six-cleft perianth, and twelve stamens in four rows, the nine outer ones fertile. Of these stamens the three innermost have a stalked gland on each side of their base, and all have anthers opening by two valves, inwardly in those of the first and second row, outwardly in those of the third row. The three innermost sterile stamens are stalked, with a long pointed lead. The drupe is one-seeded, adherent to the persistent tube of the perianth. *C. densiflora* has a bitter-tasting bark; its leaves are aromatic, and used in spasms of the bowels, &c. [M. T. M.]

**CARYOLOPHA.** A section of the genus *Anchusa*, one of the *Boraginaceæ*, containing *A. sempervivens*, which has a salver-shaped corolla with a very short straight tube, and the ring at the base of the nuts prolonged on the inner side into an appendage, in which it differs from the other sections of the genus. [J. T. S.]

**CARYOPHYLLACEÆ** (*Sileneæ*, *Aisloneæ*, *Queriaceæ*, *Minuartiæ*, *Molluginæ*, *Stenodactylæ*, *Sileneæ*, *Clorocortis*, the Chickweed family). A natural order of Thalamifloral Dicotyledons belonging to Lindley's Silenial alliance. Herbs with stems swollen at the joints, entire and opposite leaves, and a definite (cymose) inflorescence; sepals four to five, separate or cohering; petals four to five, with narrow claws, sometimes wanting; stamens usually as many or twice as many as the petals. Ovary often supported on a stalk (gynophore), usually one-celled, with a free central placenta; styles two to five, with papillæ on their inner surface. Fruit a capsule, opening by two to five valves, or by teeth at the apex, which are twice as many as the stigmas; seeds usually indefinite; embryo curved round mealy albumen. There are three suborders:

1. *Sileneæ*, the Pink tribe, with united sepals opposite the stamens, when the latter are of the same number. 2. *Aisloneæ*, the Chickweed tribe, with separate sepals, bearing the same relation to the stamens as in *Sileneæ*. 3. *Molluginæ*, the Carpetweed tribe, in which the petals are wanting, and the stamens are alternate with the sepals when of the same number. Natives principally of temperate and cold regions. They inhabit mountains, hedges, rocks, and waste places. Humboldt says that clove-worts constitute  $\frac{1}{4}$  of the flowering plants of France,  $\frac{1}{4}$  of those of Germany,  $\frac{1}{4}$  of Lapland, and  $\frac{1}{4}$  of North America. The order has no very marked properties. Some say that the principle, called *saponine*, which is found in some of the plants, has poisonous qualities. There are some showy flowers in the order, such as Pinks and Carnations; but the greater number are mere weeds. The Clove Pink,

*Caryocar tomentosum.*

composed of three broadly lance-shaped or elliptical taper-pointed leaflets, each about six inches long. Its flowers are of great size, and both calyx and corolla are of a deep purplish-brown colour. The fruit is nearly spherical, and about the size of a child's head, containing, when perfect, four of the above-mentioned nuts or seeds; but they are more frequently imperfect and contain only two or three.

Another species, *C. butyrosium*, also a native of Guiana, has white flowers, and leaves composed of five oval-pointed leaflets radiating from a central stalk. It is called Peka by the natives, and its

*Caryophyllus*, is the origin of all the cultivated varieties of carnations, as picotees, bizarres, and flakes. The common Chickweed (*Stellaria media*), and Spurrey (*Spergula arvensis*) used as fodder for sheep, are other examples. There are about sixty genera and 1,100 species. Illustrative genera: *Dianthus*, *Saponaria*, *Silene*, *Lychnis*, *Atsine*, *Arenaria*, *Stellaria*, *Cerastium*, *Molugo*. [J. H. B.]

**CARYOPHYLLACEOUS, CARYOPHYLLATUS.** A corolla whose petals have long distinct claws, as in the clove pink.

**CARYOPHYLLATA.** (Fr.) *Geum urbanum*.

**CARYOPHYLLUS.** One of the genera of *Myrtaceae*, characterised by a long cylindrical calyx, whose limb is four-cleft; four petals adherent at their points; stamens numerous in four parcels; berry oblong, one or two-celled, and as many seeded.

The tree producing the well-known spice called Cloves (*C. aromaticus*) is a handsome evergreen, rising to from fifteen to thirty feet, with large elliptic leaves and purplish flowers arranged in corymbs on short-jointed stalks. The Cloves of commerce

*Caryophyllus aromaticus.*

are the unexpanded flower-buds, and derive their name from the French word *clou*, a nail, in allusion to the shape of the bud with its long calyx tube, and the round knob or head of petals at the top. These buds are collected by hand, or by beating the tree with sticks, when the buds, from the jointed character of their stalks, readily fall, and are received on sheets spread for the purpose. The Cloves are then dried by the sun. For many years the Dutch exercised a strict monopoly in the growth of this spice, by restricting its cultivation to the island of Amboyna, and even there extirpating all but a limited number of the trees; but they are now extensively grown in the West Indies and elsewhere. All parts of the plant are aromatic, from the presence of a volatile oil, but especially the flower-buds, hence its use for culinary purposes. The oil is occa-

sionally used in toothache with the effect of lulling the pain, and as a carminative in medicine. [M. T. M.]

**CARYOTA.** A genus of very elegant lofty Palms (*Palmaceae*) with graceful twic-pinnate leaves, the leaflets of which differ very much from those of other plants of this order. In general the leaflets of pinnate-leaved palms are long, narrow, and tapering upwards to a point; but those of *Caryota*, on the contrary, are comparatively short, tapering to the base, very broad at their top end, where they are jagged as though gnawed by an animal. Nine species of this genus are known, all of them natives of India and the Indian Islands. They have flowers of separate sexes, borne upon the same spike, or sometimes on distinct spikes. The calyx is of three distinct sepals, and the corolla is three-parted; the male flowers have numerous stamens connected together at the base and forming a cup; and the females a one or two-celled ovary, with as many stigmas, and three barren stamens. The fruits are nearly round, somewhat fleshy, and generally of a purplish colour, containing one or two seeds.

*C. urens* is a beautiful tree with a trunk about a foot in diameter, growing to the height of fifty or sixty feet, and surmounted by an elegant crown of gracefully curved leaves. These leaves are eighteen or twenty feet long, and ten or twelve broad, and have a very strong central stalk, the base of which widens out so as to form a kind of sheath round the stem, and leaves a circular mark or scar when it falls away; they have, also, a curious black fibrous material at their base. The leaflets are shaped somewhat like a scalene triangle, one side being very sharply and irregularly jagged. The flower spikes are ten or twelve feet long, and issue from the trunk at the base of the leaves, hanging down like the tail of a horse; they are not produced until the tree has arrived at its full period of growth, and the manner in which the numerous spikes succeed each other is rather singular. The first spike issues from the top of the tree, and after it has done flowering another comes out below it, and so on, a flower-spike being produced from the angle of each leaf-stalk, or from the circular scar left by leaves that have fallen away from the trunk, until the process of flowering reaches the ground, when the tree is exhausted and dies. The fruits are reddish berries about the size of nutmegs, and have a thin, yellow, acrid rind. The tree is a native of Ceylon and many parts of India, particularly Malabar, Bengal and Assam; and it supplies the natives of those countries with several important articles. From its flower-spikes a large quantity of the juice called *Toddy*, or *Palm wine*, is obtained, and this, when boiled, yields very good Jaggery or *Palm sugar*, and also excellent sugar-candy. The whole of the sugar used in Ceylon is obtained from the present and two other palms (*Coosus naci/era*

and *Borassus flabelliformis*), and a particular caste of natives are called *jaggeraros*, on account of their being solely employed in the preparation of this article. Another valuable substance supplied by this tree is

*Caryota urens.*

sago; it is prepared from the central or pithy part of the trunk, and is considered to be quite as good and nutritious as ordinary sago. When made into bread or gruel it forms a large part of the food of the natives. The fibre obtained from the leaf-stalks, called Kittul or Kitool fibre, possesses great strength, and is used for making ropes, brushes, brooms, baskets, &c.; and a woolly kind of scurf scraped off the leaf-stalks is used for caulking boats. The outside part of the stem furnishes a small quantity of hard wood. [A. S.]

**CASCA D'ANTA.** The Brazilian name for the aromatic bark of *Drimys granatensis*.

**CASCA DE LARANJEIRA DA TERRA.** The Brazilian name for a bark supposed to be that of *Esenbeckia febrifuga*.

**CASCA PRECIOSA.** The Portuguese name for *Mespilodaphne pretiosa*.

**CASCARA DE LINGUE.** A Mexican tree bark.

**CASCARA DE PINGUE.** An astrigent Mexican drug, supposed to be obtained from a species of *Curcuma*.

**CASOARILLA.** The aromatic bark of *Ocotea Eleutheria*.

**CASOARILLA.** A name applied by Weddell and other botanists to a genus of *Cinchonaceae*, closely allied to the genus *Cinchona*, but distinguished from it by the fruit splitting into two halves from above downwards, instead of in the reverse manner, as in *Cinchona*, and—which is of more practical importance—by its not containing any of those chemi-

render *Cinchona* so valuable. The shrubs are natives of Peru and Brazil. See also **CROTON.** [M. T. M.]

**CASEARIA.** A large genus of *Samydaceae*, the species of which are found more or less abundant in all tropical countries, but principally in South America. They are small trees or shrubs, with alternate entire or serrated leaves, which in the greater number of the species are furnished with a mixture of round or linear pellucid dots, which can be seen with the aid of a lens, by holding the leaf between the eye and a good light, and serve to distinguish the plants of this genus from those of any other family with which they are likely to be confounded. The flowers are small, white, green, or rose-coloured, generally arranged in little umbels or corymbs, but sometimes sessile. The calyx is of four or five divisions; the petals wanting; the stamens are two, three, or four times as many as the calyx segments, and often the alternate ones are without anthers, and have commonly a tuft of hair in their place. The fruit is a one-celled fleshy capsule, containing few or many seeds.

*C. nimifolia*, a native of Brazil, is used in that country as a remedy against snake-bites. The Brazilians make a drink from the juice of the leaves, and apply the leaves themselves to the wound. M. St. Hilaire asserts that this remedy has been employed with success against the bites of the most venomous serpents. *C. resinifera* has the young flowers enveloped in tears of a greenish resin, which, according to Spruce, is much used for killing cats and dogs; while another species, the *Pao de rato* of the Portuguese, is said to be poisonous to cattle. According to the same authority, *C. javiense* is a constant constituent of all forests of recent growth, from the Amazon's mouth to the Orinoco; its habit is more or less corymbose, and the smooth glossy leaves in size and form somewhat like those of the Spanish chestnut.

*C. seculenta*, a native of the Circar Mountains of India, has purgative roots, which are used by the hill people, who also eat the leaves in stews. The bark of *C. astringens* is used in Brazil for poultices in cases of imperfectly healed ulcers, and is said to be wonderfully efficacious as a cleanser and stimulant of the raw flesh. The leaves of *C. Lingua*, a Brazilian species, are used in decoction in cases of fever or internal inflammation, while those of *C. cascara*, an Indian species, are used in medicated baths, and all the parts of the tree have a bitter taste. Nearly 100 species are enumerated. [A. A. B.]

**CASHAW.** *Prosopis juliflora*.

**CASHEW NUT.** The seed of *Anacardium occidentale*.

**CASIMIROA.** A Mexican genus belonging to the *Aurum*... which it is remarkable for its gro... d flowers, which are borne in... and by its five distinct... whose filaments are

dilated at the base. The fruit is of the size of a large apple. *C. edulis* is a tree, native of, and cultivated in, Mexico. Its fruit, when eaten, has an agreeable taste, but induces sleep, and is unwholesome. The seeds are poisonous. The bark of the tree is bitter, and it, as well as the leaves, and also the seeds, when burnt and reduced to powder, are used medicinally in Mexico. (Boemann.) [M. T. M.]

**CASPARYA.** A genus of Begoniads, consisting of scandent (climbing) plants growing in Peru. The staminate flowers have four, and the pistillate six, sepals; anthers oblong, obtuse, the filaments very short, not united; style deciduous, tripartite, its branches papillose not tortuous. Seed-vessel triangular, with three mucronate horns of a cartilaginous-corky consistence, attenuated at the apex into a short beak; placentas having two lamellae. There are three known species, viz., *C. hirta*, *C. columbiana*, and *C. coccinea*. These species were formerly included in *Begonia*. The genus is named after Dr. Caspary, an eminent botanist of Bonn. [J. H. B.]

**CASSAREEP.** The inspissated juice of the cassava, which is highly antiseptic, and forms the basis of the West Indian Pepper-pot.

**CASSAVA.** The purified fecula of the roots of the Mandioc plant, *Manihot Manihot* (also called *Manihot utilisima* and *Jatropha Manihot*), and *J. Laguncula*. The Cassava juice, though at first poisonous, is rendered harmless by inspissation. In this

others, which open longitudinally; and the ovary is two-celled, with a single ovule in each cell, the style equalling in length the shorter stamens. The drupe has two stones, and is covered by the persistent calyx. This genus is separated from *Tournefortia* by the fruit, which in the latter has a single four-celled stone. [W. C.]

**CASSIA.** This genus is of much importance in a medical point of view, from its producing the well-known drug called senna. It is a member of the Leguminous family (*Fabaceae*); and is known by its five unequal sepals, its five petals of a yellow colour, not papilionaceous, and its ten stamens, three of which are long, four short, and three sterile or abortive, the anthers opening by pores at the top. The species are very numerous, and consist of trees, shrubs, or herbs, with compound pinnated leaves.

The leaflets of several species constitute what are known in medicine as senna leaves. These are of various shapes, and derived from various sources. Alexandrian senna consists of the lance-shaped leaflets of *C. acutifolia*, and the obovate ones of *C. obovata*, united with the leaves of other plants, which latter are readily detected, as the true *Cassia* leaflets, whatever their form, are unequal at the base, from the larger size of one side of the base of the leaflet as compared with the other. The pods of the two species of *Cassia* are also mixed with the leaves, and possess similar properties. East Indian or Tinivelly senna is a very fine kind, and consists of

**CASSE DU LEVANT.** (Fr.) *Acacia Farnesiana*.

**CASSE-LUNETTE.** (Fr.) *Centaurea Cyanus*; and also *Euphrasia officinalis*.

**CASSE-PIERRE.** (Fr.) *Saxifraga granulata*.

**CASSEBEERA.** A genus of polypodiaceous Ferns, belonging to the *Cheilanthes*, and distinguished by having the sori slightly within the margin, though terminal on the veins, and generally combined in pairs or three together on the emarginate lobes, and covered by one indusium. The veins are free but not readily seen. The fronds are coriaceous, three parted, pinnate, or bi-pinnate. There are three or four species, found in Brazil and Buenos Ayres. [T. M.]

**CASSELIA.** A limited genus of small shrubs or herbs from Brazil, belonging to the order *Verbenaceae*. They have membranaceous opposite entire or serrated leaves, and small flowers in lax few-flowered axillary racemes. The calyx is tubular; the corolla funnel-shaped, with a short cylindrical tube, and a five-cleft limb; there are four didynamous stamens hidden in the lower part of the tube, and having very short filaments and two-celled an-

thers. There are other kinds of senna native to and grown in India, Northern Africa, the West Indies, &c. &c., but they are of less importance and value than those above mentioned. The leaves of a North American species, *C. marylandica*, possess similar properties. The heavy nauseous taste and smell of senna are due to a volatile oil, while the purgative effects seem to be due to a chemical substance known as *cathartin*.

The bark and roots of several of the Indian species are used as applications to ulcers and various skin diseases, as well as internally in diabetes and other disorders; they are likewise used for similar purposes in the Mauritius and the West Indies. The seeds of *C. Absus*, a native of Egypt and of India, are bitter, aromatic, and slightly mucilaginous. They are used in Egypt as a remedy for ophthalmia, as are the seeds of *C. auriculata* in India, where also the bark of this shrub is employed by the natives in tanning leather. *C. occidentalis*, a native of both the Indies, is now naturalised in the Mauritius, where the natives use the roasted seeds as a substitute for coffee, and with good effect in certain cases of asthma. It is related that Dr. Livingstone brought the seeds of a plant, which he found cultivated in the

interior of Africa, to the Botanic Garden at the Mauritius, without knowing what the plant was from which they were derived, but stating that the natives prepared and used them as coffee. On investigation the

*Cassia lanceolata.*

turned out to be those of this species used for a like purpose in the Mauritius. *C. fistula*, called the Pudding Pipe Tree from its peculiar pods, is a very handsome tree, with the foliage of the ash, and the inflorescence of the laburnum. It is a native of India, but has been introduced into the West Indies, Northern Africa, &c., whence its pods, called Cassia-pods, are imported. These pods are very unlike those of the other species, being cylindrical, black, woody, one to two feet long, not splitting, but marked by three long furrows, divided in the interior into a number of compartments by means of transverse partitions, which project from the placentae. Each compartment of the fruit contains a single seed, imbedded in pulp. From this peculiarity of the fruit the plant is occasionally placed in a separate genus *Cathartocarpus*. The pulp surrounding the seeds is used as a mild laxative.

Several kinds of this extensive genus are in cultivation, most of them having handsome foliage and conspicuous yellow flowers. [M. T. M.]

**CASSIA BUDE.** A commercial name for the flower-buds of *Onnammom aromaticum*.

**CASSIA, CLOVE.** The bark of *Dicypellum caryophyllatum*. —, POEB. *Ocyris*. — **PURGING.** *Oncis* or *Cathartocarpus fistula*.

**CASSIA-PODS.** The black cylindrical woody pods of *Cassia* or *Cathartocarpus fistula*.

**CASSIDEOUS.** Having the form of a helmet; as the upper sepal in the flower of an aconite.

**CASSINE.** A genus of South African plants belonging to the Spindle-tree family, *Celastraceae*. They are smooth, erect or climbing shrubs, with four-angled twigs, and opposite leathery entire or toothed leaves. The flowers are small and white, disposed in cymes; the calyx four or five-parted; the petals and stamens of a like number. The fruit is a fleshy drupe containing one or two seeds enclosed in a stony shell (putamen) and destitute of an aril. The Lapelhout or Ladlewood of the Cape, *C. Colpoon*, furnishes a useful and handsome wood for cabinet-work and other fancy purposes; it is hard and tough, and when polished, the veining has an exceedingly beautiful appearance; it grows to a height of ten feet, with a diameter of eight to twelve inches. The Hottentot Cherry, *C. Macrocentia*, is a bush of like dimensions. The wood takes a good polish, and is particularly adapted for the manufacture of musical instruments. It is sometimes placed in a separate genus called *Macrocentia*. Seven species of *Cassine* are enumerated. [A. A. B.]

**CASSINIA.** A genus of the Composite family comprising a number of elegant evergreen shrubs, natives of New Holland, Tasmania, New Zealand, and the Auckland Islands. The leaves are small, mostly linear, with the margins rolled backwards. The flower-heads are very numerous and small, white, pink, or yellow in colour, and disposed in terminal corymbs or panicles; the florets all tubular, having both stamens and pistil, or with a few slender female ones near the circumference. The receptacle is furnished with linear scales, like the inner ones of the involucre, and the presence of these scales serves to distinguish the genus (which is named in honour of M. Henri Cassini, an eminent French botanist) from *Oncostemma*, to which it is nearly allied. *C. aurea*, a species with golden yellow flowers and linear leaves, is in cultivation. One species (*C. aculeata*) is found in Tasmania; and three in New Zealand, one of them (*C. Fauxvillei*) occurring also in the Auckland Islands. The remainder are chiefly natives of the eastern portion of Australia. There are about thirteen species known. [A. A. B.]

**CASSIOBERRY BUSH.** *Fidurnum levigatum*.

**CASSIOPE.** A genus of *Ericaceae*, consisting of small Arctic or Alpine evergreen plants, resembling *lycopods* or heaths, with solitary flowers nodding on slender erect peduncles of a white or rose colour. The calyx consists of four or five nearly distinct ovate sepals, and is without bracts; the corolla is campanulate and deeply four to five-cleft; and there are eight to ten stamens, the anthers of which are fixed by their apex, and have ovoid cells, each opening by a large terminal pore, and

bearing a long recurved awn behind. The ovoid capsule has four to five cells and as many valves, with a four to five-lobed placenta pendulous from the summit of the columella, and contains many smooth wingless seeds. [W. C.]

**CASSIPOUREA.** A genus belonging to that section of the Mangrove family called *Legnotideæ*, containing three species, natives of the West Indies, Central America, Venezuela and Guiana. They are trees with opposite entire or serrated leaves, ovate or elliptical in form, and smooth and leathery in texture. The flowers are small, in axillary clusters, and sessile or shortly-stalked; the calyx four or five-lobed; the petals four or five, clawed and fringed like those of a Pink. The fruit is ovoid, about the size of a pea, somewhat fleshy, and containing few seeds. [A. A. B.]

**CASSIS.** (Fr.) *Ribes nigrum*.

**CASSOLETTE.** (Fr.) *Hesperis matronalis*.

**CASSOUMBA.** A pigment made by the Amboynians of the burnt capsules of *Sterculia Balanphas*.

**CASSUVIUM.** The plants formerly so-called are now considered to belong to *ANACARDIUM*: which see. [M. T. M.]

**CASSYTHA.** A curious genus of semi-parasitical leafless thread-like plants, usually considered as a section of the *Lauraceæ*. They grow sometimes in, and receive their entire nourishment from, the soil; but when they come in contact with other plants, they twine round them with their wire-like branches, and, at the place of contact, emit root-like tubercles, by which they derive their future nourishment from the plant to which they are fixed, the roots in the soil dying away. The flowers are small and white, disposed in short spikes which arise from the axils of small scales. The calyx is six-parted. The stamens are petal-like, twelve in number, arranged in four rows; the two external rows perfect, the anthers opening inwards with two recurved lids, the next row smaller and having a pair of glands at the base of each stamen, the anthers opening outwards, while the fourth row is scale-like and abortive. The fruit is about the size of a pea, enclosed in a berried calyx, and contains one seed. The plants of this genus are much like dodders in appearance, and are often called Dodder-laurels. They are native of the East Indies, and are also introduced of leaves and the berried calyx. Some of the Australian species are called Scrub-vines; they grow so thickly in some places as to be almost impenetrable. The white drupes of *C. cuneatiformis*, a N. Australian species, are eatable. *C. albertina*, a common Indian species, is said to be reduced to a paste, mixed with sesamum oil, and used as a head-wash for strengthening the hair; it is also used by the Brahmans of S. India for anointing their butter-milk; and in medicine as a remedy for cleansing in-

veterate ulcers, for which it is prepared by mixing the powdered plant with ginger and butter. The juice mixed with sugar is considered a specific in inflamed eyes. The species are found, more or less, in all tropical countries. [A. A. B.]

**CASSYTHACEÆ.** The genus *Cassytha*, consisting of leafless parasitical twiners, resembling the dodders in habit, is so very different in this respect from the trees or shrubs which constitute the *Lauraceæ*, that it has been proposed to establish it as a distinct family under the name of *Cassythaceæ*. The structure of the flower and fruit presents, however, no difference whatever: the number of parts, and the peculiar anthers are precisely the same, and *Cassytha* is more generally retained as an anomalous genus or tribe of *Lauraceæ*. There are five or six species, natives of the tropical regions both of the New and Old World, where their thread-like or wiry stems attach themselves to herbs or shrubs precisely like our dodders, only on a somewhat larger scale.

**CASTANEA.** The Chestnut. This, the most magnificent tree which reaches perfection in Europe, belongs to the *Corylaceæ*, and is so well known that any statement of its distinctive characters is superfluous. Up to a recent period, it appears to have been an almost generally received opinion that the Chestnut was an indigenous tree in Great Britain. This belief was founded mainly on the supposed fact that Chestnut timber existed in large quantities in old buildings. Evelyn says, 'It hath formerly built a good part of our ancient houses in the city of London, as does yet appear: I had once a very large barn near the city, framed entirely of this timber; and certainly the trees grew not far off, probably in some woods near the town, for in that description of London written by Fitz-Stephen, in the reign of Henry II., he speaks of a very noble and large forest, which grew in the boreal part of it, &c. Other writers, equally deserving of credit, make mention of Chestnut timber being found in old buildings; and, among them, Hasted went so far as to broach a theory that a traffic was anciently carried on between Normandy and England, the latter supplying Chestnut timber in exchange for stone.

That this wood should be found in ancient buildings in very large quantities would carry great weight; but it has recently been discovered that the timber supposed to be Chestnut is in reality a kind of Oak, *Quercus coccifera* or *Dumark Oak*, differing from common oak timber in those very characters which had been fixed on as distinctive of Chestnut. Besides this, Chestnut timber of large dimensions is neither in Great Britain nor the South of Europe found to possess the qualities, strength and durability, which were supposed to have recommended it to the notice of ancient builders. Evelyn's quotation from Fitz-Stephen is a very unhappy one, and the citation of the same passage from

Evelyn, by subsequent writers, is still more unfortunate, for the tree in question is neither described nor even mentioned by name. Evelyn honestly cited the passage as evidence that there formerly existed a great forest near London, in which he thought it probable that Chestnut timber, among other kinds, might grow; and the authors who followed him, perhaps not taking the pains to refer to the original work, and mistaking the drift of his remarks, took it for granted that the tree was mentioned, and considered the evidence conclusive, as well they might. Arguments founded on the facts that trees are individually mentioned as being in existence at periods more or less remote, and that there are in England several places which have long borne a name taken from these trees, e.g. Chesteney, Cheshunt, Cheston, Shesterhunte, Chasteners, &c., and consequently that the trees must have grown there in considerable abundance before such names were given—are far from conclusive; for when it is recollected that the Sycamore was, in the time of Gerard, a 'rare exotic,' and 250 years afterwards as common a hedge tree as the elm, we cannot deny that there was abundance of time between the Roman period and the earliest notice of Chestnut trees in our histories, for those trees to have propagated themselves to any extent. On the whole, then, rather than set aside the positive statement of ancient authors that the Chestnut was first introduced from Asia into Europe by the Greeks, and transported thence into Italy by the Romans, it may with reason be concluded that this tree, though long naturalized in England, is not an aboriginal native, but was introduced by the Romans at a very early period, and in process of time propagated itself so widely as to have raised a doubt whether it was not a really native tree.

Its history may be briefly told as follows:—It was first introduced into Europe from Sardis in Asia Minor, whence it was called the Sardinian Nut, and at a later period Jupiter's Nut, and Husked Nut, from its being enclosed in a husk or rind instead of a shell. Several modern authorities, misquoting a passage in Pliny, attribute its introduction into Italy to Tiberius Caesar, a palpable error, for it is evident from the writings of Virgil that Chestnuts were abundant in Italy long before the time of that emperor. By the Romans it was called *Castanea* from *Castanum*, a town of Magnesia in Thessaly, where it grew in great abundance, and from which it is said that they first brought it. From Italy and Greece it appears to have spread itself over the greater part of temperate Europe, ripening its fruit and sowing itself wherever the vine flourishes. In France, Italy, and Spain it attains a great size. On the Alps and Pyrenees it flourishes at an elevation of between 2,500 and 3,000 feet, the nuts having, perhaps, been carried to those lofty situations by the animals which lay up stores of winter food. It is still more

abundant in Asia Minor, Armenia, and the Caucasus; and it is also found in America as far north as latitude 44°. It ripens its fruit in the warmer parts of Scotland, but rarely, if at all, in Ireland.

The Chestnut blossoms in July, and soon the upper part of the spike bearing the barren flowers withers and drops off, leaving the lower part of the spike still supporting the fertile flowers, with the embryo of the future nuts attached. Towards the end of September the latter begin to ripen, and in October fall to the ground, where they open with valves and expose the ripe nuts. Each case contains from two to five nuts, two or more of which are often mere empty rinds; but all, whether solid or otherwise, have the remains of the flower, in the shape of a few dry bristles, on their points. The Chestnut tree retains its leaves until late in the autumn, when they become of a rich golden hue. Owing to the tufted, and consequently weighty, character of the foliage, and the brittleness of the timber, the tree is liable to be injured by autumnal storms; but the leaves are rarely attacked by insects. The timber of young trees is applied to many useful purposes, but when matured is of little value, being brittle and apt to crack and fly into splinters. In the hop countries the growth of chestnut coppice is much encouraged, poles from this tree and the oak being preferred to all others. French, *Chataigner*; German, *Kastanienbaum*. [C. A. J.]

Theophrastus called it the Eubœan nut, from Eubœa, now Negropont, where it was very abundant; and that being the case, the fruit may have been thence imported into Italy, although the tree, in a wild state, may have previously existed there. Professor Targioni observes that not only have the extensive woods in the Apian Alps, and other parts of the Apennines, every appearance of being really indigenous, but further evidence that woods of this tree existed in Tuscany from very remote times may be found in the number of places which have derived their names from them, such as Castagna, Castagneta, &c. He therefore concludes that we may safely give, as the native country of the wild Chestnut, the South of Europe, from Spain to the Caucasus. Some have even asserted that the tree is a native of Britain; but from the fact of its never being found here in such quantities as to form natural forests, whilst its seed only ripens in warm seasons or favourable localities, this seems very unlikely. It was probably introduced into this country by the Romans for the sake of its fruit. Gregor, in *Morton's Cyclopædia*, says the oldest Chestnut tree in England is supposed to be that at Tortworth, the seat of Earl Duclie, in Gloucestershire. states it to have been remarkable magnitude in the reign of King (1125). It was then called 'the great nut of Tortworth,' from which it may reasonably be presumed to have existed before the Conquest. It bore fruit abun-

dantly in 1788. In 1820 its measurement, five feet from the ground, was fifty-two feet in circumference, so that the diameter, twelve feet, is equal to the width of a moderate-sized room. But these dimensions are small compared with the great Chestnut tree on Mount Etna, which measured 204 feet in circumference. When visited by M. Houel it was undergoing treatment by no means favourable to its prolonged existence. A house was formed in the interior, in which some country people were living; and they had an oven, in which, according to the custom of the country, they dried chestnuts, filberts, and other fruits which they wished to preserve for winter use, using for fuel, when they could find no other, pieces cut with a hatchet from the interior of the tree.

It has been said that the timber in the roof of Westminster Abbey is Spanish Chestnut; but Dr. Lindley has decided that such is not the case, and that Oak, *Quercus sessiliflora*, has been mistaken for it, in this and other old buildings. The timber employed in the construction of the old Louvre at Paris was also supposed to be Chestnut, but on examination by M. Daubenton it was found to be Oak. In this country, where it is certain that very fine oak trees abounded in natural forests, it is not likely that the Spanish Chestnut, requiring to be reared artificially, would be much employed for building purposes. The tree, doubtless, had been originally introduced and grown for the sake of its fruit. It is now, however, cultivated for posts, hop-poles, and hoops.

The fruit is enclosed in a round spiny husk, the inside of which is lined with soft silky pubescence; there are generally three chestnuts in each husk, occasionally more, but sometimes only one. There are many varieties. Some of a very large size are grown in Madeira, but they are not suited for the climate of England. The same remark applies to many of the French varieties, with the exception of the *Marron d'Arras*. The Dorsetshire, Prolific, and Downton are amongst the best adapted for ripening in this climate. The Downton is remarkable for its short-spined husk. Chestnuts, after having been well-dried in the sun, may be kept amongst dry sand in casks. [E. T.]

**CASTANEA DO JOBATA.** *Antiosperma Passiflora*.

**CASTANOSPERMUM.** A genus of plants so named in consequence of the supposed resemblance of the seeds to the sweet chestnuts of Europe. It belongs to the papilionaceous section of Leguminous plants, and contains only one species, remarkable for its large woody long-stalked pods. This plant, *C. australe*, is a native of Moreton Bay, in Queensland, Australia, where it seems a tree forty or fifty feet in height. Its leaves are about a foot in length, pinnate, with an odd leaflet, the leaflets being smooth and of an elliptical form. Its pea-like flowers are produced in racemes, and are of a bright yellow colour:

they have a two-lipped, short-tubed calyx, the upper lip having two, and the lower one three, divisions, and ten free stamens. The fruit is a pendulous cylindrical pod, of a bright brown colour, six or eight inches long, and tapering to both ends: it generally contains four seeds, which are rather larger than chestnuts, and of a roundish shape, but flattened on one side. The continent of Australia is remarkable for the paucity and inferior quality of its indigenous fruits or other esculents, the so-called apples and pears of the colonists being hard, woody, uneatable productions; and the seeds of this tree, called Moreton Bay Chestnuts, are no exception to the rule, for, although they have been extolled, and placed upon an equality with our chestnuts, they are in reality not much superior to acorns, and have an astringent taste: they are improved by roasting, and no doubt proved acceptable to the travellers who first visited Moreton Bay. [A. S.]

**CASTELA.** A genus of tropical shrubs, belonging to the *Simarubaceae*, having foliage like that of the olive, and small unisexual flowers arranged in axillary tufts. The male flowers have eight stamens, inserted beneath the margin of a fleshy eight-lobed disc, those opposite the petals shorter than the rest: the filaments adherent at their base internally to small hairy scales. The female flowers have four ovaries, on a short stalk; the four styles are detached at their origin, but are joined together in the middle for a short distance, and then again detached and recurved. The fruit consists of four fleshy bitter drupes. [M. T. M.]

**CASTELNAVIA.** One of several genera of most curious Brazilian plants, looking like mosses or *Hepaticae*, belonging to the order *Podostemaceae*, and which have been described with the greatest care and ability by M. Tulasne. The present genus consists of plants growing in the rapids, possessing no true leaves but a leaf-like stem or frond, dividing into forked lobes, and cut up at the margins into fringe-like segments. The flowers are either immersed in the substance of the frond, or placed on its margins. Some kinds have linear creeping branched stems, bearing a few linear leaves. The flowers have no calyx or corolla, but a tubular spathe or involucre divided at its margins into several thick thread-like segments; the stamens are two, slightly united one to the other; the fruit consists of a one-celled capsule, with two very unequal valves, surmounted by very long stigmas. [M. T. M.]

**CASTILLEJA.** A genus of *Scrophulariaceae*, natives of America and Asia, containing about forty species of herbaceous plants, with alternate entire or cut-lobed leaves. The pale yellow or purplish flowers are in terminal spikes, with large coloured bracts usually more showy than the flowers. The calyx is tubular, flattened, cleft on the anterior side, and usually on the posterior also; the divisions are entire or

two-lobed. The corolla-tube is included in the calyx; the upper lip is long and narrow, arched, keeled and flattened laterally, and incloses the stamens; the lower lip is short and three-lobed. There are four stamens with oblong-linear unequal anther-cells, the outer attached by the middle, the inner pendulous. The pod contains numerous seeds. [W. O.]

**CASTILLIER.** (Fr.) *Eibes rubrum*.

**CASTILLOA.** A Mexican tree belonging to the *Aricarpacae*, and having male and female flowers alternating one with the other, on the same branch. The male flowers have several stamens, inserted into a hemispherical perianth, consisting of several united scales. The female flowers consist of numerous ovaries in a similar cup. The tree contains a milky juice, yielding caoutchouc. [M. T. M.]

**CASTOR-OIL PLANT.** *Bicinus com-*

**CASTRATUS.** When an important part is missing, as in the case of filaments which have no anthers.

**CASUARINACEÆ.** A group of about a score of species of jointed leafless trees or shrubs, which, in their striated internodes and toothed-ribbed sheaths, have some resemblance to *Equisetum*, whilst in other respects they are allied in some measure to *Ephedra* and the *Conifera*, under which they were formerly classed, and still more with *Myricaceae* and other amen-taceous groups, near to which they are now placed as a small distinct family. Their flowers are unisexual, the males in distinct whorls forming a cylindrical spike; each stamen is enclosed in four scale-like leaflets, the two outer ones considered as bracts, persistent at the base of the stamen, while the two inner ones or sepals, firmly cohering at the tips, are carried upwards by the anthers as the filament is produced. The female flowers are in dense axillary heads without any perianth. The ovaries, sessile within the bracts of the head, are one-celled, with a single ascending ovule, and bear two styles united at the base; the winged nuts are collected in a cone hidden under the thickened bracts. The *Casuarinas* are natives of Australia, of New Caledonia, or of the Indian Archipelago. They are too tender for this climate, but one species is occasionally planted in Southern Europe for its elegant drooping habit.

**CASUARINA.** A group of curious trees constituting of themselves a distinct family, *Casuarinaceae*. They have very much the appearance of gigantic horse-tails (*Equisetaceae*), being trees with thread-like jointed furrowed pendent branches, without leaves, but with small toothed sheaths at the joints. The male flowers are in spikes with two bracts, and two sepals, which adhere at their points and are carried up like a hood by the anther of the single stamen. The female flowers are

on the same plant, and are collected in dense heads; they have no calyx, but; one-celled ovary with one ascending ovule, and two styles: this ripens into a cone of woody bracts enclosing the seed-vessels, which are winged; the seeds are coated densely with spiral vessels.

These singular plants are met with most abundantly in tropical Australia, less frequently in the Indian Islands, New Caledonia, &c. In Australia they are said by Dr. Bennett to be called Oaks. Their sombre appearance causes them to be planted in cemeteries, where 'their branches give out a mournful sighing sound, as the breeze passes over them, waving at the same time their gloomy hearse-like plumes.' The wood is used for fires, as it burns readily, and the ashes retain the heat for a long time. It is much valued for steam-engines, ovens, &c. The timber that is furnished by these trees is valuable for its extreme hardness. From its red colour, it is called in the colonies Beef-wood. The wood of *C. suberosa* is made use of for shingles to cover houses, and for other purposes where lightness, toughness, and durability are required. For further particulars of the Australian species, see Bennett's *Gatherings of a Naturalist in Australia*.

*C. muricata* is a native of Southern India, where it is valued for its showy wood, whose weight, however, forms an objection to its use. The bark furnishes a brown dye. The young branches of some of the species have a grateful acid flavour, much relished by cattle. *C. equisetifolia* is found in the South Sea Islands, the Indian Archipelago, and India. Its bark is astringent, and was formerly used by the South Sea Islanders to dye their cloth. The ashes of the tree yield a quantity of alkali, which is now used in the manufacture of a coarse soap. The wood furnished by it is called iron-wood, from its colour, hardness, and durability. The natives avail themselves of these properties to make clubs, &c., of it. In Australia this species is called the Swamp Oak, though all the species thrive best in damp localities. Dr. Berthold Seemann mentions in a letter to the *Athenæum*, that the Fiji Islanders, or rather those among them that are cannibals, eat human flesh with forks made of the hard wood of a *Casuarina*, while they eat every other kind of food with their fingers. 'Every one of these forks is known by its particular often obscene name, and they are handed down as heir-looms from generation to generation.' So highly were they valued that it was difficult to obtain one. Several species of *Casuarina* are grown in greenhouses for the sake of their singular appearance. [M. T. M.]

**CASSUMUNAR.** The roots of

**CAT.** (Fr.) *Colostrus*

**CATARROSA.** A genus of Grasses belonging to the tribe *Pecticeae*. The genus scarcely differs from *Glyceria*, except in

the circumstance that there are only two florets in each spikelet. The British species, *C. aquatica*, is a handsome grass, but not of much agricultural importance. It is not uncommon in shallow ditches and the furrows of wet fields. [D. M.]

**CATACLESIMUM.** A one-celled, one-seeded fruit, inclosed within a hardened calyx, as in *Mirabilis*.

**CATALEPTIQUE.** (Fr.) *Physostegia*.

**CATALPA.** A genus of *Bignoniaceae* containing four or five species of trees, natives of the West Indies, North America, Japan, and China. They have large simple petiolate and opposite or terno-verticillate leaves, and flowers in terminal panicles. The calyx is deeply two-lipped; the corolla is bell-shaped, with a swollen tube and an undulate five-lobed spreading limb, irregular, and two-lipped. There are two or sometimes four fertile stamens, the one to three others being sterile and rudimentary; the anthers consist of two vertically diverging cells. The ovary is free, bearing a long slender style with a two-lipped stigma. The capsule is very long and slender, nearly cylindrical and two-celled, with the partition contrary to the valves. The seeds are numerous, broadly winged on each side, the wings being cut at their extremities into a fringe. On account of the beautiful and showy panicles of this genus, the species are cultivated in the various countries where they are found, as ornamental trees. They thrive in France and Germany, and when planted in protected situations do well in the south of England, though they are very liable to be cut off by frosts or north-east winds. In London and its neighbourhood they do well. They grow rapidly. The wood is remarkably light of a grayish-white colour, and fine in texture, capable of receiving a brilliant polish, and when properly seasoned is very durable. The bark is said to be tonic, stimulant, and antiseptic; and the honey from its flowers poisonous. [W. C.]

**CATANANCHE.** A genus belonging to the *Cichoraceae* tribe of Compound flowers distinguished by its scarious involucre and the awned chaffy scales which crown its fruit. *C. caryula* is a perennial herbaceous plant with slender stalks, long narrow leaves which are somewhat toothed at the base, and large heads of sky-blue flowers the scaly involucre of which is silvery-white tipped with reddish-brown. It is a native of the south of Europe, and as a border plant flourishes best in a light dry soil in a sheltered situation. Varieties are also cultivated with white or double flowers. *C. hutes* is an annual species with yellow flowers, a native of Candia. French, *Cuspidone*; German, *Rasselblume*. [C. A. J.]

**CATAPETALOUS.** Having the petals slightly united by their inner edge near the base, as in the mallow. A form of *polypetalous*.

**CATAPODIUM.** A genus of Grasses belonging to the tribe *Festuceae*. The

species which were included in this genus are described by Steudel under *Festuca*, in the *Synopsis Graminearum*.

**CATAPUCE.** (Fr.) *Euphorbia Lathyris*.

**CATASETUM.** A numerous genus of fleshy-stemmed terrestrial Orchids from the tropical parts of the New World, where they form masses of considerable extent on decayed leaves, twigs, or other fragments of vegetation. The leaves are plaited and membranous. The flowers, always more or less green, spring in erect or drooping racemes from the base of great oblong fleshy stems, marked by circular scars, showing the places whence leaves have dropped away. The sepals and petals are of a firm leathery texture, sometimes converging into the form of a hood, sometimes spreading backwards. The lip is a fleshy body, not at all jointed with the column; sometimes it assumes the form of a casque, in other cases it is flat, lobed, and broken up into fleshy fringes: the first being characteristic of the original *Catasetum*, the second of what has been called *Myanthus*. The column is an erect fleshy body, terminating in a horn, and bearing about its middle a pair of long deflexed feelers or tendrils, except in a few instances, when the species without feelers have been called *Monachanthus*. In all cases the two fleshy pollen masses are ejected with considerable force by the sudden contraction of a glutinous gland, by which they adhere to surrounding objects. Among the most singular circumstances connected with this genus is the manner in which, upon the same spike, flowers of extremely

*Catasetum Nasc* (flower).

different structure are produced. This was first noticed in Demerara by Sir R. Schomburgk, who published in the *Linn. Soc. Transactions* (xvii. 551) an account of the production of the three supposed genera, *Monachanthus*, *Myanthus*, and *Catasetum*, upon the same spike; and he expressed his opinion that the *Catasetum* was the female of these, because he found it producing seeds abundantly, while *Monachanthus* was uniformly sterile. Afterwards a

similar specimen made its appearance in the garden of his Grace the Duke of Devonshire at Chatsworth. Mr. Darwin confirms that opinion. It has been well observed that 'such cases shake to the foundation all our ideas of the stability of genera and species, and prepare the mind for more startling discoveries than could have been otherwise anticipated.' For, according to the principles employed in botanical classification, no one could have doubted the distinctions between *Monechanthus*, *Myanthus*, and *Catasetum* being real, until the appearance of all their forms upon the same plant effectually dispelled the illusion.

**CATAYA.** A Brazilian name for a recent species of *Polygonum*.

**CATBRIER.** An American name for *Smilax*.

**CATCHOP.** *Mossbryanthemum felinum*.

**CATCHFLY.** The common name for *Silene*.

**CATCHWEED.** The Cleavers, *Galium aparina*.

**CATECHU.** The inspissated juice of the *Areca* palm (*Areca Catechu*), and of *Acacia Catechu*.

**CATENULATE.** Formed of parts united end to end like the links of a chain.

**CATERPILLAR.** A garden name for *Scorpiurus*.

**CATERPILLAR FUNGUS.** See *CORDICONS*. [M. J. B.]

**CATESBÆA.** A genus of West Indian shrubs of the order *Cruciferae*, with small spines above the leaves, and large trumpet-shaped whitish flowers, which are dilated in the throat, and have a four-parted limb; the stamens are four, with their anthers projecting from the corolla; the berry is of the size of a small egg. *C. spinosa* is a dwarf shrub with handsome flowers. Its fruit is yellow, pulpy, and of an agreeable taste. [M. T. M.]

**CATHA.** A genus belonging to the order *Celastraceae*, separated from *Celastrus* on account of some not very well-marked technical characters. Its limits and the number of its species are not strictly defined. They are mostly natives of Africa, forming small shrubs, sometimes with spiny branches, and having simple leaves, from the bases of which small branching heads of flowers are produced. These flowers have a flat five-lobed calyx, five stalkless petals (those of *Celastrus* having short stalks), five stamens, a three-lobed ovary half buried in the large disk which fills the bottom of the flower, and a very short style crowned by three pointed stigmas. The fruit or capsule is three-sided and three-lobed, each cell containing a single seed, and splitting open when the fruit is ripe.

*C. edulis*, formerly *Celastrus edulis*, is a native of Arabia, and is by far the most

interesting species of the genus, its leaves being used by the Arabs in the preparation of a beverage possessing properties analogous to those of tea or coffee. It is a shrub without spines, growing about ten feet in height, and is cultivated by the Arabs in the same ground as coffee. Its leaves are opposite on some branches, and alternate on others, smooth, and about two inches or more in length by an inch in width, of an elliptical form, and having their margins cut into blunt saw-like teeth. The flowers are very small and white. Under the name of *Kât* or *Qafta*, the leaves of this shrub, or, rather, twigs of it with the leaves attached, form a considerable article of commerce amongst the Arabs, large quantities of them being annually brought to Aden from the interior of Arabia, where the plant is cultivated. For the purposes of commerce they are made up into neat closely-pressed bundles of different sizes, according to quality, the best kind being in bundles a foot or fifteen inches long by three inches wide, and consisting of about forty slender twigs, tied together with strips of fibrous bark; each bundle selling at Aden for about two annas (or threepence sterling). The effects produced by a decoction of these leaves are described as resembling those of strong green tea, only more pleasing and agreeable. They are also chewed, either in a green state or when dried, and are said to have the effect of inducing great hilarity of spirits, and an agreeable state of wakefulness, so much so, indeed, that the Arabs who chew them are able to stand sentry all night long without feeling drowsy. The use of *Kât* in Arabia is said to be of great antiquity, and to have preceded that of coffee. Its stimulating effects induced some Arabs to class it with intoxicating substances, the use of which is forbidden by the Koran, but a synod of learned Mussulmans decreed, that, as it did not impair the health or impede the observance of religious duties, but only increased hilarity and good humour, it was lawful to use it. In addition to its powers as a stimulant, the Arabs have a superstitious idea that a twig of it worn in the bosom protects a person from the danger of infection; and that the shrub itself is a preventive against the plague. [A. B.]

**CATHARANTHUS.** A name sometimes met with in gardens, and given to certain shrubby plants belonging to *Vicœa*. [T. M.]

**CATHARTOCARPUS.** The name under which certain species of *Cassia* are sometimes known. [T. M.]

**CATHOARTIA.** Dr. Hooker detected this beautiful plant of the Poppy family in the eastern part of the Himalayan mountains, and named it in honour of Mr. Cathcart, an Indian Judge who investigated the of the Sikkim Himalayas. It is a herb covered with soft yellow hairs, having lobed leaves, and golden drooping flowers, with a hemispherical sessile fruit.

cylindrical capsule, bursting from above downwards into five valves. [M. T. M.]

**CATHEDRA.** A genus of Brazilian trees belonging to *Glacaceæ*, having alternate shortly-stalked elliptical leathery leaves, and small axillary clusters of nearly sessile flowers, with the floral coverings fleshy and green; calyx cup-shaped, petals six, stamens six, disk conspicuous. [J. T. S.]

**CATINGA.** A genus doubtfully referred by its author to the Myrtle family. The two known species are described as trees of French Guiana; their leaves opposite or alternate, stalked, entire, ovate-oblong, with long points, and pellucid dots. The flowers are not known. The fruits are borne in axillary racemes; that of *C. moschata* resembling an orange in size, colour, and form; it is crowned with the four remaining calyx-lobes, and contains one seed, while the outer fleshy part of the fruit is covered with little bladders, containing an essential aromatic oil of a musky odour. *C. fragrans* has a fruit, in size and form like a citron, and has an odour like that of basil. [A. A. B.]

**CATJANG.** The native name of *Cajanus indicus*, a wholesome and much-used kind of pulse.

**CATKIN.** A deciduous spike, consisting of unisexual apetalous flowers. An amentum.

**CATMINT.** The common name for *Nepeta*; especially applied to *N. Cataria*. — **MALABAR.** *Antismone malabarica*.

**CATNEP, or CATNIP.** *Nepeta Cataria*.

**CATOBLASTUS.** Two species of Palms, formerly included in the genus *Iriarteia*, have recently been separated under this name. They are both natives of New Grenada, where they grow together in masses, having trunks from thirty to fifty feet high, distantly marked with circular scars, supported a short distance above the level of the ground upon a tuft of aerial roots, and bearing a crown of pinnate leaves. They differ from *Iriarteia* in the male and female flowers being borne on separate spikes, the males having a small rudimentary ovary in addition to the nine to fifteen stamens, whilst the females have scarcely any rudimentary stamens. The seed, also, has markings like a nutmeg (ruminate), and its embryo is placed upright at the base. [A. S.]

**CATOOMA.** A genus of scandent or climbing shrubs, natives of the tropical parts of S. America, and belonging to the Milkwort family. The leaves are alternate, entire, ovate or oblong, and leathery in texture. The flowers are numerous, disposed in terminal panicles, yellow or greenish white, often with a purple spot on the keel; the calyx five-leaved, the three exterior leaves small; the petals five, one of them large keeled and three-lobed, the two lateral ones small and scale-like, the other two oblong; the stamens eight

in number, united into a tube which cleft above; the anthers one-celled, opening by a terminal pore. The fruit is compressed, wedge-shaped, fleshy, and two-celled, each cell with one seed, which is furnished with long silky hairs. *C. floribunda* is an extensive Brazilian climber, scrambling over the tops of the highest trees, and covering them with a crown of yellowish flowers. Its roots are used against snake-bites. Upwards of a dozen species have been enumerated, but the characters of many of them are very slight indeed. [A. A. B.]

**CATOSTEMMA.** A genus of the Myrtle family (*Myrtaceæ*), and found in British Guiana. The only species known, *C. fragrans*, is a tree fifty feet high. The leaves are alternate, entire, obovate in form, with a little recurved point at the apex, two to four inches long, and one to two broad. The flowers are numerous and fragrant, disposed in fascicles in the axils of the upper leaves, about half an inch across; the calyx cup-shaped, with a two-lobed limb. The plant may be recognised from any other in the family by this character. The petals are five in number, inserted into the upper portion of the calyx tube, and falling away with it after withering; the stamens very numerous, in five parcels. The fruit not known. [A. A. B.]

**CATS-CLAW.** *Dolichos filiformis*. Also *Inga unguis-Cati*.

**CATS-EAR.** The common name for *Hypochaeris*, especially *H. radicata*; applied also to *Gnaphalium dioicum*.

**CATS-MILK.** *Euphorbia helioscopia*.

**CATS-TAIL.** The common name for *Typha*. — **GRASS.** The common name for *Phleum*.

**CATSUP or KETCHUP.** A sauce prepared from mushrooms, walnuts, and other vegetable productions.

**CATTEMUNDOO.** A gum-elastic yielded by *Euphorbia antiquorum*. Sometimes called *Callemundoo*.

**CATTERIDGE TREE.** *Cornus sanguinea*.

**CAT-THYME.** *Teucrium Marum*.

**CATTLEYA.** An extensive genus of Orchids inhabiting Central America and Brazil, where they are found on the bark of trees, and on rocks. The species all form pseudo-bulbs bearing one, or at the most two, fleshy leaves, from the axil of which rise two or more flowers for the most part rose-coloured, but occasionally yellow, or some tint of that colour. These flowers are often among the largest in the orchidaceous order, some being as much as seven inches across from tip to tip of the petals. The finest of all these grand species is *C. Warscewiczii* from the Amazon, whose flowers grow seven together on a raceme eighteen inches long. Next to it stand *C. Mossii*, *lobata*, *crispata*, and *Skinneri*. The species called *C. Schilleriana*

*puttata*, and *granulosa* have thick leathery flowers with crimson spots on a yellowish-green ground. *O. luteola* and *citrina* are wholly yellow. Many of the so-called species in gardens are mere varieties of others. The genus differs from *Lasia* in having four pollen masses instead of eight.

**CATULUS.** A catkin, or amentum, such as is borne by the hazel.

**CATURUS.** The name formerly given to a nettle-like plant of the Spurgewort family, with long cat's-tail-like spikes of small green flowers, which are said to be used in the East Indian Islands either in a conserve or decoction, as a remedy for diarrhoea. The plant is now placed in the genus *ACALYPHA*: which see. [A. A. B.]

**CAUCALIS.** A genus of Umbelliferous plants distinguished by its oblong fruit, ribbed with four rows of hooked prickles, with rough interstices. All the species are herbaceous, natives of Europe and the temperate parts of Asia and Africa. The Bur Parsley, *C. daucoideus*, is a British plant, growing in corn-fields in a chalky soil, and is neither attractive in appearance, nor otherwise interesting. *C. latifolia* was formerly abundant in Cambridgeshire, but is now extinct. The leaves are broader and less divided than is generally the case with the umbelliferous tribe; the flowers are large and rose-coloured. The foreign species are equally unattractive. French, *Caucalide*; German, *Hafeldolde*. [C. A. J.]

**CAUDA** (adj. **CAUDATE**). Any long soft narrow terminal appendage, as that of the corolline lobes of *Strophanthus*, or the lateral sepals of *Cypripedium caudatum*.

**CAUDEX.** The axis of a plant, consisting of stem and root. — **REPENS.** A creeping stem; what is now called a rhizome. — **DESCENDENS.** The root.

**CAUDICULA.** The cartilaginous strap which connects certain kinds of pollen masses to the stigma, as in *Macularia*.

**CAULERPA.** A very beautiful genus of green-seeded *Algae*, abounding in species, and assuming very different forms. The species are almost exclusively natives of warm climates, and occur on sand, on shaded rocks, or in deep water. All have a more or less decided green herbaceous hue, and however complicated may be their growth, or whatever size they may attain, they are formed of a single cell without any transverse divisions, branched and anastomosing in every part of the plant, amidst which a green chlorophyl is produced which ultimately gives rise to minute zoospores. The species are greedily eaten by turtles, of which they form the principal food. The nearest approach which is made to the genus on our coasts, is seen in *Codium*. [M. J. B.]

**CAULET.** (Fr.) A kind of cabbage.

**CAULICLE.** A portion of the axis intermediate in structure and position between

the true root and stem, and called the hypocotyledonary axis, as the trunk of *Wohlbuchia*; the space between the radicle and cotyledons.

**CAULIFLOWER.** A garden variety of *Brassica oleracea*, in which the inflorescence while young is condensed into a depressed fleshy esculent head.

**CAULIGENOUS.** Arising from a stem.

**CAULINE.** Of or belonging to the stem. — **STIPULES.** Such as adhere to the stem as much as to the petiole or leaf.

**CAULINIA.** A section of the genus *Najas*, sometimes considered as distinct on account of the anther being elliptical, one-celled, and without valves; while in *Najas* it is four-sided, four-celled, and opening by four valves, rolling inwards. The only British species of *Najas* (*N. flexilis*, found in lakes in Galway) belongs to *Caulinia*. [J. T. S.]

**CAULIS.** The stem or ascending axis; a name only given to the part in its customary state, growing in the air. — **DELIQUESCENT.** A stem which at a distance above the earth breaks into irregular ramifications, as in the oak. — **EXCURRENS.** A stem which shoots straight from the ground to the summit, having branches on the sides, as in *Abies*.

**CAULOCARPOUS.** A stem which lives many years, repeatedly bearing flowers and fruit; as a shrub or tree.

**CAULOMA.** The stem of a palm-tree. The stem-like portion of the thallus of such algae as some *Fuci*,

**CAULON.** In Greek compounds = stem.

**CAULOPHYLLUM.** A perennial herbaceous plant with tuberous roots, belonging to the order *Berberidaceae*, remarkable for bearing only one leaf on each stem, directly under the cluster of flowers, and terminating the stem, which, consequently, has the appearance of being no more than a leaf-stalk. The true leaf-stalk is divided to the base into three parts, each part having three ovate deeply-cut leaflets. The foliage bears a resemblance to that of *Thalictrum* (hence the specific name *thalictroides*) or *Aquilegia*. The stems are about a foot high; the flowers small, yellowish-green, with six sepals and as many petals and stamens, and are succeeded by deep-blue globose berries, contracted below so as to approach pear-shaped. These berries are called by the Indians Cohosh, and the plant is esteemed medicinal. [This, which is the only species, occurs in North America, in deep rich woods, and also in Japan and Manchuria. It is also called *Pappoose Root*.] [C. A. J.]

**CAUSTIC.** Biting in taste, like Cayenne pepper.

**CAVA or KAWA.** An intoxicating beverage prepared from *Macropiper methusani*.

**CAVERN FERN.** A name given in some books to *Antrophyum*.

**CAVERNULI.** The pores of certain fungi.

**CAVITAS.** The perithecium of certain fungi.

**CAVUS.** The peridium of certain fungi. — **SUPERUS.** The hymenium of certain fungi.

**CAXAPORA DO GENTIO.** A Brazilian name for *Terminolia argentea*.

**CAYENNE PEPPER.** The dried powdered fruits of various species of *Capsicum*. Miller calls it *Cayan Pepper*.

**CEANOTHUS.** Red root. A genus of shrubby plants belonging to the order *Rhamnaceae*, allied to *Euonymus*, with which it agrees in having a three-celled three-seeded pericarp, but the seeds are not enclosed in a membrane (arillus). *C. americanus*, the species most commonly cultivated in English gardens, is a native of N. America, a shrub from two to four feet high, with downy leaves and stems, and small white flowers, which, being produced in great numbers, are very ornamental. They appear in June and July, and are succeeded by bluntly triangular seed-vessels. In America it is commonly known by the name of New Jersey tea, the leaves having been formerly used for the same purpose as those of the Chinese tea-plant, and for which it formed a general substitute during the War of Independence. In Canada it is used for dyeing wool of a nankin or cinnamon colour. Many other species are cultivated, and some of remarkable beauty, which have been introduced of late years, are amongst the finest of half-hardy shrubs. The English name has reference to their large red roots. [C. A. J.]

**CEBADILLA, CEVADILLA.** The seeds of *Asagra officinalis*, from which *veratria* is obtained.

**CEOROPIA.** A genus of large-leaved soft-wooded milky trees, native of tropical South America, and belonging to the order of *Artocarpaceae*. The flowers are extremely minute, and are arranged upon short cylindrical spikes, several of which (sometimes as many as sixty) are enclosed within a large bract, which, however, soon falls away; their calyx is tubular, and rather thicker in the females than the males, the males containing two stamens, and the females a free ovary and short style terminated by a brush-like stigma. The latter are succeeded by short spikes of small fleshy one-seeded fruits. Upwards of twenty-five species are described.

*C. pellata*, the Trumpet-tree of the West Indies and tropical South America, so called because its hollow branches are used for musical instruments, is a very rapid growing tree, having a whitish trunk about a foot in diameter, and attaining a height of upwards of fifty feet, its branches growing out at right-angles, so as to form

a large spreading head, the trunk itself being marked at regular distances by circular scars which indicate the places where leaves once grew, and the hollow inside having transverse partitions corresponding in number and position with them. The leaves are nearly circular, often more than a foot in diameter, and attached to their stalk from a point near the centre, their margins being deeply cut into nine oblong lobes, each of which is tipped with a short point; they are very rough upon the upper side, and thickly covered on the under side with snowy white down. The spikes of fruit are in clusters of from five to fifteen.

The Uaupé Indians, who inhabit the Rio Uaupé, a tributary of the Rio Negro, convert the hollow stems of this tree into a very curious kind of musical instrument, a species of drum, called by them *Ambobas*. They select a trunk four or five inches in diameter, and cut off a piece about four feet long, removing the partitions and rendering the inside smooth by means of fire; they then close up the lower end with leaves beaten down into a hard mass with a pestle, and cut two holes towards the top end, so as to form a handle. These rude instruments are commonly used in the native dances, the performer, holding by the handle, beats the lower end upon the ground, and moves his feet in unison with the sounds thus produced.

The inner bark of the young branches yields a very tough fibre, which is twisted into coarse ropes; and the old bark is employed medicinally as an astringent. The young buds are moreover eaten as a potherb, while the leaves are the common food of the sloth, and the milky juice hardens into caoutchouc. The wood is very light, and is commonly used in the West Indies for making floats for fishing nets; razor-strops are likewise made of it, and when dry the Indians use it for producing fire by means of friction. [A. S.]

**CEDAR.** The common name of various trees, but more especially applied to the Cedar of Lebanon, mentioned below. — **BARBADOS.** *Juniperus barbadensis*. — **BASTARD BARBADOS.** *Ocotelea odorata*; also called the Sweet-scented Barbados Cedar. — **BASTARD.** *Guazuma ulmifolia*; also a common name for *Cedrela*. — **BELMUDA.** *Juniperus bermudiana*. — **GUINANA.** *Ilex alicata*. — **HONDURAS.** *Ocotelea odorata*. — **INDIAN.** *Abies* (or *Cedrus*) *Doodara*. — **JAPAN.** *Cryptomeria japonica*. — **MOUNT ATLAS.** *Abies atlantica*. — **OF GOA.** *Cusperpus indianica*. — **OF LEBANON.** *Abies Cedrus*, often called *Cedrus Libani*. — **OF N. S. WALES.** *Cedrus australis*. — **PRICKLY.** *Cynothoeus Caycedrus*. — **RED.** *Juniperus virginiana*. — **RED, of Australia.** *Cedrus australis*. — **SIAM.** *Juniperus Caycedrus*. — **STINKING.** *Torreya taxifolia*. — **VIRGINIAN.** *Juniperus virginiana*. — **WHITE.** *Cusperpus argentea*. — **WHITE, of Australia.** *Melia australis*. — **WHITE, of B. Guiana.** *Ilex* **WHITE, of Dominica.** *Syzygium*

**CEDAR-APPLES.** The Pennsylvanian name of the curious excrescences on *Juniperus virginiana*, caused by the fungus called *Podisma macrospora*. [M. J. B.]

**CEDRAT.** A variety of the Citron, *Citrus medica*.

**CEDRE BLANC.** (Fr.) *Cupressus thyoides*. — **DES BERMUDEES.** *Juniperus bermudiana*. — **D'ESPAGNE.** *Juniperus thurifera*. — **DE VIRGINIE OR ROUGE.** *Juniperus virginiana*. — **PIQUANT.** *Juniperus Oxycedrus*.

**CEDRELACEÆ.** (*Cedrela*, the *Mahogany* family.) A natural order of Thalamifloral Dicotyledons, belonging to Lindley's Rutal alliance. Trees with alternate pinnate leaves, without stipules. Flowers in panicles; calyx four to five-cleft; petals four to five; stamens eight to ten, inserted on a disk. Ovary three to five-celled. Fruit a capsule opening by valves, which separate from a thick axis; seeds numerous, flat, winged, and anatropal, i. e., with the opening near the hilum, and the chalazæ at the opposite end. There are two suborders: 1. *Swietenia*: filaments of stamens united. 2. *Cedreles*: filaments not united. Natives of the tropics of America and India, very rare in Africa. The plants of this order are generally fragrant, aromatic, and tonic. Many supply compact beautifully-veined timber, such as the Mahogany of tropical America (*Swietenia Mahagoni*), Satin-wood of India (*Chloroxylon Swietenia*), Yellow-wood of New South Wales (*Ocotea canthoxylla*), Red-wood of Coromandel (*Seymida febrifuga*), and the Toon of India or Simal-Kun of the Lepchas (*Cedrela Toona*). A kind of oil is procured from satin-wood; and the barks of *Cedrela febrifuga*, the mahogany tree and others, are used as remedies in intermittent fevers, as well as in dyspeptic complaints. There are nine known genera, and twenty-five species. *Swietenia*, *Seymida*, *Flindersia*, and *Cedrela*, serve as illustrations of the group. [J. H. B.]

**CEDRELA.** A genus of large trees, giving its name to the order *Cedrelaceæ*. They bear compound leaves, regular flowers, five fertile stamens adherent to the stalk which supports the five-celled ovary, and five sterile stamens, which are very small, or altogether absent. The fruit is a capsule bursting by five pieces to liberate the seeds, which are winged. The trees are natives of the tropical parts of Asia and America, and are remarkable for their fine timber, sometimes called Cedar-wood. The trunk of *C. odorata*, a West Indian tree, is sufficiently large to be hollowed out into canoes; this, which is of a brown colour, and has a fragrant odour, is imported under the name of Jamaica or Honduras Cedar. *C. Toona*, a native of Bengal and other parts of India, furnishes timber much like mahogany in appearance but lighter. It is in great request, and is said to be one of the woods known as Chittagong-wood. The bark is very astringent,

and has been found valuable in fevers, dysentery, &c. The flowers are used in some parts of India for producing a red dye. The Red Cedar of Australia, *C. australis*, is now becoming scarce in that colony, the trees having been cut down for the sake of their timber, which was commonly used in the construction of houses. [M. T. M.]

**CEDRINO.** The small Italian Citron.

**CEDRONELLA.** A small genus of *Labiata*, natives of North America, and the Canary Isles. They are sweet-scented perennial herbs, or rarely shrubs, with pale purplish flowers, in spikes or terminal racemes, and having the floral leaves bract-like, and the bracts themselves small and setaceous. The calyx is rather obliquely five-toothed, and many-nerved. The corolla is very large, much expanded at the throat, and two-lipped, with the upper lip flattish or concave, and two-lobed, and the lower three-cleft, spreading, the middle lobe being largest. There are four ascending stamens, the lower pair are shorter than the others; the anthers have two parallel cells. The apex of the style is subequally bifid, with subulate lobes. The nucule is smooth. [W. C.]

**CEDRUS.** The name under which the Cedar of Lebanon, the Deodar or the Indian Cedar, and the Mt. Atlas Cedar, are sometimes separated from other coniferous trees. The characters mainly relied on to distinguish the genus are the evergreen leaves disposed many together in bundles or fascicles, and the erect cones with their carpels separating from the axis. The cedars are now generally included in *Abies*. [T. M.]

**CEINBRA.** (Fr.) *Pinus Cembra*.

**CELANDINE.** The common name for *Chelidonium*. — **LESSER.** *Picaria ranunculoides*. — **TREE.** *Bocconia frutescens*.

**CELASTRACEÆ.** (*Celastrineæ*; *Spindletrees*.) A natural order of Calycifloral polypetalous Dicotyledons belonging to Lindley's Rhamnal alliance. Shrubs or small trees with alternate rarely opposite simple leaves, having stipules which fall off. Flowers in axillary cymes, small, green white or purple; sepals and petals four to five, imbricate, the petals sometimes wanting; stamens four to five, inserted on a large disk, which surrounds the ovary and encloses it. Fruit two to five-celled, capsular or drupaceous (cherry-like); seeds usually with an aril, albuminous, with a large straight embryo. Natives of the warmer parts of Europe, North America, and Asia, far more abundant beyond the tropics than within them. Many inhabit the Cape of Good Hope, some occur in South America, and a few in New Holland. There are two suborders: 1. *Eonymæ*: fruit dry and capsular. 2. *Elæodendree*: fruit drupaceous or cherry-like. The plants of the order are more or less acrid in their properties. Some yield oils. The Spindle-trees have a beautiful scarlet aril, which is derived from the sides of the opening in the seed. The

species of *Euonymus* in America, from their crimson capsules and arils, are called Burning-bush. *Celastrus scandens* from its aspect is denominated Wax-work in North America. The stimulating substance called by the Arabs Khât is procured from *Catha edulis*. The wood of the European spindle-tree is used for cannon gunpowder in France. There are thirty-five known genera, and 280 species. Illustrative genera: *Euonymus*, *Celastrus*, *Eleaodendron*. [J. H. B.]

**CELASTRUS.** A genus which gives its name to the family to which it belongs. It is on the one hand allied to *Euonymus*, from which it differs in its alternate leaves, and on the other to *Catha*, which embraces spiny shrubs, whose seeds are furnished with a small aril; whilst *Celastrus* is composed of small unarmed scandent shrubs or trees, having a large aril to their seeds. Their leaves are alternate, entire or serrated with minute stipules. The flowers are small, green or white, and disposed in terminal racemes or panicles. The name of the genus is derived from the Greek, signifying the latter season. The ancients considered the holly, the genista, and the celastrus, the trees which ripened their fruit latest in the season. The *Celastrus* of the ancients is, however, supposed to have been a kind of *Euonymus*. *C. scandens* is a climbing North American shrub, popularly known as Bitter-sweet or Wax-work. The capsules are orange-coloured when mature, and the seeds reddish-brown, coated with a bright orange or scarlet aril. It is sometimes planted as an ornamental climber because of its showy fruit. The seeds are said to possess narcotic and stimulating qualities, while the bark is purgative and emetic. The scarlet-coated seeds of *C. paniculatus*, a common Brazilian species, yield an oil which is sometimes used for burning in lamps, and is in repute among native doctors. The seeds have a hot biting taste owing to a resinous matter contained in them. The plants comprised in this genus, commonly called Staff-trees, are found in the temperate regions of tropical countries, and appear in greatest number in the Himalayas. [A. A. B.]

**CELERIAC.** A turnip-rooted variety of the garden Celery.

**CELERY.** *Aptium graveolens*.

**CELLA.** A name sometimes given to a form of the perithecium among fungals.

**CELLS, CELLULES.** Cavities in the interior of a plant. The cells of tissue are those which form the interior of the elementary vesicles. Cells of the stem, air-cells, &c., are spaces organically formed by a peculiar building up of tissue, for various vital purposes.

**CELLULAR SYSTEM.** That part of the plant which consists of cells or elementary vesicles.

**CELLULARES.** A name given to Cryptogams, from a notion that they consist

entirely of cells. A more accurate acquaintance, however, with their anatomy has shown that vascular tissue exists in many of the higher forms, and that even in *Fungi* there are genera which possess true spiral vessels, while in one or two higher *Algae* the stem contains vascular threads, while the contents of the cells or endochrome are sometimes disposed in one or more spiral bands. In both, the cell-walls themselves have occasionally a spiral structure. *Podaxon* amongst *Fungi*, and *Conferva Melagontium* amongst *Algae*, afford excellent examples. [M. J. B.]

**CELLULOSE.** The primitive membrane, free from all deposits of sedimentary or other matter. Its composition, according to the latest analysis, is O 34 H 20 O 10.

**CELOSIA.** A genus of *Amaranthada*, consisting, with a few exceptions, of tropical annual plants, closely allied in their structure to *Amaranthus*, with which they agree in having the flowers three-bracted, a perianth of five-coloured scarious pieces, two-celled anthers, and a utricular seed-vessel splitting horizontally round when ripe; but differ in their five stamens being united at the base into a cup, in having a more or less elongated style, and in the utricle containing several seeds, instead of but one only. It is important to remark that the form of the *C. cristata* or Cockscomb usually found in cultivation, conveys a very incorrect idea of the inflorescence of this genus, the broad flattened stem with its terminal crest being a monstrosity, resulting from the lateral adhesion of the stems and branches by a process termed by botanists fasciation. In its normal phase the *C. cristata* is of erect habit, growing one to two feet high, with roundish striated stems pyramidal branched nearly to the base, alternate leaves of a lanceolate or ovate-lanceolate form, and flowers in either loose pyramidal panicles or compact spikes. In the beautiful, but now little known *C. aurea* of gardens, which is regarded by botanists as but a form of *cristata*, only a few of the flowers at the base of the panicle are perfect, those of the summit being abortive, and putting on the appearance of glossy yellow spirally-twisted scales, which gives the inflorescence a tassel-like form. There is a red-flowered variety of taller growth, with the blossoms in compact conical spikes. There are several other species agreeing with these in habit, but they are less ornamental, and possess little general interest. The flowers of the Cockscomb are reputed to be astringent, and are employed in India in diarrhoea and other maladies. [W. T.]

**CELSIA.** A small genus of *Linariads* distinguished by a wheel-shaped five-lobed corolla, and didynamous bearded stamens. It is closely allied to *Verbascum*, which differs from it chiefly in having five perfect stamens. The species are annual or biennial plants, in the latter case sometimes of shrubby habit, with entire or

pinnatifid foliage, and spikes of bright yellow mullein-like flowers. The biennial, *C. cretica*, found both in Candia and Northern Africa, is at the same time the best known and by far the showiest of the species. As cultivated in gardens, it attains a height of four or five feet, having the root-leaves of a lyrate form and the upper ones oblong, with a long terminal spike of large yellow blossoms, each of which arises from the axil of a small leaf or bract. The corollas have two brownish spots on the upper side near the centre, the two shortest stamens have their filaments bearded, and the segments of the calyx are sharply serrated. This plant affords a good example of what is termed by botanists a declinate style, this organ, as well as the two longer stamens, being very much bent upwards. *C. Arcturus*, a dwarf half-shrubby species, is sometimes met with in cottage-windows, and has, like the preceding, spikes of yellow flowers, but the calyx segments are all entire, and the filaments all bearded. [W. T.]

**CELTIS.** Nettle-tree. Handsome much-branched deciduous trees belonging to the *Ulmaceae*, distinguished at once from the true elms by their bearing instead of a membranous fruit a hard fleshy drupe, which is edible, and, though small, is remarkably sweet and said to be very wholesome. Several species have been introduced into Great Britain. The European Nettle-tree, *C. australis*, is a tree from thirty to forty feet in height, with a straight trunk and a branched head. The branches are long, slender and flexible, with a grey bark spotted with white, and covered with a slight down at the extremities. The bark of the trunk is rich brown. The leaves are dark green, marked strongly with the nerves on the lower side, and, when young, covered with a yellowish down. They are oval-lanceolate, terminating in a point at the summit, and at the base having one side prolonged down the petiole. The flowers are small greenish and inconspicuous, and are produced at the same time as the leaves. The fruit, which, when ripe, is blackish and resembles a very small withered wild cherry, is said not to become edible until the first frosts, and it hangs on until the following spring. It is remarkably sweet, and is supposed to have been the Lotus of the ancients, the food of the Lotophagi, which Herodotus, Dioscorides, and Theophrastus describe as sweet, pleasant, and wholesome, and which Homer says was so delicious as to make those who ate it forget their native country. The berries are still eaten in Spain, and Dr. Walsh says that the modern Greeks are very fond of them. According to Dr. Sibthorpe, they are called in modern Greece Honey-berries. The tree grows rapidly, more especially when once established and afterwards cut down, sometimes producing shoots in the climate of London, six feet or eight feet in length. *C. australis* is found on both the shores of the Mediterranean, throughout the whole of the south

of France, Italy, and Spain. It is peculiarly abundant in Provence; and there is a celebrated tree at Aix, under which it is said that the ancient sovereigns of Prussia delivered their edicts to the people. It is much used in the south of Italy and the south of France for planting squares and public walks, when it is frequently found from forty to fifty feet high, with a trunk from one and a half to three feet in circumference. The wood is extremely compact, ranking between that of the live-oak and box for hardness and density. The wood of the branches is elastic and supple. Its compactness renders it susceptible of a high polish, and when it is cut obliquely across the fibres it very much resembles satin wood. It is used for furniture and carving, and the branches are extensively employed in making hay-forks, coach-whips, ramrods, and walking-sticks (London). The North American Nettle-tree, *C. occidentalis*, differs from the European species in having longer leaves, which are of a lighter green, and in having the wood of a lighter colour in winter. The American Hackberry, *C. crassifolia*, is a very distinct species, and one of the finest trees which compose the dusky forests of the Ohio. The leaves are larger, more acuminate, of a thick texture with a rough surface. The fruit is round, and about the size of a pea. The Hackberry is found in the greatest abundance in the western states of America. The timber is of little value. *C. orientalis* and *C. aculeata* are low-spreading trees of inferior interest. French, *Micocoulier*; German, *Lotusbaum*. [C. A. J.]

**CENARRHENES.** A genus of *Proteeaceae*, found in Tasmania. Its flowers, which are apetalous, have four sepals with the points attenuated; four stamens with free filaments, inserted at the base of the sepals; and a filiform style with a simple stigma. These flowers are borne on spikes, rather shorter than the leaves. The fruit is a single-seeded berry. *C. nitida*, the only species, is a small tree about twenty-five feet in height, with shining coriaceous spatulate leaves, attenuated at the base, and remotely dentate, with a grooved petiole; they are from four to six inches in length and about one inch in width. [R. H.]

**CENCHRUS.** A genus of Grasses belonging to the tribe *Panicæe*, and scarcely differing from *Pennisetum*, except in the involucreal scales being more hardened, broader, and more or less connate at the base. Steudel describes thirty species, which are chiefly inhabitants of rather warm and dry countries, consequently they require the protection of a conservatory when cultivated in Britain. [D. M.]

**CENLIA.** A genus of the Composite order, having the flowers at the circumference of the heads either strap-shaped or with two lips; those in the centre tubular and four-toothed; the receptacle or part supporting the flowers inflated or hollow; and the fruit two-ribbed, without any crown-like appendage. The name of the genus is from the

Greek word signifying hollow or void, in allusion to the hollow receptacle. The species are natives of the Cape of Good Hope, and have alternate leaves, which are twice pinnate, the divisions being long and narrow. *C. turbinate* has been long known, having been introduced about the beginning of the last century. [G. D.]

**CENOBIUM**. — **CENOBIONAR**, **CENOBIONEUS**. — Fruits as those of labiates, borageworts, &c., which consist of several distinct lobes, not terminated by a style or stigma.

**CENOLOPHIUM**. A genus of *Umbelliferae*, nearly related to *Cnidium*, but differing in the mature seeds being enclosed in a loose pericarp, as well as in the ribs of the carpels being hollowed interiorly. *C. Fischeri*, the only species, is a tall smooth perennial weed, common throughout Russia, and sometimes cultivated in botanic gardens. It has many times ternate leaves, the segments narrow, lance-shaped, and nearly an inch in length; small white hemlock-like flowers, disposed in many-rayed umbels, with a general involucre of one bract, and numerous narrow bracts to the partial involucre; ovate-oblong nearly cylindrical fruits, each carpel having five sharp ribs, with an oil tube in each furrow, and two on the inner face. [A. A. B.]

**CENTAUREA**. An extensive and varied genus of Compositae, comprising both annual and perennial herbaceous or half-shrubby plants, some of them common weeds, e.g., *C. nigra*, the Knapweed of our pastures, while a certain number are esteemed border flowers. They are distinguished by a globose or ovate involucre of many imbricated scales or leaflets which are either fringed at the tip or furnished with appendages varying in form and character; by a bristly receptacle; by the florets being all tubular, the outer row usually much the larger, spreading and sterile; and by a compressed fruit, with or without pappus of simple bristles, and a lateral depression or hilum near the base. The species present great diversity of habit and foliage, some being of prostrate growth, others quite erect; while the foliage varies from entire to pinnatifid or bipinnatifid, and the flowers from white to blue, yellow, and purple.

Of the perennial species, one of the most common in gardens is *C. montana*, which grows one and a half foot high, and bears entire lanceolate downy leaves, and large capitules, the outer florets of which are pale violet blue, and the central ones deep purple. *C. macrocephala*, an erect growing species, of stiff habit, with entire leaves, stalked at the root but decurrent on the stem, has large solitary flower-heads of a fine yellow colour. In *C. dealbata*, with reddish purple flowers, the twice-pinnatifid foliage is whitened on the under side, a circumstance to which the name is due. *C. candidissima*, a native of the Levant, has the lyrate pinnatifid leaves clothed on both surfaces with a white silky tomentum, which gives it a striking aspect; and *C. Ragusina*, a Dalmatian species, has similar foliage: both these latter have yellow flower-heads.

Of the annual species one of the most remarkable is *C. americanus* or *Plectrocephalus americanus* of some authors, which has a stout erect stem four to five feet or more high, oblong lance-shaped leaves, and very large capitules of a lilac-purple tint. *C. depressa* is a pretty dwarf plant from the Caucasus, of somewhat procumbent habit, with entire lanceolate leaves, and flowers of a fine blue. Better known than any of the preceding is the common Corn Blue-bottle, *C. Cyanus*, an indigenous species of tall slender growth, the foliage greyish, and the flowers, in their wild state mostly of a light blue colour, but in gardens found varying from white to every shade of blue and purple. [W. T.]

**CENTAUREA DU NIL**. (Fr.) *Centaurea Crocodilium*. — **ODORANTE**. *Ambrosia odorata*. — **PETITE**. *Erythraea Centaureium*.

**CENTAURELLA**. A North American genus of herbaceous plants, belonging to the *Gentianaceae*, and also called *Bartonia*. It has thread like stems, little awl-shaped greenish scales in place of leaves, and smaller terminal four-parted funnel-shaped flowers, and a one-celled ovary, surmounted by a two-lobed stigma. [M. T. M.]

**CENTAURIDIUM**. A genus of *Compositae*. The only species, *C. Drummondii*, a Texan plant, has great resemblance to some of the knapweeds, but belongs to a different section of the family. The plant is biennial, a foot and a half high, much branched, with linear smooth jointed leaves, and single terminal yellow flower-heads. The ray-florets are strap-shaped and female; those of the disc tubular and perfect. [A. A. B.]

**CENTAURY**. *Erythraea Centaureium*. — **AMERICAN**. *Sabbatia*.

**CENTENILLE**. (Fr.) *Centunculus*.

**CENTINODE**. (Fr.) *Polygonum aviculare*.

**CENTRADENIA**. A genus of *Melastomataceae*, containing under-shrubs from Mexico and Central America, with four-sided branches, and opposite leaves (generally unequal in size and unequal-sided), which are ovate or lanceolate, entire, membranous, and three-nerved. The racemes are few-flowered, axillary; the flowers pink or white. Calyx tube four-sided, its limb four-parted; petals four; stamens eight; the two larger anthers spurred, the others with a glandular appendage to the connective; ovary free, four-celled, with a ring of hairs at the top. [J. T. S.]

**CENTRANTHERA**. A small genus of *Scrophulariaceae*, natives of tropical Asia and Australia. They are scabrous herbaceous plants, with generally opposite leaves, and almost sessile axillary flowers. The calyx is compressed, and split down the inner margin, entire or two to five-

toothed. The corolla tube is curved and dilated upwards; its limb has five broad lobes, the two upper being innermost in the bud. There are two pairs of included stamens, having transverse two-celled anthers, with mucronate cells. The capsule is obtuse. [W. C.]

**CENTRANTHUS.** A small genus of Valerian-worts, consisting of smooth annual or perennial European plants, with mostly entire opposite leaves, and small red or white flowers in terminal corymbose panicles, the flowers arranged unilaterally along the branches of the panicle. A slender tubular spurred corolla with a five-lobed limb, one of the lobes standing apart from the rest; a single stamen; a superior calyx of feathery pappus-like appendages rolled inwards before the corolla falls, and only expanded as the fruit matures; and a one-celled, one-seeded fruit are the principal features of this genus. It differs from *Valeriana*, in having a spurred corolla and but one stamen. The pappose calyx is a pretty object under a lens. The Red Valerian, *C. ruber*, formerly known as *Valeriana rubra*, offers a good example of the genus. It is said to be eaten as a salad in Southern Italy, and its sweet-scented roots probably partake in some degree of the antispasmodic and tonic properties occurring in the true valerians. *C. macrostemon* is a very pretty annual species from Spain, with smooth hollow stem, broadly ovate sessile leaves, entire, or pinnatifid, and very large corymbs of rose-coloured flowers. [W. T.]

**CENTRIFUGAL.** A term applied to those kinds of inflorescence which, like the cyme, flower first at the point or centre, and last at the base or circumference.

**CENTRIPETAL.** A term applied to those kinds of inflorescence which, like the spike or capitulum, flower first at the base or circumference, and last at the point or centre.

**CENTROCARPEA.** A group of the Composite family, differing in no way from *Rudbeckia*. The species referred to it are N. American perennial herbs very frequently met with in gardens. Their leaves are alternate, entire or lobed, and generally scabrous. The flower-heads are large and yellow, terminating the stem or branches. In *C. grandiflora* (otherwise *Rudbeckia grandiflora*), the flower-heads are sometimes more than six inches in diameter, and much like those of the sunflower, but smaller. [A. A. B.]

**CENTROCOLINIUM.** A genus of the Composite family, belonging to that section of the order which has two-lipped corollas. The four known species are herbs or small shrubs found in the Peruvian Andes at an elevation of 6,000 to 8,000 feet. Their leaves are alternate, stalked, toothed or entire, and covered beneath, as well as the stems, with a white tomentum. The purple flower-heads are axillary and single, on long stalks, and about an inch in diame-

ter; the ray-florets few and female, those of the disc numerous, and containing both stamens and pistil. The achenes are five-angled, crowned with a pappus of numerous unequal rough hairs, and seated on a flat receptacle furnished with short bristles. *C. adpressum* and *C. reflexum* have been in cultivation, but their rose-coloured flowers, which smell of Hawthorn, are very sparingly produced. [A. A. B.]

**CENTROLEPIS.** A genus of *Desvauzias*, containing a few small tufted sedge-like herbs from Australia and Tasmania. Leaves setaceous, all radical; scapes short, terminated by a simple spike contained in a spathe formed by two slightly unequal bracts (glumes of some authors); glumes (pales of those who consider the spathe-bracts as glumes) two, membranous, stamens one; ovaries two to twelve, becoming utricles in fruit. [J. T. S.]

**CENTROLOBIUM.** A genus of Leguminous trees found in Brazil, Guiana, and Venezuela. Their leaves are a foot or more in length, and unequally pinnate, the leaflets three to four inches in length, and, as well as all the young parts, clad with a rusty pubescence. The flowers are disposed in terminal panicles. The pod is the most remarkable part of the plant; it is like the fruit of the common Maple (*Acer*) in form, and about nine inches in length, the lower or seed-bearing portion globular, and clad with long straight prickles, the upper or winged portion thin, papery in texture, about two and a half inches in breadth, and bearing on its back near the base a long straight spurred spine, which is the hardened style. *C. parvifolius* furnishes one of the most esteemed timbers of the Orinoco; its colour is bright orange when fresh, but it fades to a brown after exposure; it is very strong, dense and durable. The name of the genus is derived from the spur-like hardened style which remains on the pod. [A. A. B.]

**CENTRON, or CENTRUM.** In Greek compounds = calcar, a spur.

**CENTROPAPPUS.** A genus of the Composite family, found in Tasmania, nearly allied to *Senecio*, and differing chiefly in habit. The only known species, *C. Brunonis*, is found about the upper limits of the forest on Mount Wellington, at an elevation of 3,000 to 4,000 feet. It is a smooth shrub, seven to ten feet high. The leaves are sessile, gathered together towards the ends of the branches, three to four inches long, and one-quarter of an inch broad. The flower-heads are in terminal corymbs, and in form and appearance bear great resemblance to those of the common yellow ragwort. [A. A. B.]

**CENTROPETALUM distichum** and *C. Waresowethii* are two small epiphytal Orchids from the mountains of tropical America, with fleshy distichous leaves, and brownish solitary flowers, with a broad lip adherent to a hooded column. The pollen-masses are four, free, attached in pairs to two

filiform curved caudicles which adhere to a common gland.

**CENTROPOGON.** A genus of *Lobeliaceae*, consisting of undershrubs with irregular flowers on long axillary stalks. The five stamens are united into a tube, and spring from between the corolla, and a ring-like fleshy five-lobed disc, surrounding the inferior two-celled ovary. The two lower anthers are terminated by an ovate triangular cartilaginous point. The plants are natives of tropical America. [M. T. M.]

**CENTROSEMA.** A genus of prostrate or twining perennial plants belonging to the *Leguminosae*, and distinguished from its nearest allies by its having on the back and near the base of the standard a short spur, from which circumstance the genus receives its name. The species are almost entirely American, and the greater number are found in Brazil. The leaves are made up of three leaflets, rarely of five or seven, the leaflets opposite and the terminal one rather distant; in two species they are digitately arranged and from three to five in number, while in a few others but one leaflet is present. The large and elegant pea-like flowers are single or in axillary racemes, and white violet rose or blue in colour. The pods are very narrow, compressed, thickened at both sides, and terminating in a long point; in some of the species they are eight inches long. The leaves of *C. macrocarpum* are eaten in Guiana. *C. virginianum* is found in Brazil and West Africa, as well as in the United States. Upwards of twenty species are known. [A. A. B.]

**CENTROSIS.** *Corymbis.*

**CENTROSOLENIA.** A genus of *Gesneraceae* from British Guiana, founded on a single plant, which has a short creeping stem, subcordate petiolate leaves, and solitary axillary peduncles, sometimes bearing many pedicels. The calyx is five-parted with serrate segments; the tube of the corolla has a spur at its base, and the limb is slightly expanded into five small broad lobes. The four included didynamous stamens, with the rudimentary fifth, are inserted in the base of the tube. The ovary is oblong-conical and hairy. This genus is a dentally allied to *Nematanthus*, but the spur of the flower, coupled with the habit and the toothed segments of the calyx, distinguish it. [W. O.]

**CENTROSPERMUM.** The name sometimes given to an annual cornfield weed of Spain and Algeria, very near to the genus *Chrysanthemum*, and very like our own corn-marigold, *Chrysanthemum segetum*. The schemes in the last-named plant are naked at top, but in this, *C. chrysanthemum* (Ch. viscosum), those of the ray-florets have a pappus of three, and those of the disc of one awn, while the stems are smooth and not alamy. [A. A. B.]

**CENTROSTEMMA.** A genus of *Asclepias*, containing five species, natives of

the Indian Archipelago, the Moluccas, and the Philippine Islands. They are twining shrubs, with opposite coriaceous leaves, and umbels on interpetiolar and terminal peduncles, composed of many large yellowish flowers. The calyx is five-parted. The limb of the corolla is deeply five-cleft and reflexed; a hairy ring exists in the throat of the corolla around the base of the gynostegium, which is exerted. The staminal corona consists of five fleshy leaves inserted on the summit of the gynostegium and surpassing the stigma. The anthers are surrounded by a spreading membrane which attaches them to the stigma; the pollen masses being oblong, with a pellucid interior margin, and attached by short processes. The pentagonal stigma is lengthened out into a cone. The foliicles are solitary, long and cylindrical, and contain numerous comose seeds. The hairy ring in the throat of the corolla separates this genus from *Hoya*, to which otherwise it is very nearly related. *C. multiflorum* is a well-known handsome hothouse shrub, often called *Cyrtoceras reflexum*. [W. O.]

**CENTUNCULUS.** Bastard Pimpernel. A minute herbaceous plant belonging to the *Primulaceae*, and closely allied to *Anagallis*, from which it may at once be distinguished by its four-parted flowers and four stamens, which are glabrous. The whole plant consists of a small fibrous root; a simple or slightly-branched stem, which rarely exceeds an inch and a half in height; from a dozen to twenty, or less, ovate-pointed sessile leaves; and a few solitary sessile flowers of a pinkish hue and of very short duration. The seed-vessels resemble those of pimpernel, for a starved specimen of which the plant might be mistaken. It grows in many parts of Great Britain in sandy or gravelly places, especially where water has stood during the winter, and not unfrequently in company with another minute plant, *Radiola Millegiana*. French, *Centenille basse*; German, *Centunkel*. [O. A. J.]

**CEPHAELIS.** The plant producing the true Ipecacuanha belongs to this genus of *Cinchonaceae*, which is characterised by its flowers being collected together in heads surrounded by a leafy involucre; the limb of the calyx very small and five-toothed; the corolla funnel-shaped with five small lobes; the anthers inclosed within the corolla; and the fruit succulent with two compartments, each containing a single seed, striated on the outer side. The Ipecacuanha plant is a native of Brazil. Its root, the part used in medicine, is flexuose but little branched, and the rind is marked by a number of circular projecting knots or rings which are very characteristic. The stem is creeping and herbaceous, with oblong obovate leaves and drooping heads of flowers. The emetic properties of the root are due to a chemical principle called *emetin*.

Ipecacuanha is largely employed in medicine as a safe emetic, and in smaller

quantities it acts on the skin, but especially on the bronchial passages. Some persons are so susceptible to the influence of this drug that they cannot remain in a room where there is *Ipecacuanha* without severe suffering. It is likewise highly esteemed in dysentery, though not so much so now as formerly. Louis XIV. paid 1000 Louis d'or to a physician named Helvetius for the purchase of a remedy for dysentery, under which the Dauphin was then suffering. This remedy was *Ipecacuanha*. Helvetius derived his knowledge of it from a merchant, who from gratitude for attention paid him during illness, by Helvetius, gave the latter some of the root as a remedy for dysentery. [M. T. M.]

**CEPHALANDRA.** A diaceous climbing Cucurbitaceous plant, native of the Cape of Good Hope, with thickened branches, simple tendrils, and large orange-yellow flowers with a five-toothed calyx. The five stamens grow in three parcels, inserted into the base of the corolla, and are adherent at the top into a globose head bearing the anthers—hence the name of the genus. The fruit is of the size of a pigeon's egg, and of a purple colour. [M. T. M.]

**CEPHALANTHERA.** A genus of Orchids cut off by Richard from *Epipactis*, which the species entirely resemble in their tough fibrous roots and broad ribbed leaves not only clothing the whole stem, but passing gradually into bracts. It differs from *Epipactis* in its anthers being terminal, as in *Arethusa*, not dorsal. The species have nearly regular white or red half-closed flowers with a saccate hypochil, and do not occur in the New World or the southern hemisphere. In the Old they are found from Western Europe to the extreme East of Asia, in the Japanese Archipelago. *C. pallens*, *ensifolia*, and *rubra* are wild in woods in this country.

**CEPHALANTHIUM.** The capitulum or flower-head of composites.

**CEPHALANTHUS.** A name expressive of the aggregation of the flowers into heads, and applied to a genus of Cinchonaceous plants called in North America Button-wood. The calyx is tubular with an angular four-toothed limb; the corolla tubular, with a four-toothed limb; the stamens four in number, scarcely protruding from the corolla; the style protruded for a considerable distance from the throat of the corolla; and the stigma capitate. The fruit is inversely pyramidal in shape, crowned by the limb of the calyx, two to four-celled, each cell or compartment containing one seed, or sometimes two of the seeds are absent. The seeds are terminated by a small thickened knob at one end. *C. occidentalis* is a bushy shrub with leaves opposite, or sometimes three in a whorl, and yellowish white flowers in round heads of the size of a marble. [M. T. M.]

**CEPHALARIA.** A genus belonging to the Teaselworts, characterised by having

the leaves, which surround the heads of flowers, shorter than the appendages which are attached to the surface supporting the flowers. The covering, technically called involucre, which surrounds each flower, is four-sided, with eight grooves, and four to eight teeth at the margin. The name of the genus is derived from the Greek word signifying a 'head,' indicating the form assumed by the groups of flowers. There are about twenty species known, some of which are natives of Middle Europe, others occur in N. Asia and at the Cape; they are mostly perennial herbs, a few being annual, with opposite leaves, which are either toothed or deeply divided; the flowers white, yellow, or lilac. [G. D.]

**CEPHALELYNA.** A section of *Evelyna*.

**CEPHALUM.** A peculiar woolly enlargement of the apex of the stem of *Melocactus*, among whose hairs the flowers appear.

**CEPHALODIUM.** A knob-like shield, such as occurs in the genus *Scyphophorus*. Also the capitulum of composites.

**CEPHALOMANES.** A name under which it has been attempted to separate a few species of *Trichomanes*, typified by *T. javanicum*. It is not generally adopted.

**CEPHALOPHORUM.** A term employed among fungals, sometimes to denote their receptacle, sometimes their stipe.

**CEPHALOTACEÆ.** The Australian Pitcher-plant, *Cephalotus follicularis*, a curious herb, with radical leaves mingled with pitchers, is a plant of very doubtful affinity. It has been considered provisionally as a distinct family, bearing the name of *Cephalotaceæ*. It has been compared with *Rosaceæ*, *Crassulaceæ*, and *Ranunculaceæ*; but according to the latest authorities (Bentham and Hooker) it is now classed with the *Saxifragaceæ*.

**CEPHALOTAXUS.** A genus of *Conifera* of the tribe or family of *Taxaceæ*, nearly allied to the yew (*Taxus*) in general habit, foliage, and essential characters; but the male flowers are in small heads, consisting of several closely-clustered catkins, and the fleshy disk, instead of forming an open cup round the base of the seed, completely closes over it into an entire pericarp, two or three of these fruits being collected into a drupe-like head. There are four or five species known, all from Japan or North China, one of which, *C. Fortunei*, is now frequently planted in our collections of conifers.

**CEPHALOTUS.** A genus of very singular dwarf Pitcher-plants. *C. follicularis*, the only species, is a native of swampy places in King George's Sound, and may frequently be met with in our green-house. It has a short or contracted stem, with spoon-shaped stalked leaves, among which are mingled small pitcher-like bodies, placed on short stout stalks, and closed at the top with lids like the true pitcher-plants (*Nepenthes*). These pitchers are of a green

colour, spotted with purple or brown, and provided with hairs; the mouth furnished with a thickened and regularly notched rim. The flowers are borne on a long spike, and have a coloured six-parted calyx, without a corolla; twelve stamens, six longer than the rest, inserted into a disc, the anthers provided with a large connective. There are six distinct carpels, each bearing a single seed. Dr. Hooker in a valuable paper on *Nepenthes* in the *Transactions of the Linnean Society*, says,

*Cephalotus follicularis*.

that there are no intermediate stages between the ordinary leaves and the pitchers of *Cephalotus*, but that the transition from one to the other is as sudden and abrupt as from the cotyledons to the pitchers in the seedling *Nepenthes* described by him. The writer of this notice, however, has on more than one occasion observed intermediate stages between the leaves and pitchers of this Australian Pitcher-plant, in the shape of leafstalks dilated and hollowed out at the point in the form of a horn, or of the mouth of a trumpet. [M. T. M.]

**CEPHALOXYS.** A section of the Rush genus (*Juncus*) containing such species as have the capsule perfectly three-celled, the valves breaking away from the partitions, which remain attached to the central columella. The *J. repens* of the southern states of North America is the type of this section. [J. T. S.]

**CEPHALUM.** In Greek compounds = the head, or terminal mass, or thickened end of anything.

**CERA DE PALMA.** The Peruvian name for the waxy resinous matter secreted by the wax-palm, *Ceroxylon andicola*.

**CERACEUS, CERREUS.** Having the consistence or appearance of wax.

**CERADIA.** A genus of the Composite family found on the south-west coast of Africa. The only known species, *C. ferocata*, is a shrub with fleshy horned and forking stems, bearing on their apex a number of bright green succulent veinless leaves,

which are entire and spatulate in form. From the axils of these the flower-heads proceed; they are solitary, of a pale yellow colour, and placed on stalks hardly as long as the leaves. The name *Ceradia* has allusion to the horned appearance of the branches. From the wounded stems of the plant exude small tears of a gum resin, which in burning has a smell resembling that of myrrh, and has been called African Bdellium. [A. A. B.]

**CERAISTE COMMUNE.** (Fr.) Any wild *Cerastium*.

**CERAMIAEAE.** A division of rose-spored *Algae* distinguished amongst those which have their spores collected without order within a hyaline sac (*Gongylosporema*), by the capsular fruit being either naked or surrounded by a whorl of threads. The external walls of the capsule vary in character, and are sometimes membranous (favella), as if formed of a transformed mother cell. The frond is either compound or simple and filamentous. [M. J. B.]

**CERAMIDIA.** A name given to the globose ovate or conical capsules of rose-spored *Algae*, mostly opening by a terminal pore, and quite distinct from the frond. They are, however, sometimes difficult to distinguish from coccidia. Examples are afforded by *Laurencia*. [M. J. B.]

**CERAMIUM.** A genus of articulated rose-spored *Algae* known at once by its central thread being covered at intervals with a layer of cells which give it a knotted appearance. Sometimes the sepals project so as to give the frond somewhat the appearance of the stem of *Equisetum*. The tetraspores are sunk in the frond. Capsular fruit, consisting of a hyaline cell containing many angular spores. Several species occur on the coast, one or two of which are amongst the most ordinary parasites, upon larger sea-weeds. *C. rubrum* is one of the sea-weeds most commonly collected by summer visitors to our coasts, abounding in company with the more delicate *C. pellucidum* in almost every little pool amongst the rocks. [M. J. B.]

The name is also a synonym of *Diagmoclisma*, a peculiar genus of South American Ferns. [T. M.]

**CERANAIBA.** The Brazilian name of Palm called *Copernicia cerifera*.

**CERASTIUM.** A rather extensive genus of *Coryophyllaceae*, containing small white-flowered plants, generally called Mouse-ear Chickweeds. Many of them are annuals, and are more or less hairy or glandular. They are distinguished from other genera of *Alsineae*, by their cylindrical capsule opening by twice as many teeth as there are styles, the latter being usually five. The petals are generally five. The number of sepals, petals, and stamens varies; it is generally five in the two former, and ten in the staminal whorl. Several species occur in Britain. *C. trigynum* is an Alpine decumbent plant with only three styles, while in

all the other British species there are five. *C. alpinum* and *C. latifolium* are Alpine plants with erect flowering stems, and petals much longer than the calyx; the former has soft, the latter short rigid pubescence. *C. arvensis* is a common English plant, somewhat resembling the last two, but with much narrower hairs, and the bracts and sepals membranous at the edges. The other species have the petals scarcely exceeding the calyx, and often shorter than it. [J. T. S.]

**CERASUS.** A genus of *Drupaceae*, frequently combined with *Prunus*, but distinguishable by having the following characters. The young leaves are folded in halves; the flowers are arranged in umbel-like tufts, appearing before the leaves or in terminal racemes which are produced with the leaves; the fruit is nearly globular in shape, destitute of the mealy bloom of the plum, or the down of the apricot, and having a roundish smooth stone. There are many species of this genus distributed over the temperate regions of both hemispheres; but as they are very subject to variations in habit and appearance, their discrimination is a matter of great difficulty. *C. Avium*, the Wild-cherry or Gean, is a native of Britain; it is a tree producing no suckers, its flower-buds are destitute of leafy scales, and the flesh of the fruit adheres to the stone, so as not to be readily separated from it. *C. vulgaris* is also a native of Britain; it is a shrubby plant, throwing up numerous suckers from its roots, the flower-buds have leafy scales, and the flesh of the fruit is readily separable from the stone. The wood of these trees is in great request in France, where mahogany is less common than with us; it is employed by cabinet-makers and musical-instrument makers. The bark also affords a yellow dye, while the leaves are said to be used to mix with tea. The fruits of *C. Avium* are employed in Switzerland and various parts of Germany in the distillation of a cheap spirit known as *Kirschwasser*. *Maraschino*, *ratafia* and other liqueurs are made in part from the fruits of this tree or some of its varieties. The stalks of the fruits are said to be employed in France as a diuretic. A kind of gum, analogous to tragacanth, exudes in great abundance from these and also from other species of this genus. It is employed by hat-makers and others. A double-flowered variety of *C. vulgaris* is in cultivation; its flowers are very showy and interesting botanically from the fact that the pistil is replaced by two small green leaves. *C. Padus*, the Bird-cherry, is also a native of the British Isles; in Scotland it is known as the Hagberry. It differs from the foregoing in the flowers being arranged in terminal clusters or racemes. The fruit is small, black, and nauseous to the taste. In the north of Europe it enters into the formation of a palatable liqueur; the juice is also expressed and drunk with milk, while the residue of the fruit is kneaded up into

cakes. *C. Mahaleb*, a native of the middle and south of Europe, is remarkable for the fragrance of its flowers, which, as well as the leaves are used by perfumers. A decoction of the leaves is also used in the manufacture of tobacco in France. The wood is prized by cabinet-makers, and in Austria the small branches are used for pipe-stems. *C. virginiana*, an American tree, frequently cultivated in this country, affords valuable wood for cabinet makers. Its bark is astringent and is esteemed for its febrifugal properties. From the fruits a liqueur is made, and when dried they are mixed with pemmican. *C. Capotim*, a native of Mexico, has also febrifugal properties. The rind of the root is used in cases of dysentery, and by tanners. The leaves and kernels of this, and indeed of most of the species, contain a greater or less proportion of prussic acid; thus the leaves of *C. virginiana* are dangerous on this account. *C. Copricida* derives its specific name from its fatal effects when eaten by goats in Nepal. It is this generally minute quantity of hydrocyanic or prussic acid that renders so many of these fruits useful for flavouring liqueurs; among others the kernels of *C. occidentalis* are used for flavouring noyeau.

The species heretofore mentioned have all deciduous leaves, but there are two well-known species, that have evergreen leaves. One is *C. lusitanica*, commonly called the Portugal laurel (though it has no botanical affinity with the true laurels: see *Laurus*), which is one of the commonest of evergreen shrubs, very hardy and very ornamental, especially when in flower. The leaves are dark green with reddish stalks; the flowers white, in clusters; and the fruits small, dark purple. These latter are much relished by birds. One of the largest bushes of this species is in the Duke of Marlborough's park at Blenheim. The other common evergreen species is *C. Lawrocerasus*, the Cherry-laurel, or Common laurel as it is usually called. This has widely lance-shaped remotely serrate leaves of a bright shining green colour above, dull on the lower surface. The leaves, bark, and fruit, as well as the oil obtained from them, are more or less poisonous. The vapour of the bruised leaves is sufficient to destroy small insects. Cherry-laurel water is a watery solution of the volatile oil of this plant; it contains prussic acid, and its effects, medicinal and poisonous, are similar to those of that acid. Sweetmeats, custards, &c., flavoured with the leaves of this plant have occasionally proved fatal; hence it is better to discard the use of these leaves altogether for these purposes, and to employ the leaves of the Sweet Bay, *Laurus nobilis*, instead, as these are equally agreeable in flavour, and harmless. The Cherry-laurel was introduced into this country from the Levant in the sixteenth century. [M.T.M.]

The numerous varieties of cultivated Cherries have in all probability originated from *C. Avium* and *C. vulgaris*. Those belonging to *C. Avium*, of which the Bigar-

reau and the Black Heart may be instanced as typical of the better kinds, have generally large pendent leaves, waved on the margin, with sharp prominent veins beneath, coarsely serrated, of thinner texture, and of a more yellowish-green colour than those of the *C. vulgaris*; buds pointed; flowers large, proceeding from wood of not less than two years old; petals loosely set; stamens slender, irregular in length, some being longer and others shorter than the style. From *C. vulgaris* are derived such varieties as the May Duke, Kentish, and Morello. The leaves are generally smaller than those of the preceding species, and have their margins plain, with the veins beneath as they approach the margin scarcely at all prominent, the parenchyma or fleshy substance of the leaves being much thicker than in the former; their colour is deep green; petioles comparatively short and thick, supporting the leaves nearly erect; petals roundish, forming a regular cup-shaped flower, with strong stamens, generally shorter than the style. Fruit round, roundish heart-shaped, or oblate, with aqueous flesh; colour red, dark red, or nearly black, none being white, nor white and red.

Both these species appear to be natives of Europe, although Pliny states that there were no Cherries in Italy before the victory obtained over Mithridates by Lucullus, who was, according to the above author, the first who brought them to Rome, about sixty-eight years before the Christian era. It is also stated by the same authority that, 'in less than 130 years after, other lands had Cherries, even as far as Britain beyond the ocean.' Pliny's statements, Professor Taglioli observes, gave rise to the tale, so generally received as a fact, that Cherries came originally from Cerasonte, now Zefano, and were therefore called Cerasus by the Latins. It may be here observed that nearly all the names of the Cherry in the south of Europe and Germanic languages are derived from the *Képasos* of the Greeks. Now, De Candolle says that the Cherry tree is decidedly wild in Europe, and especially in Greece, where it had existed from a very early period, for it is mentioned by Theophrastus B.C. 300, more than two centuries before its reputed first introduction to Rome by Lucullus from Cerasonte. Some authors are therefore of opinion that the name of that city had been derived from the tree, previously known as *Cerasus* in the south of Europe, and not that of the tree in question from the city. In the gardens of the latter, and in the surrounding country, Cherry-trees may have been so remarkably abundant as to occasion its being distinguished by their name.

When the Rev. Dr. Walsh visited Turkey in 1824, amongst other plants of which he gave an account (*Trans. Hort. Soc.* vi. 32), he mentions the abundance of Cherry-trees as follows: 'Præsum Cerasus, two varieties. The first of these varieties is a Cherry of enormous size, that grows along the northern coast of Asia Minor, from

whence the original Cherry was brought to Europe. It is cultivated in gardens always as a standard, and by a graft. The gardens consist wholly of Cherry-trees, and each garden occupies several acres of ground. You are permitted to enter these, and eat as much fruit as you please, without payment; but if you wish to take any with you, you pay about a halfpenny per pound. The second variety is an amber-coloured transparent Cherry of a delicious flavour. It grows in the woods in the interior of Asia Minor, particularly on the banks of the Sakari, the ancient Sangarius. The trees attain a gigantic size; they are ascended by perpendicular ladders suspended from the lowest branches. The trunk of one which I measured was five feet in circumference; and the height where the first branches issued forty feet; from the summit of the highest branch was from ninety to 100 feet; and this immense tree was loaded with fruit.'

From a country naturally so favourable to the growth of the Cherry, it is probable that Lucullus may have brought some varieties different from any known at Rome; but, being indigenous to Italy, Cherries must have been familiarly recognized by a name common to them in the south of Europe long before the Romans extended their conquests as far as Asia Minor. In consequence of Pliny's statement, the existence of the Cherry as a native of Britain has been questioned; but Mr. Knight was of opinion that Pliny 'must have meant a cultivated variety of the Cherry, of which the Romans had many in his time; for the small black Cherry which abounds in our woods has much too permanent habits to have been derived from any cultivated variety.' The species to which Mr. Knight alludes is the *C. Avium* or *C. sylvestris*, commonly to be met with in the woods of this and other countries of Europe. Some of its varieties are occasionally found almost equal in size and quality to the cultivated sorts. Among these may be mentioned the Couronne Cherry, so called from its being as black as a crow, which reproduces itself from seed, and is very abundant in several parts of England, and particularly in Hertfordshire. *C. vulgaris* does not appear to be in general so plentiful as *C. Avium*; yet there is a variety of it which grows wild, abundantly, by the sides of the Como Lake in Italy, and which proves to be a sort of Morello, but smaller and more round than the common. Varieties resembling it, and evidently belonging to the same species, have also been found wild in Britain.

With regard to the present race of cultivated Cherries, doubtless many of them were introduced from Holland and Belgium. Evelyn says, 'It was owing to the plain industry of one Richard Haines, a printer to King Henry VIII., that the fields and environs of about thirty towns, in Kent only, were planted with fruit trees from Flanders, to the unusual benefit and general improvement of that county to this day.' The Kentish, sometimes called

the Flemish, had probably been introduced at the above period, and likewise the Bigarreau; the former is the *Cerise de Montmorency*, and had most likely been obtained by the Dutch from France; but it would appear from Knoop that the Bigarreau tribe of Cherries had been introduced to the Continent from Spain; for, he says, in Germany and the Netherlands these are called Spanish Cherries (*Spannes Kersen*).

The cultivated varieties are now very numerous in this country. The following rank among the best: May Duke, Knight's Early Black, Elton, Bigarreau, Florence, Kentish and Morello. The last two are not properly dessert kinds, but are otherwise very useful. The Kentish is chiefly used for pies; its stalk is so strongly attached to the stone that the latter may be withdrawn from the fruit by it, so as to leave the cherry apparently whole, and in this state the fruit is laid on hair sieves and exposed to the sun, where it dries like a sultana raisin, becomes a delicious sweet-meat, and will keep thus for twelve months. The Morello is the sort chiefly employed for preserving in brandy.

Several highly-esteemed liqueurs are prepared from Cherries. The German Kirschwasser is made by distilling the fermented juice of the pulp with which the stones and kernels are ground and mixed. Maraschino, the most celebrated liqueur of Italy, is also obtained by the distillation of a small black Cherry, with which, while fermenting, honey, some cherry leaves, and the kernels of the fruit, are mixed. The celebrated Ratafia of Grenoble is prepared from pounded Cherries, to which brandy, sugar, and spices are added, the mixture being then placed in the sun or near a fire. The gum of the Cherry tree closely resembles gum Arabic in its nature and properties. The wood is hard and tough, and is used by the cabinet-makers. It has been occasionally employed for rifle stocks instead of walnut.

[R. T.]

**CERATANDRA.** Under this name are collected several species of terrestrial Orchids, inhabiting the Cape of Good Hope. They have grassy leaves, covering the scape, and closely packed green or yellow flowers, turning black in drying. The anther is a great inverted horseshoe-shaped body; the lip, which is heart-shaped or angular, and bears some kind of process in its middle, is attached to the face of the column by a narrow ungula. The species grow in sand, into which they introduce long succulent hairy fibres; they seem to be uncultivable.

**CERATIOLA.** A small heath-like evergreen shrub, belonging to the *Empetraceae*, among which it is distinguished by its two-leaved membranaceous calyx, with four scales at the base, two petals, and two stamens. *C. ericoides*, the only species, is an upright much-branched shrub, greatly resembling a heath, and varying from two to eight feet high; the branches are erect, somewhat whorled, and marked with the

in whorls of four, very narrow and spreading. Flowers brownish, and very small, solitary in the axils of the upper leaves. A native of South Carolina, on the Edisto River, where it covers a space 300 or 400 yards in width, and two or three miles long. [C. A. J.]

**CERATITIS.** A name applied by Link to the long ragged species of *Aspidium* which grow on the leaves of the mountain ash and whitethorn, sometimes attacking the fruit of the latter and distorting it. They are now placed in the genus *Ranunculus*, to which we shall have occasion to refer hereafter. [M. J. B.]

**CERATIUM.** A long slender horn-like one-celled superior fruit, which is usually called a capsula siliquiformis, as in *Epeyrum*.

This is also the generic name of a genus of Isarioid Fungi, consisting of short branched hollow threads which easily collapse, and bear abundant spores on spicules seated on the surface. *C. hydnoides* is not uncommon in this country, and occurs abundantly in Ceylon and elsewhere. [M. J. B.]

**CERATOCALYX.** A genus of *Orobanchaceae*, containing a single species, parasitic upon the roots of other plants, a native of mountains in Spain. It has a simple scaly stem, and solitary sessile flowers in the axils of the bracts, like *Orobancha*, from which it scarcely differs, except in the structure of the calyx, which is gamosepalous, with a campanulate tube lengthened out laterally into two acute narrow lobes, truncate before and behind, and exhibiting no traces of the union of the sepals. [W. C.]

**CERATOCAPNOS.** A genus of *Fumariaceae*, the four petals of which are spurred at the base and two-lobed at the apex; stamens six, united into two bundles; style simple, deciduous. Fruit either a one-seeded nut, marked with five ribs, and terminated by a long beak, or a lance-shaped pointed capsule, two-valved and two-seeded, the valves marked with five ribs. The plants are scrambling shrubs, natives of Syria and Algeria. [M. T. M.]

**CERATOCERPHALUS.** A small genus of *Ranunculaceae*, natives of Central and Southern Europe. They are small annuals covered with cottony hairs, having many-cleft radical leaves, and numerous short one-flowered scapes; calyx with five sepals; petals five, small, yellow; stamens five to fifteen; ovaries numerous. Achenes in an oblong spike on the receptacle; they have two protuberances and two empty cells at the base, and terminate in sword-shaped beaks, about half an inch long when mature. This beak which characterises the genus, is curved upwards in the commonest species, *C. falcatus*, but is nearly straight in *C. orthoceras*. [J. T. B.]

**CERATOCHILUS.** Under this name stand three very little known diminutive Orchids with simple stems, fleshy distichous leaves, and minute catkins.

live among mosses which partly conceal them. The supposed genus *Oma* is one of the species. The *Ceratocitus* of Lodiges' *Botanical Cabinet* is *Stanhopea*.

**CERATOCHELOA.** A genus of Grasses belonging to the *Poaceae*; only one species has been described, namely, *C. pendula*, which is *Bromus Schraderi*, a native of Carolina. [D. M.]

**CERATODACTYLIS.** A synonym of *Ilavea cordifolia*, a beautiful Mexican Fern, with alliguliform fertile planules. [T. M.]

**CERATOGONUM.** A genus of *Polygonaceae* founded on a plant cultivated in the Calcutta Botanic Garden. The leaves are stalked, ovate-triangular or hastate, with ochreate stipules, ciliated at the apex, and extra-axillary lax filiform flower-spikes. The flowers are monoeceously polygamous, the males with a five-parted coloured calyx, while that of the perfect flowers consists of six segments in two rows, the three inner ones petaloid, the three outer leathery, inserted into a tube; stamens eight; nut adhering to the tube of perianth. [J. T. S.]

**CERATONIA.** A genus of Leguminous plants remarkable on account of its flowers being destitute of a corolla, having only a small five-parted calyx, five stamens, and a pistil with a sessile stigma. The male and female organs are occasionally produced in distinct flowers on different trees.

*C. Siliqua*, the only species, is a native of the European, African, and Asiatic countries bordering on the Mediterranean, where it forms a small branching tree about thirty feet in height, having wood of a pretty pinkish hue. Its pinnate leaves are composed of two or three pairs of oval blunt-topped leaflets, of a leathery texture, and a shining dark-green colour. The flowers are in small red racemes; and are succeeded by flat pods, from six inches to a foot in length, an inch or rather more in width, and scarcely a quarter of an inch in thickness, of a shining dark purplish-brown colour; they do not split open like many other pods, and contain numerous small seeds arranged in a line along the centre of the pod, each seed being contained in a separate cell formed by the fleshy pulp of the pod. The tree is extensively cultivated in many of the above-mentioned countries, especially in such as suffer from periodical drought, its long roots penetrating to a great depth in search of water. It is called *Algaroba* by the Spaniards, and *Kharoub* by the Arabs, whence comes our English name Carob or Caroub, the pods being called carob-pods, or carob-beans, or sometimes sugar pods. These pods contain a large quantity of agreeably flavoured mucilaginous and saccharine matter, and are commonly employed in the south of Europe for feeding horses, mules, pigs, &c., and occasionally, in times of scarcity, for human food. During the last few years considerable quantities of them have been imported into this country and used for feeding

cattle; but although they form an agreeable article of food, they do not possess much real nutritive property, the saccharine matter belonging to the class of foods termed carbonaceous or heat-givers, the seeds alone possessing nitrogenous or flesh-forming materials, and these are so small and hard that they are apt to escape mastication. They form one of the ingredients in the much-vaunted cattle-foods at present so extensively advertised, the green tint of these foods arising from this admixture. Some years ago they were sold by chemists at a high price, and were used by singers who imagined that they softened and cleared the voice. By fermentation and distillation they yield a spirit which retains the agreeable flavour of the pod.

Besides the name of Carob-beans, these pods are also commonly called Locust-pods, or St. John's Bread, in consequence of its having once been supposed that they formed the food of St. John in the wilderness, but it is now more generally admitted that the locusts of St. John were the animals so called, and which are at the present day used as food in Eastern countries. There is more reason, however, for entertaining the belief that these pods were the husks mentioned in the parable of the prodigal son. The small seeds are said to have been the original carat weight used by jewellers. [A. S.]

**CERATOPETALUM.** A genus of Australian shrubs or small trees, belonging to *Rhamnaceae*. The leaves are opposite, ternate, with the leaflets coriaceous, serrated, the stipules somewhat leaf-like, caducous. The flowers are small yellow in terminal panicles; the calyx tube is adherent to the ovary, and the limb is five-parted; petals five, cut into a fringe of linear segments; stamens ten, the anthers beaked; capsule one-seeded, gaping at the apex, and crowned by the calyx limb. They have a gummy secretion. [J. T. S.]

**CERATOPHYLLUM, CERATOPHYLLACEÆ.** An aquatic floating herb, with numerous verticillate linear-filiform leaves several times forked; and minute sessile unisexual flowers of the most simple construction. There is no real perianth, but each flower is surrounded by a whorl of minute bracts; the males consist of twelve to twenty oblong sessile anthers; the females of a small ovary with a simple style, and containing a single pendulous ovule. The fruit is a small nut, smooth or more or less armed with prickly appendages, the seed has no albumen, and the embryo is remarkable for a highly developed placenta. The plant has some general resemblance to the aquatic *Halimolobos* or the *Callitriche*, but there is nothing in its nature to indicate any immediate affinity with the various families to which it has been appended, and it stands at present as an isolated genus or family. *C. demersum*, the only species known, is common in pools or slow streams over a great part of the world.

It varies much in the shape and excrecences of the fruit, and has been accordingly divided by some botanists into six or more supposed species, more generally considered as varieties.

#### CERATOPSIS. *Epipogon*.

**CERATOPTERIDINÆ.** One of the primary subdivisions or tribes of the podiaceous Ferns, distinguished by the broad incomplete or rudimentary condition of the ring of the sessile globose spore-cases, the latter containing few large spores, concentrically striated on their three faces. [T. M.]

**CERATOPTERIS.** A peculiar genus of tropical aquatic Ferns, constituting the group *Ceratopteridines*, or the *Parkeræ* of some authors. They have sometimes been associated with the *Pteridæ*, or even the *Polypodiæ*, but seem to be more correctly regarded as a distinct group, characterised by having the ring of the spore-cases very broad, incomplete, or merely rudimentary and obliquely vertical, the spore-cases being sessile, or nearly so, and the spores few, comparatively large, obtusely trigonal, each of the faces being beautifully marked with concentric lines. The only species, *C. thalictroides*, is found scattered through the tropical and sub-tropical regions of Asia, Africa, America, and Australasia, either floating or attached to the soil in shallow still or slightly moving waters. The fronds are much divided, membranaceous, and succulent in the fresh state: the sterile ones more foliaceous and less divided, with evident reticulated veins; the fertile ones taller and more erect, and divided into linear somewhat siliquose segments, everywhere scurfy beneath the recurved indusium-like margin, and with the veins distinctly anastomosing. Both forms of frond, especially the sterile ones, are proliferous, often freely so. The succulent foliage of this fern is boiled and eaten as a vegetable by the poorer classes in the Indian Archipelago. [T. M.]

**CERATOSTACHYS.** A genus now united with *Nyssa* (*Cornaceæ*), containing a tree from Japan, with oblong entire smooth leaves, glaucous beneath, and axillary solitary spikes of flowers, forming dense heads. [J. T. B.]

**CERATOSTEMMA.** A genus of Yuccinaceous plants, consisting of Peruvian shrubs, with superior five-toothed calyx; a tubular corolla with a five-toothed limb; ten stamens included within the corolla, the filaments united below into a cup, and the anthers opening by pores; and a five-lobed ovary with several seeds, ripening into a kind of berry surmounted by the limb of the calyx. [M. T. M.]

**CERATOSTYLIS.** A small and unimportant genus of terrestrial Orchids inhabiting tropical Asia. It contains two sections, one made up of species with long terete one-leaved simple stems with a dense cluster of minute flowers in

the axil; the other with a branched stem like that of caulescent *Maxillarias*. These last constitute the spurious genus *Trigonanthus*.

**CERATOTHECA.** A genus of *Scamææ*, containing a single species from tropical Africa. It is a herbaceous plant, with an erect tetragonous stem, opposite petiolate and dentate leaves, and single flowers on short axillary peduncles, with two glanduliferous bracteoles at their base. The persistent calyx is deeply divided into five acuminate lobes; the corolla tube is short and campanulate, and the limb bilabiate and five-cleft. There are four didynamous stamens, and no trace whatever of the fifth. The style is simple and deciduous, with a bilamellate stigma. The membranaceous truncate capsule has the corners of the apex produced into two or generally four horns. The free central placenta bears many flat obovate seeds. [W. C.]

**CERATOZAMIA.** The name of this genus of *Cycadaceæ* refers to its most prominent distinguishing feature: the presence of two horns on the scales of its xamia-like fruit. The stem is short and globular, giving off numerous pinnate leaves. The flowers are dioecious; the males in cones, whose scales are provided with two little teeth at the point, and with numerous anthers on their under surface; the females consisting of numerous scales with a thickened hexagonal disc-like top provided with two diverging horns, each scale concealing two seeds. The plants are natives of Mexico. [M. T. M.]

**CERBERA.** This name is intended to imply that the plants to which it belongs, are as dangerous as Cerberus; and some of them indeed are poisonous. Botanically, it is applied to a genus of *Apocynaceæ*, consisting of trees, natives of tropical Asia, with terminal flowers disposed in corymba. The corolla is funnel-shaped, with the limb divided into five oblique lobes, and the throat provided with five teeth. The stamens are five, included within the corolla, their anthers tipped with a distinct spine. The ovary is two-lobed, with two compartments, having two to four seeds in each. The stigma is discoid, with a wavy margin. The fruit consists of two separate drupes, one of which is usually abortive. The inner shell of the drupe is fibrous, partly divided, when ripe, into two divisions, and, when seen in the dried state, much resembling a ball of string. These plants possess a milky juice of a poisonous character, though some of the species are said to be destitute of the venomous qualities possessed by the rest. The seeds of *C. Asotus* are very poisonous, and the wood of this tree has an abominable odour. The seeds of *C. Manghas* are emetic and poisonous. *C. Odollam*, a Malabar tree, is cited by Lindley, as being innocuous, but this character applies probably to the fleshy drupe, the nut in the interior being narcotic and even poisonous. The bark is purgative: the unripe fruit, more-

CACTUS VEGETATION OF NEW MEXICO  
(After Mollhausen)

A *Cereus gy*

inches long, of a green colour and oval form, having a broad scar at the top caused by the flowers falling away; when ripe they burst into three or four pieces, which curve back so as to resemble a flower. Inside they contain numerous little black seeds imbedded in a crimson-coloured pulp which the Pinos and Papagos Indians make into an excellent preserve; and they also eat the ripe fruit as an article of food, gathering it by means of a forked stick tied to the end of a long pole.

*C. MacDonaldia* is one of the night-flowering kinds, and is of great beauty, its flowers when fully expanded being as much as fourteen inches in diameter, having numerous radiating red and bright orange sepals and delicately white petals. The stems are cylindrical, creeping, and branched, not much thicker than the little finger, and having here and there small swellings with a spine in the centre. It is a native of Honduras. The most common night-flowering kind is the *C. grandiflora*, a native of the West Indies. [A. S.]

**CERFEUIL.** (Fr.) *Scandix Cerefolium*. — **A' AIGUILLETES.** *Scandix Pecten-Veneris*. — **CULTIVE.** *Anthriscus Cerefolium*. — **DES FOUS.** *Anthriscus vulgaris*. — **MUSQUE.** *Myrrhis odorata*.

**CERINTHE.** A small genus of Borage-worts, consisting, with one exception, of annual plants, with oval glaucous stem-clasping leaves, and tubular flowers in one-sided drooping leafy racemes. The species are mostly European, and are more remarkable for their singularly glaucous aspect than for beauty. Two species, *C. major* and *C. minor*, have been long cultivated in gardens under the name of Honeywort, an appellation due to the abundance of honey secreted by their blossoms, which are much resorted to by bees. *C. major* grows about a foot high, with a branched stem, oval stem-clasping leaves, minutely toothed at the margin, set with rough white dots, and covered with a bluish-white bloom. The crook-like racemes of flowers have on each side a row of imbricated oval leaves, the purplish corolla being about an inch long, contracted at the mouth, with a narrow five-toothed spreading margin, and a fruit of two conical black nuts. *C. minor* has smaller yellow flowers, the segments of which are connivent and not reflexed. In *C. retorta* the tube of the corolla is curved, and the leaves are blotched with silvery-white. [W. T.]

**CERINUS.** The colour of yellow wax.

**CERIOPS.** Trees distinguished from the neighbouring genus *Rhizophora*, by their small five-parted flowers, the petals of which are hairy at the points. The ten stamens are placed in pairs before the petals. The lower part of the ovary has three compartments and six ovules, while the upper part is solid, and ends in a style which is longer than the stamens. Like the rest of the Mangrove family the seed has the curious habit of germinating and

protruding from the fruit while still attached to the bough. The trees are natives of the shores of tropical Asia and Australia. [M. T. M.]

**CERISSETTE.** (Fr.) *Solanum pseudo-Capsicum*.

**CERISIER À BOUQUETS.** (Fr.) *Cerasus vulgaris*. — **D'AMOUR.** *Solanum pseudo-Capsicum*. — **DE LA TOUSSAINT.** *Cerasus semperflorens*. — **NAIN.** *Lonicera tatarica*, and also *Cerasus Chamaecerasus*. — **PETIT DES HOTTENTOTS.** *Celastrus lucidus*.

**CERIUM, CERIO.** Same as *Caryopsis*.

**CERNUE.** (Fr.) *Agrostis stolonifera*.

**CERNUOUS.** Inclining a little from the perpendicular; generally applied to drooping flowers.

**CEROCHILUS.** *Rhamphidia*.

**CEROPEGIA.** A genus of *Asclepiadaceæ*, containing more than fifty species of perennial herbaceous plants or undershrubs, natives of India and Africa. They have a bulbous root, and short erect or slender twining stems, with opposite leaves and interpetiolar umbels of few or many flowers. The calyx is five-parted. The corolla tube is slender in the middle, expanding more or less below as well as above, where the limb divides into five generally slender portions, which being united at their points form a globose head. The staminal corona consists of five, ten, or fifteen ligulate lobes in one or two series. The gynostegium is included. The anthers have no membrane. The pollen masses are rounded, have a pellucid interior margin, and are connected by short processes. The slender follicles are cylindrical with comose seeds. Several species are employed for food; in some cases the whole plant is eaten as a salad, in others the fleshy leaves, stems and tubers, are used as pot vegetables. [W. C.]

**CEROPTERIS.** A name formerly proposed but not adopted for the species of *Gymnogramma*, which have the surface covered by a coloured powdery secretion, and which are familiarly known as Gold Ferns and Silver Ferns, from the colour of this substance which is of a waxy nature, whence the name. [T. M.]

**CEROXYLON.** This genus of Palms is by some botanists combined with the genus *Iriartea*, from which, however, it is distinguished by the spathe or bract which covers the young flower-spikes being entire (in *Iriartea* it is divided), by some of its flowers being perfect, while those of *Iriartea* are all imperfect, and also by a slight difference in the position of the embryo in the seed. Both calyx and corolla are three-parted, the calyx being very minute; the stamens are generally twelve in number, but occasionally vary from nine to fifteen; and the females have a three-celled ovary and three stigmas. The fruit is a small round berry containing

one seed. Three species of this genus are known, two of which are noble trees of great height.

*C. andicola*, the Wax Palm of New Grenada, was first made known and described by the celebrated travellers Humboldt and Bonpland, who found it growing in great abundance in very elevated regions on the chain of mountains separating the courses of the rivers Magdalena and Cauca, in New Grenada, extending almost as high as the lower limit of perpetual snow, which is a remarkable fact when it is remembered that the generality of the palm tribe luxuriate in tropical climates. It has a straight trunk of great height, and about a foot in diameter, cylindrical for the first half of its height, after which it swells out, but again contracts to its original dimension at the summit; but the most singular feature connected with the trunk is the circumstance of its being covered with a thin coating of a whitish waxy substance which gives it a curious marble-like appearance. It is surmounted by a tuft consisting of from six to eight

from it. The candles used by the inhabitants for offerings to the Saints and Virgin are, however, made without any such mixture; but on account of their resinous nature the priests will not allow them to be used for the high ceremonies of the Romish Church. The wood is very hard towards the exterior, and is commonly employed for building purposes; and the leaves are used for thatching. [A. S.]

**CERVANTESIA.** A genus belonging to the order of Sandalworts, characterised by the disk, or part intervening between stamens and pistil, being five-cleft, shorter than the flowers, and adherent to it below, the style or appendage on the seed-vessel thick and slightly notched at the end. The name was given in honour of Cervantes. The species are trees or shrubs, natives of Peru, having scattered entire simple leaves. The fruit of *C. tomentosa* is used as food in Peru. [G. D.]

**CERVINE.** Deep tawny, such as the dark part of a lion's hide.

**CESTREAU A' BAIRES NOIRES.** (Fr.) *Cestrum Parqui*.

**CESTRUM.** A genus of Solanaceous shrubs, of which several are in cultivation in this country, though of no great beauty. They have a funnel-shaped yellowish fragrant corolla concealing the stamens, whose anthers open longitudinally. The fruit is a dark-coloured berry, enclosed within the calyx, with two compartments (or from the union of the placentae and breaking down of the partition, one only) with few seeds, and a straight embryo. The plants are natives of Brazil. Some of them possess a bitter principle like quinine, while others are used as diuretics, and for other medicinal purposes. [M. T. M.]

**CETERACH.** A genus of polypodiaceous Ferns of the group *Asplenites*, distinguished by having distinct simple sori, reticulated veins of which the marginal veinlets are free, and fronds clothed thickly with scales, among which the sori are hidden. One species is a commonish native fern called Milkwort or Scale Fern, and another of twice the stature is found in the Canary Islands, both being alike coriaceous, and clothed on the under surface with a thick covering of imbricated tawny scales, by which peculiarity the British species may be readily known from all other native ferns. To this plant was formerly attributed a marvellous influence over the spleen, and Viruvius states that it had the effect of destroying that organ in certain Cretan swine which fed upon it. So Gerard writes:—'There be empiricks or blinde practitioners of this age who teach that with this herbe, not only the hardness and swelling of the spleen, but all infirmities of the liver, may be effectually, and in a very short time removed. But this is to be reckoned amongst the old wives' fables, and that also which Dioscorides telleth of touching the gathering of Spleenewort in the night, and other most vaine things

*Ceroxylon andicola.*

handsome pinnate leaves, each of which is about twenty feet long, and has a strong thick footstalk, the base of which spreads out and clasps round the trunk, leaving a circular scar when it falls away; the leaflets are densely covered on the under side with a beautiful silvery scurf, while the upper side is of a deep green colour. The waxy substance of the trunk forms an article of commerce amongst the inhabitants of New Grenada. It is obtained by cutting down the tree and scraping it with a blunt implement, each tree yielding about twenty-five pounds. According to the analysis of Vauquelin, it consists of two parts of resin and one of wax, and is therefore of too inflammable a nature to be used by itself; but by mixing it with one-third part of tallow, very good candles for ordinary purposes are manufactured

which are found here and there scattered in old books.' It is said, however, to be still usefully employed as a bait for rock-od fishing on the coast of Wales. The genus is a somewhat anomalous one as to classification, the Indusium, which is one of the characteristics of the *Asplenites*, being here either wholly wanting or merely rudimentary. The sori are nevertheless unilateral, and something like an indusium has been detected, so that it is now generally associated with the *Asplenites* as it was by Linnaeus. The name *Oeterach* has also been used by Presl to distinguish a section of *Gymnogramma*. [T. M.]

**OTETARIA.** A genus of lecidineous lichens distinguished by the fructification being fixed laterally to the borders of the thallus, and consequently margined by it. It is not, however, petitate. It deserves notice here as containing *O. islandica*, or the well-known Iceland Moss, which affords at once a nutritious article of food, and a doubtful medicine. Before using it requires to be steeped for several hours to get rid of a bitter principle. It is sometimes bottled to form a jelly, which is mixed with milk or wine; sometimes it is reduced to powder and used as an ingredient in cakes or bread. It is esteemed by many useful in pulmonary complaints or as a restorative, but after the bitter principle has been extracted it seems to possess no active qualities. [M. J. B.]

**CEVADILLA.** The seeds of *Asagraea officinalis*.

**CHA DE FRADE.** A Brazilian name for a decoction of *Casearia lingua*. — **DE PEDRESTE.** A Brazilian name for *Lantana pseudo-Thea*.

**CHABREÆA.** The generic name of plants belonging to the Composite order, having the flowers uniform, smooth, two-lipped, the lips bent down, the outer largest and three-toothed, the inner with two teeth; the fruit narrow below, covered with short projections, and crowned with feathery appendages. The name was given in honour of Chabrè, a botanist of Geneva. The species of this genus are natives of Chili and of the Straits of Magellan; they have alternate leaves, those below mostly twice pinnate; and the heads of flowers are purplish. Dr. Hooker, in the *Flora Antarctica*, alludes in these terms to *C. suaveolens*: 'The odour of this plant, which is a great ornament to the grassy hills of the Falkland Islands, is decidedly that of benzoin.' [G. D.]

**CHACA, or OBOCO.** *Sesctium edule*.

**CHÆNANTHE.** *Diadenum*.

**CHÆNESTHES.** A genus of trees or large shrubs, belonging to the Solanaceae family, and having long crimson or orange-coloured flowers of much beauty, like those of *Dunalia*, an allied genus; but the stamens, in the present instance, are destitute of the lateral appendages which characterise *Dunalia*. There is another

distinguishing feature in the peculiarity of the tubular calyx, which splits open by the growth of the fruit. The trees grow in the valleys of the Andes. [M. T. M.]

**CHÆNOSTOMA.** A considerable genus of herbs or undershrubs, belonging to *Scrophulariaceae*, natives of South Africa. They have opposite dentate rarely entire leaves, and axillary or racemose pedicellate flowers, which do not blacken in drying. The calyx is five-parted, the deciduous corolla is funnel-shaped, sometimes with a short tube, and its limb is five-cleft. There are four didynamous stamens the length of the corolla or slightly exserted. The style is simple, and the stigma subclavate. The capsule is membranaceous and two-celled. [W. G.]

**CHÆRADOPLECTRON.** *Glossula*.

**CHÆTA.** A bristle. The slender stalk of the spore-case of mosses; also called *Seta*.

**CHÆTACHINE.** A small spiny S. African genus, belonging to the *Ulmaceae*. It differs from the elm in not having winged fruits, and from *Sponia* or *Celtis* in its natural habit more than in anything else. The leaves are smooth or downy, oval or elliptical in form, with entire or toothed margins, and from one to two inches long; they are generally terminated by a bristle, and accompanied at the base of the stalks by two short spines. The flowers are small and green, male and female on the same plant; the males are numerous in the axils of the leaves, and have a five-parted calyx with five stamens opposite its divisions; the females are single in the axils of the leaves, with a similar but smaller calyx, enclosing a one-celled ovary, which is crowned with two reflexed stigmas. The fruit is a little oval nut, about the size of a pea, with one seed. In some works the name has been spelt *Chætachyne* and *Chætachne* by mistake. [A. A. B.]

**CHÆTOGASTRA.** A genus of *Melastomaceae*, natives of tropical America, allied to *Arthrostemma*, but with the parts of the flower in fives. Like that genus the present is an unnatural one, the species having only trifling technical characters in common. [J. T. S.]

**CHÆTOSTOMA.** A genus of small dry heath-like Brazilian shrubs, belonging to *Melastomaceae*. Stems leafless at the base; flowers solitary, rather small, purple with yellow anthers; parts of the flowers in fours or fives, the stamens being twice as many as the petals; capsule free, cylindrical, three-celled. [J. T. S.]

**CHÆTURUS.** A genus of Grasses belonging to the tribe *Agrostideae*. The only species described, *C. fasciculatus*, is a small annual grass, a native of Spain. [D. M.]

**CHAFF, CHAFFY.** The same as paleaceous.

**CHAFF-FLOWER.** *Alternanthera Achromatica*.

**CHAFF-SEED.** An American name for *Schoalbea*.

**CHAFF-WEED.** *Centunculus minimus*.

**CHAGAS DA MINDA.** A Portuguese name for *Chymocarpus*.

**CHAILLETIA.** A genus which gives its name to the family of *Chailletiaceae*. It is found more or less in most tropical countries, but represented in greatest numbers in Brazil. The species are small erect trees or shrubs, but sometimes (as in *C. pedunculata*, a Guiana species) extensive climbers, reaching the tops of the highest trees. The leaves are shortly-stalked, alternate, entire, and generally oval in form. The flowers are small white, often odoriferous and disposed in axillary-cymes and racemes; the calyx five-leaved; the corolla of five cleft petals; the stamens five; and the ovary two or three-celled, crowned with a like number of styles, and becoming when ripe a somewhat dry drupe, with one or two seeds. The only extra-tropical species is *C. cymosa*, which is a native of South Africa, and has oblong obtuse leaves; and the only species whose uses are recorded is *C. toxicaria*, a native of Sierra Leone, where the seeds of this plant are said to be used by the colonists for poisoning rats, and by them called *Ratahane*. Upwards of thirty species are known. [A. A. B.]

**CHAILLETIACEÆ.** A family of Dicotyledons, belonging to Lindley's Rhamnal alliance, differing from *Celastraceæ* in their usually notched petals, in the five distinct glands which take the place of the perigynous disk, and generally in the want of albumen to the seeds. They are remarkable also by the great tendency of the peduncles to combine with the petioles, so that the flowers, which are really axillary, appear to spring from the leaf itself at the summit of the petiole. They are all trees or shrubs, with alternate stipulate entire leaves, often white underneath. The flowers are small, in paniculate cymes or compact clusters. There are usually five sepals, petals, and stamens, regularly alternating with each other; but these numbers are, in one genus (*Tapura*), irregularly reduced. The ovary is superior with two or three cells, and two pendulous ovules in each cell; the style is simple; the fruit a rather dry drupe with one to three seeds. There are nearly twenty species, natives of tropical regions, and dispersed over both the New and the Old Worlds. They have been distributed into four or five genera, of which the principal are *Chailletia*, *Moacurra*, and *Tapura*.

**CHALAZA** (adj. **CHALAZINUS**). That part of the seed where the nucleus joins the integuments; it represents the base of the nucleus, and is invariably opposite the end of the cotyledons.

**CHALEF.** (Fr.) *Elaeagnus*.

**CHALK-WHITE.** Dull white, with a dash of gray.

**CHAMÆACTE.** *Sambucus Moutan*.

**CHAMÆBATIA.** *C. foliolosa*, the only representative of this genus, which belongs to the Rose family, is a beautiful Californian shrub, about three feet high. All the young parts of the plant are covered with small glands, which secrete a resinous fluid, having a pleasant balsamic odour. The leaves are unlike those of any other plant in the family, and bear great resemblance to those of the millifoli (*Achillea*), but are of a much harsher texture, and generally from two to three inches long. The flowers are in terminal cymes, and in size and colour very much like those of the hawthorn. The plant is in cultivation, having been introduced in 1859, and will prove a great acquisition to our gardens. [A. A. B.]

**CHAMÆBATUS.** *Rubus cactus*.

**CHAMÆBUXUS.** *Polygala Chamabuxus*.

**CHAMÆCERASUS.** *Cerasus Chamacerasus*, also *Lonicera tatarica*.

**CHAMÆCISSUS.** *Glochoma hederacea*.

**CHAMÆCISTUS.** *Rhododendron Chamæcistus*; also *Helianthemum vulgare*.

**CHAMÆCYPARIS.** A little group of Conifers forming a section of the genus *Cupressus*, from which it is separated by some botanists, and characterised by the seeds being two only under each scale. It is sometimes restricted to the American species, sometimes extended to those Japanese ones, which have been separated under the name of *Retinospora*.

**CHAMÆCYPARISSUS.** *Santolina Chamæcyparissus*.

**CHAMÆDAPHNE.** *Daphne Laureola*; also *D. Mezereum*.

**CHAMÆDOREA.** A genus of Palms, containing between thirty and forty species. They have reed-like stems marked by rings or scars, and seldom more than fifteen or twenty feet high, and one or two inches thick, and surmounted by tufts of leaves, which are either pinnate or nearly entire. All of them are natives of tropical America, inhabiting forests and forming dense masses of underwood. Their flowers are of separate sexes, borne on distinct plants, very small, and produced in great quantities on long branching spikes: the males having a cup-shaped three-lobed calyx, a corolla of three roundish petals, and containing six stamens and a rudimentary or barren ovary; and the females, a three-parted cup-shaped calyx, a corolla like the males, and a three-celled ovary crowned by three short stigmas, and without any rudimentary stamens. The fruit is a small roundish berry containing a single bony seed. The stems of most of the species serve for walking-sticks and similar purposes; and their young unexpanded flower-spikes are used by the Mexicans as a culinary vegetable, under the name of *Tepejilote*.

*C. Ernest-Augusti* is a small species, native of New Grenada, having a stem about four or five feet high. Its leaves are two feet long, wedge-shaped at the base and almost entire, being merely divided, for about half-way down the centre, into two spreading sharp-pointed plaited lobes; the foot-stalks of the leaves widen out at their bases and clasp round the stem, giving it a swollen appearance. The female flower-spikes of this species are cylindrical, about a foot long and undivided, and form a very striking object, being at first of a dark green colour and studded with red bead-like flowers; but when these latter fall away, the spike becomes a bright coral-red colour. [A. S.]

**CHAMÆDRYS.** An old herbalist's word, literally signifying 'dwarf oak,' applied to both *Taetrium Chamædrys* and *Veronica Chamædrys*.

**CHAMÆJASME.** *Androsace Chamæjasme*; also *Stellaria Chamæjasme*.

**CHAMÆLAUCIACEÆ.** A tribe of *Myrtaceæ*, sometimes considered as a separate family. They are distinguished by their heath-like habit and foliage, their one-celled ovary with few ovules, their stamens partially reduced to staminodia, and by their sepals often extended into bristles or broken up into fringes. The latter character is, however, evanescent in some genera, and the others may be more or less traced through *Backea* or its allies into the true *Myrtaceæ*. There is a considerable number of species, all Australian, and distributed under fourteen or fifteen genera, of which the principal ones are *Calytrix*, *Lhotskya*, *Verticordia*, *Chamelaucium*, *Genetyllis*, &c.

**CHAMÆLAUCIUM.** A genus of *Chamelauciacææ*, containing small heath-leaved shrubs, from South Australia. The leaves are opposite, crowded, semi-cylindrical or three-edged, with dots formed by small cavities containing essential oil. The flowers are white, shortly-stalked, axillary or terminal. The calyx has two concave mucronate bracts at the base, which enclose the bud; the calyx tube adheres to the short ovary at the base; the limb is five-cleft and subpetaloid; the petals are five; stamens ten, the alternate ones abortive, strap-shaped; capsule one-celled, indehiscent, few-seeded. [J. T. S.]

**CHAMÆLEON, BLACK.** *Cardopatum corymbosum*. —, **WHITE.** *Carlina gumifera*.

**CHAMÆMELES.** A genus of Apple-works, having the free border of the calyx truncate, and obscurely five-toothed; petals five, small, irregularly-toothed; stamens ten to fifteen; style, or appendage on the seed-vessel, simple, slightly notched at the tip; fruit one-celled; cotyledons convolute. The name means literally 'pigmy apple,' to indicate the general nature of the fruit, and the low habit of the plant. The genus was founded by Dr. Lindley, to

comprehend a dwarf shrub very like Box, a native of the sea cliffs in Madeira, having simple shining evergreen mostly entire leaves, and flowers growing in clusters, which are leafy at the base. [G. D.]

**CHAMÆMESPILOS.** *Pyrus Chamæmespilus*.

**CHAMÆMORUS.** *Rubus Chamæmorus*.

**CHAMÆNERION.** A subdivision of the genus *Epilobium*, comprising those species which have regular erect flowers (though in some cases drooping while in bud), and either club-shaped or four-cleft, not cruciform stigmas. [O. A. J.]

**CHAMPEUCE.** A genus of the Compositæ family, allied, on the one hand, to plume-thistles (*Cirsium*), and, on the other, to true thistles (*Carduus*). From the first of these it differs in the covering of the achenes being hardened, not membranaceous; and from the second, in the pappus being feathery, not simple-haired. A few of the species have narrow entire leaves with recurved margins, but the greater portion of them are hostile-looking thistle-like plants, from one to six feet high: the leaves generally lanceolate in form, smooth above, but as well as the stems covered underneath with a white cottony substance, and their margins furnished with numerous long spiny teeth; the flower-heads one to two inches in diameter, arranged in corymbs or long leafy racemes; the corollas purple or white, and enclosed by an involucre made up of many spiny-pointed scales. The fifteen known species are natives of the Mediterranean region, and extend eastwards to the Caucasus. The name also belongs to *Saxifraga Champeuca*. [A. A. B.]

**CHAMPEPITYS.** *Ajuga Chamepitys*.

**CHAMERHODOS.** A genus of the *Rose* family, allied, on the one hand, to *Potentilla*, from which it differs in having a definite number of stamens and carpels; and on the other to *Sibbaldia*, which has a double calyx composed of ten segments in two rows, while the calyx in this genus is of five segments in one row. The species are small perennial plants, seldom attaining more than a foot in height, and generally having decumbent stems which are furnished with alternate three or many-parted leaves, about half an inch long, their segments narrow and covered with greyish pubescence. The flowers are small, white or purple in colour, either single in the axils of the leaves, or numerous and arranged in leafy panicles. These plants are found in Siberia, N. China, and Tibet (where *C. sabulosa* grows at an elevation of 15,000 feet), and also in the Rocky Mountains of N. America. [A. A. B.]

**CHAMEROPS.** This is the most northern genus of Palma. It contains about ten or twelve species, inhabitants of Northern Asia, Africa, and America, and Southern Europe. They are mostly of dwarf habit, but sometimes grow as high as thirty feet.

Their leaves are shaped and plaited like a fan, having the margin deeply cut into numerous sharp-pointed divisions; and the bases of their long and generally prickly footstalks are inserted into a mass of coarse fibrous matter. Their flowers are produced in panicles from among the bases of the leaves, and are either perfect or of separate sexes, and consist of a three-parted calyx, and a corolla of three petals with from six to nine stamens attached to their bases; the fertile ones having, in addition, three distinct ovaries tapering into awl-shaped styles. The fruit is a berry about the size of an olive, containing one seed.

*C. humilis*, the only European species of the palm tribe, does not extend farther north than Nice. It is generally very dwarf, not more than three or four feet high, sending up numerous suckers from its creeping roots, and thus forming dense tufts, which, in Sicily and North Africa, take the place of our furze bushes; but if these suckers are not allowed to grow, the plant forms a trunk twenty or thirty feet high. The leaves of this Palm are commonly used in the south of Europe for making hats, brooms, baskets, &c., and for thatching houses; they also yield a large quantity of fibre, from which the French manufacture a material resembling horse-hair—for which it is substituted. The coarse fibre from the bases of the leaves is used by the Arabs for mixing with camel's hair to make their tent covers.

*C. Fortunei* grows to about twelve or twenty feet in height, and is a native of the north of China, but is perfectly hardy in the southern parts of England, a plant having attained ten feet in height in Her Majesty's garden at Osborne. The Chinese agricultural labourers use the coarse brown fibre, obtained from the bases of the leaves, for making hats and also the garment called *So-e*, worn in wet weather. [A. S.]

**CHAMÆSPHERION.** The name given to a pigmy plant of the Composite family found in W. Australia. The whole plant is about the size of a large pea, and consists of a globular dense cluster of white flower-heads, surrounded by a rosette of narrow leaves a quarter of an inch in length. The achenes have a crown-like lacerated pappus. [A. A. B.]

**CHAMARAS.** (Fr.) *Tenarium Scordium*.

**CHAMBURU.** *Carica digitata*.

**CHAMÉCERINTIER DES HAIES.** (Fr.)  
— ROSE. *Lonicera*

*taxatoria*.

**CHAMISSOA.** A genus of tropical herbs belonging to *Amaranthaceae* with alternate leaves and flowers in axillary or terminal spikes or globular heads; differing from *Amaranthus* by having the seeds furnished with a small white axil at the hilum, and the radicle of the embryo superior. [J. T. S.]

**CHAMOMILE.** *Anthem. nobilis*, some-

times written *Camomile*. —, WILD. *Matricaria Chamomilla*.

**CHAMP.** The timber of *Michelia Cham-paca*, and *M. anisala*.

**CHAMPIGNON.** The French name for mushrooms in general, but applied in this country only to *Agaricus (Marasmius) Oreades* or by mistake to very different and often dangerous species. In some parts of the country it is known under the name of Scotch Bonnets. The Champignon grows in fairy rings, generally of a few feet only in diameter. It seems to luxuriate most in a sandy soil, but occurs everywhere in exposed pastures. The pileus when moist is of a dull fawn colour, when dry of a creamy white; the stem is tough with a villous bark, the gills broad, cream-coloured, free from any attachment to the stem, and very distant. The only species with which it can be fairly confounded is *A. (Marasmius) urens*, which has narrow browner gills, and leaves a burning sensation in the throat, while the true champignon is the mildest and most sapid of fungi. It is excellent as a *f. fricassée*, or stewed like common mushrooms, and it has the great merit of drying admirably. Few comparatively are acquainted with its excellent qualities, but those who are, gladly avail themselves of it as a most welcome article for the table. The Champignon cultivee of the French is *Agaricus campestris*.

Some doubts have lately been thrown upon the safety of the Champignon, in consequence of certain Fungi, which were said to have proved fatal, having been referred to this species by Mr W. G. Smith. But the case is probably analogous to that mentioned under *BLUZZA*. It may have been mixed with species which proved fatal. [M. J. B.]

**CHAMPIONIA.** A genus named after the late Lieut.-Col. Champion, who was mortally wounded at Inkerman, containing a single species, an undershrub from *Ceylon*, belonging to the *Cyrtandraceae* division of *Gonacerae*, having opposite oblong leaves, and short axillary trichotomous peduncles, bearing white glabrous rotate corollas longer than the calyx, and having a very short tube, and a four-parted limb. There are four equal stamens and no hypogynous glands. The ovary is one-celled with two parietal placentae; and the style filiform with a capitate stigma. The oblong capsular fruit exceeds the persistent calyx; it is one-celled and contains many ovate seeds with a reticulated testa. [W. C.]

**CHANDELIER TREE.** *Pandanus Can-de-labrum*.

**CHANNELLED.** Hollowed out like a gutter, like many leaf-stalks.

**CHANTARELLE.** The French name for *Cantharellus cibarius*, adopted in this country. The genus *Cantharellus* is distinguished from *Agaricus* by the gills of the latter being replaced by veins which are frequently branched, and if they ever approach the appearance of gills, they are distinguished by their very obtuse edge,

the shorter ones not being distinct as in mushrooms, but connected with the longer as if immediately given off by them. The Chantarelle is a common though seldom an abundant inhabitant of our woods. The rich yolk-of-egg yellow and fragrant fruitly smell at once distinguish it. It is rather acrid when eaten raw, but makes an excellent fricassée if steeped before dressing in boiling milk, and then stewed very gently. It is, however, of far less frequent use in this country than on the continent, where it is highly esteemed. We are not aware that there is any deleterious fungus with which it can be confounded. [M. J. B.]

CHANVRE. (Fr.) *Cannabis*. — D'EAU. *Budens tripartita*. — SAUVAGE. *Galeopsis Tetrakii*.

CHANVRINE. (Fr.) *Eupatorium cannabinum*.

CHAPEAU D'ÉVÊQUE. (Fr.) *Epimedium alpinum*.

CHARACEÆ. A small natural order of Acrogens consisting of two or at most three genera. The species are all aquatic, and are found in almost all parts of the world, but are most common in temperate countries. In the genus *Najas*, the structure of the plant has much resemblance to that of *Cladophora*, which circumstance, combined with the aquatic habit, has caused these plants to be associated with *Algae*. In *Chara*, however, the axis is coated with tubes, and a large quantity of calcareous matter is deposited upon them. The branches are given off in whorls, those of the fruit-bearing branchlets, however, being imperfect on the outer side. The species are either monœcious or dioecious, the two kinds of fruit being often seated close to each other. The female fruit consists of an ovate nucleus externally coated with spirally-arranged tubes, the tips of which are free and look like so many stigmas, and secondly with a firm spirally-ribbed integument, the cells of which abound in starch granules. The male fruit is globose and brick-red, the surface being divided into eight equal areas consisting of tubes radiating from a common centre. From each of these a short tube is given off within the eight tubes, meeting in the centre, and joined to a cellular mass, which is supported by a ninth bell-shaped process which is fixed by the broader end to the plant, and keeps the globe from falling prematurely. At this point of junction a number of jointed threads are attached, each cell of which contains a spiral spermatoid with two long slender thong-shaped processes at one end, by means of which they move about. Wallroth asserts that he has seen the globules vegetate, a circumstance which is not impossible after they have performed their function. A more common mode of reproduction is by means of little tuberciform bodies attached to the creeping roots. Each articulation in these plants has a distinct system of circulation

which seems to be connected with the manner in which the grains of chlorophyll are arranged on the walls of tubes, a free longitudinal colourless space being left round which the juices circulate from the base upwards at the rate of about two lines in a second. An ordinary microscope is amply sufficient to show this interesting phenomenon. A little alcohol, as also many other chemical substances, at once arrests the motion, as is also the case when the distribution of the chlorophyll is disturbed. We know of no use to which these plants can be applied. The smell which they emit resembles that of sulphuretted hydrogen, and it is to this cause probably that they have an evil report as productive of fevers. Their nucules, known to mineralogists under the name of *Gyrogonites*, are found for the first time in the lower freshwater formations. [M. J. B.]

CHARACTER. A short phrase expressing the essential marks by which a given plant or group of plants is distinguished from others. A specific character distinguishes one species from other species; and so on.

CHARAGNE. (Fr.) *Chara*.

CHARBON. (Fr.) *Uredo Carbo*.

CHARDINIA. A genus of the Composite family with a single species, *C. ceranthemoides*, which is a pretty little annual herb, a few inches high, found in Asia Minor and Persia. It has alternate lance-shaped entire leaves, nearly an inch long, covered with white pubescence; and twigs terminating in solitary silvery flower-heads, which when mature are nearly an inch across, and owe their beauty to the shining chaffy lance-shaped pappus scales which crown the cylindrical striate achenes, and are nearly half an inch in length. In the closely-related genus *Xeranthemum* the inner scales of the involucre are much longer than the others, bent out at the top, and often of a bright pink colour, so that they look like ray florets; here, however, the inner scales are erect like the outer, not much longer, and of the same silvery hue. [A. A. B.]

CHARDON. (Fr.) *Carduus*. — A' BONNETIER. *Dipsacus fullonum*. — ARGENTE'. *Silybum Marianum*. — ÉTOILE'. *Centaurea Calcitrapa*. — HÉMORRHOÏDAL. *Carduus arvensis*. — MARIE. *Silybum Marianum*. — ROLAND. *Eryngium*

CHARDS. The late summer blanched leaves of the Artichoke, *Cynara Scolymus*.

CHARIANTHUS. A genus of *Melastomaceæ* from the West Indies. Erect shrubs with opposite stalked five-nerved leaves, generally entire. Flowers purple in a trichotomous corymbose cyme; calyx-tube adhering to the ovary, its limb slightly four-lobed; petals four; stamens eight; fruit a globose berry depressed in the centre, with four cells and numerous seeds. [J. T. B.]

**OKARINIE.** A genus of the Compositæ, order, having the heads of flowers surrounded by a covering of scales in two rows, forming an involucre, those of the outer row being plane, those of the inner keeled; the receptacle or part supporting the flowers is pitted, the pits slightly toothed at the margin; the fruit is broadest at the upper part, having a border composed of one row of hairs. The name is derived from the Greek word signifying 'graceful' or 'elegant.' The only species, *O. heterophylla*, is an annual, a native of the Cape of Good Hope, having the stem erect, striated and hairy, all the leaves stalkless, the lower ones opposite, those at the upper part of the stem alternate, narrow lance-shaped, and the heads of flowers yellow in the centre, and violet at the circumference. [G. D.]

**CHARLES'S SCEPTRE.** *Pedicularis Sceptum* Carolinum.

**CHARLOCK.** *Sinapis arvensis*. — **JOINTED.** The wild Radish, *Raphanus Raphanistrum*.

**CHARLWOODIA.** A genus of *Liliaceæ*, closely allied to *Cordylina* and *Dracæna*, with the former of which it is, indeed, often associated. Dr. Planchon, in his recent revision of the genera of this group of plants, considers it a well-marked genus, sufficiently distinguished from *Dracæna* by the numerous ovules in each cell, and from both *Dracæna* and *Cordylina* by the persistent perianth, and by the remarkably biserial insertion of its lobes, which are very much imbricated in their activation. The general habit is that of the *Cordylina*s. The type of the genus is *C. congesta*, an Australasian species, of elegant habit, with elongate nervously-striate leaves, and crowded many-flowered panicles. Three or four other species are associated with it. [T. M.]

**CHARME COMMUN.** (Fr.) *Carpentus Botulus*. — **HOUBLON**, or **D'ITALIE.** *Ostrya vulgaris*.

**CHARRAE.** The Arabian name for the Trumpet-Gourd, *Lagenaria vulgaris clavata*.

**CHARTACEOUS.** Having the texture of writing-paper.

**CHARTOLOMA.** A genus of *Crucifera*, allied to *Jasatia*, but with the radicle of the embryo bent over the edges of the cotyledons, not over the back of one of them. The only species, *C. platycarpum*, is an annual, with oblong sinuate-toothed leaves, yellow flowers, and large deffexed pods, which are eight or ten lines long, by six or eight broad, and are indehiscent, one-celled, and one-seeded. [J. T. S.]

**CHASSE-BOSSÉ.** (Fr.) *Lysimachia vulgaris*.

**CHASSE-RAGE.** *Lepidium graminifolium*.

**CHASTE TREE.** *Vitis Agnus-castus*.

**CHÂTAIGNE D'EAU.** (Fr.) *Trapa natans*.

**CHÂTAIGNIER.** (Fr.) *Castanea vulgaris*.

**CHATE.** The hairy Cucumber, *Cucumis Chate*.

**CHAUBARDIA.** An obscure genus of Orchids, apparently allied to *Masillaria*. It is said to have altogether the habit of *Xerostictia*.

**CHAUDRON.** (Fr.) *Narcissus Pseudo-Narcissus*.

**CHAULMOOGRA.** The seeds of *Gynocardia odorata*.

**CHAUSSÉ-TRAPPE.** (Fr.) *Centranthus Calceitrapa*.

**CHAVICA.** A genus of *Piperaceæ*, producing two important plants, namely, the Long Pepper and the Betel Pepper. The genus is distinguished from the true peppers (*Piper*) by its perfectly unisexual flowers, which are sessile on spikes placed opposite the leaves, each flower being protected by a stalked quadrangular peliote bract. *C. Bazarbighi* is largely distributed in India, where it is cultivated to furnish the Long Pepper of the shops, which consists of the spikes of flowers which, while yet immature are gathered and dried in the sun. The natives employ them for various medicinal purposes, as also the roots, and the stem cut into small pieces. In chemical composition and qualities, Long Pepper resembles ordinary black pepper, like which

Chavica Betle.

it contains *piperin*. The Long Pepper which is imported by the Dutch is said to be produced by an allied species, *C. officinarum*. *C. Betle* and *C. Siriboa* furnish the betel already mentioned under **ARECA**: which see. The betel leaf is chewed with lime, and a slice of the Areca nut. The saliva is tinged of a bright red in consequence. It acts as a powerful stimulant to the digestive organs and salivary glands, and causes, when swallowed, giddiness and other un-

symptoms persons unac-  
customed to its use. [M. T. M.]

CHAW-STICK. *Gouania domingensis*.

CHAY-ROOT. *Oidenlandia umbellata*.

CHEAT or CHESS. An American name for *Bromus secalinus*.

CHEESE RENNET. *Galium verum*.

CHEESEROOM. The common name in some parts of the country for *Agaricus arvensis*, or Horse Mushroom. This fungus grows in large rings, often many yards in diameter, and in some years, as in the wet summer of 1860, occurs in extraordinary abundance. It is known from true mushrooms by its large size, paler gills, generally thick rings, which are double at the edge, but especially by their turning yellow when bruised. It constitutes the greater part of the mushroom baskets in the Covent Garden market, and is consumed in large quantities in Leeds and other important towns in the north. When properly dressed and eaten in moderate quantities with plenty of bread, to insure mastication, these Horse Mushrooms are an excellent article of food, though they occasionally prove unwholesome, partly from over-indulgence, and partly from their having undergone decomposition before use. The term is sometimes applied to species of *Boletus*, several of which are highly dangerous. [M. J. B.]

CHEILANTHEÆ. A section of polypodiaceous Ferns, in which the sori are punctiform at the apices of the veins, and covered by indusia, which, — sometimes short and rounded, sometimes elongated continuous and therefore pteroid — consisting of portions of the margin inflected over them, are therefore necessarily transverse to the margin of the frond or of its segments. [T. M.]

CHEILANTHES. A genus of polypodiaceous Ferns of the group of *Cheilanthes*, which it typifies. The species, which are numerous and scattered over the tropical and temperate regions both of the Old and New Worlds, generally inhabiting dry rocky situations, are much varied in aspect, and for the most part are dwarf plants of tufted habit, with more or less compound fronds, the under surface in some cases being covered with silvery or gold-coloured powder, as in *Gymnogramma*. The distinguishing features of the genus consist in its producing small punctiform sori at the ends of the veins close to the margin of the frond, the margin itself becoming membranaceous, and bent over them to form the indusia, which are either linear and continuous, or take the shape of roundish lobes. The veins are free. *Cheilanthes* has considerable affinity with *Notholaena*, the species of which possess a similar habit, but have naked or non-indusiate sori. Owing, however, to the different degrees in which the margin becomes attenuated and reflexed, it is sometimes not easy to decide between the

two. *C. argentea*, a pretty dwarf tripartite silvery species, is found in Siberia; *C. fragrans*, a dwarf bipinnate species, whose fronds have a grateful anthoxanthoid or new-hay-like odour, occurs throughout the region of the Mediterranean, and reaches as far north as Switzerland; whilst Arabia, Abyssinia, South Africa, India, the Eastern Islands, Australasia, North and South America, and the West Indies, yield a variety of species, some of which, like *C. tenuifolia*, are distributed over a very wide area. One of the most beautiful species, and one which is familiar in gardens, is *C. farinosa*, a fine bipinnatifidly-pinnate plant, with tallish fronds silvered beneath and having black stalks. A peculiar group of the species has sometimes been separated under the name of *Myriopteris*; in this, the segments are small, roundish, pouch-shaped, the indusium entire and almost closing over the back of the segment, which, when reversed, looks not unlike a small roundish watch-pocket. The difference is hardly important enough to warrant their separation. [T. M.]

CHEIRADENIA *cuspidata* is a small Demerara Orchid with the aspect of some equitant *Oncidium*. It has the lateral sepals adnate to the prolonged foot of the column, a pair of solid pollen masses, and a round lip bearing five processes near the margin, arranged like the fingers of an expanded hand: a circumstance alluded to in the name of the genus.

CHEIRANTHERA. A genus of *Pittosporaceæ*, containing four Australian undershrubs, with flexuose or twining branches, and narrow leaves. The flowers are blue, in terminal corymbs or cymes, or solitary, drooping from slender terminal pedicels. Sepals, petals, and stamens five, the anthers longer than the filaments, all turned to one side, and opening by two pores at the top. Ovary two-celled; seeds nearly globular. [J. Br.]

CHEIRANTHUS. A genus of Cruciferous flowers, all so nearly resembling in habit and characters the common species, *C. cheiri*, the Wallflower, as to be easily recognised. This is a native of all Southern Europe, growing on old walls, in quarries, and on sea-cliffs. In its wild state the flowers are always single and of a bright yellow colour, but the varieties obtained by cultivation are of various tints, many of them beautiful, and all fragrant, especially in the evening. Seeds of numerous beautiful varieties are annually imported from Germany; and small gardens, in which the supply of ornamental early summer flowers is limited, may be made very gay by planting them liberally with these German wallflowers. The wallflower has long been a favourite cottage-garden flower, and has been praised in many a rustic lay; it is supposed by many to be the *Viola* of the Latin poets. Its French names are *Girofle jaune*, *Violier*, *Ranuncule*, *Rameau d'or*, *Baton d'or*, &c.; German, *Leucoja*. Several other species are also worthy of cultivation. Among these the

*Groffes de Delle* of the French, perhaps a variety of *C. limifolius*, forms small tufts, the extremities of which are covered with flowers which, during expansion, pass through several shades of purple; it continues in bloom during a great part of the year. *C. Marshallii*, a low tufted plant with bright evergreen leaves and numerous large orange-coloured flowers, blooms early in the year. All these, and several other species, are well suited for adorning rock-work. [C. A. J.]

**CHEIROGLOSSA.** A name under which *Ophioglossum palmatum* was proposed to be separated from the other species of this genus of Ferns. [T. M.]

**CHEIROPLEURIA.** A synonym of *Anapausia*, applied to *A. Vesportillo* and *A. bloupsie*, two Ferns which are remarkable in bearing fronds of a form resembling bats' wings. [T. M.]

**CHEIROSTEMON.** The Hand-flower tree, or *Macpalochitiquahuitl* of the Mexicans, is the sole species of this genus of Sterculiads. The plant, *C. platanoides*, is a tree growing thirty or more feet in height, and having plane-like leaves of a deep-green colour on the upper surface, but covered underneath with a rust-coloured scurf composed of star-like hairs, each leaf being about six inches long by five broad, deeply indented at the base and divided at the margin into from three to seven blunt, rounded lobes. Its flowers are two inches

*Cheirostemon platanoides* (flower).

long by as much broad, and are destitute of a corolla, but have a leathery, rusty-red, cup-shaped calyx, deeply cut into five broad, sharp-pointed divisions, the bottom of the cup having five bright yellow cavities which secrete a quantity of sweet fluid. The arrangement of the stamens is most remarkable; they are of a bright-red, and united together for about one-third of their length (four inches), when they separate into five curved claw-like rays, and thus bear some resemblance to the human hand. The club-shaped style

emerges from the centre of the stamens, and is terminated by a pointed stigma. The fruit is five-cornered, and splits open in five places when ripe, allowing the escape of the numerous seeds.

A solitary specimen of this tree was first discovered growing near the town of Toluca in Mexico. It was of great age, and an object of veneration among the Indians, both on account of the remarkable structure of its flowers, and because they supposed that no other tree of the kind existed elsewhere; but forests of it have since been discovered near the city of Guatemala, from whence it is probable that the Indians of Toluca had transported it in very early times. [A. S.]

**CHEIROSTYLIS.** A genus of terrestrial Orchids, consisting of little plants with the habit of *Anacrotolus*, to which it is nearly allied. Its most distinguishing character is having the three sepals united into a short tube, from the front of which hangs down a lip divided into narrow lobes. The column, moreover, has four arms, half its own, and half belonging to the stigma.

**CHELIDONE PETITE.** (Fr.) *Ficaria verna*, also known as *Ranunculus Ficaria*.

**CHELIDONIUM.** The Greater or Common Celandine, a plant frequently found in this country in the neighbourhood of villages or old ruins, is the only species of this genus of the Poppy family, and is not to be confounded with the Lesser Celandine (*Ficaria*). The Common or Greater Celandine is a glaucous hairy annual plant, with pinnately-lobed leaves, small yellow flowers in a loose umbel, and a fruit, consisting of a long pod, bursting from below upwards by two valves, and containing a number of seeds with a small crest on them, near to the place where they are attached to the interior of the pod. The whole plant is full of a yellow juice which is of an acrid poisonous nature, and has been used in certain diseases of the eye, and as a caustic to destroy warts, &c. [M. T. M.]

**CHELIDOSPERMUM.** A section of the genus *Pittosporum*, containing a few species from New Guinea, with the calyx deeply five-parted, valvate, and the seeds with long seedstalks. The leaves are oblong; the flowers grow in a pedunculated terminal umbel; and the capsule is two-seeded, with leathery valves. [J. T. S.]

**CHELONANTHERA.** *Pholidota*.

**CHELONE.** A small genus of Linariads, very closely allied to the *Penstemon*, from which, however, it is easily distinguished by its imbricated winged seeds, by its sterile fifth stamen being shorter than the other four, and by its flowers being arranged in short dense bracted spikes. The form of the corolla in this genus is also very distinct, the broad keeled upper lip and scarcely open mouth giving it some resemblance to the head of a tortoise or turtle, to which feature are due both its scientific appellation and the popular American name of Turtle-head. The best-

known representative of this genus is the *C. obtusa*, a perennial with creeping roots, erect smooth bluntly four-angled stems, opposite serrated lanceolate leaves varying considerably in breadth and acuteness, and flowers in terminal spikes, with corollas mostly of a rosy-purple colour. The so-called *C. glabra* is now regarded as but one of the forms of *C. obtusa*. *C. Lyoni*, with the same habit, has smaller flowers and longer and thinner leaves. *C. nemorosa* seems to be intermediate between *Chelone* and *Pentstemon*, having the winged seeds of the former genus, with the inflorescence and habit of the latter. It has ovate serrated leaves, and dull purple pentstemon-like flowers produced from the upper axilla. It is proper to note that several popular border flowers pass for *Chelones* which are in fact true *Pentstemons*; as examples may be cited the *Pentstemon barbatus*, *P. campanulatus*, and *P. contranthifolius*, all of which have been improperly classed under the present genus, though they possess none of its distinguishing features. [W. T.]

CHEMISE DE NOTRE-DAME. (Fr.) *Cyrtoglossa cyprium* and *Cardamine pratensis*.

CHENA, or CHAINA. An inferior kind of Indian Millet, *Panicum pilosum*; also sometimes applied to *Panicum millaceum*.

CHÊNE. (Fr.) *Quercus*. — A' GRAP-PES. *Quercus pedunculata*. — ANGOUMOIS. *Quercus Tauzin*. — A TROCHETS. *Quercus sessiliflora*. — AU KERMES. *Quercus coccifera*. — BROSEE. *Quercus Tauzin*. — COMMUN. *Quercus pedunculata*. — CYPRE'S. *Quercus fastigiata*. — DES PYRENEES. *Quercus fastigiata*. — GREG. *Quercus Agilope*. — NOIR D' AMERIQUE. *Catalpa longissima*. — PETIT. *Teucrium Chamædrye*; and also *Vernonia Chamædrye*. — QUEROITRON. *Quercus tinctoria*. — ROURE. *Quercus sessiliflora*. — VE'LANI. *Quercus Agilope*. — VERT or YEUSE. *Quercus flex*. — TAUZIN or TOZA. *Quercus Tauzin*. — ZANG or ZEEN. *Quercus Mirbeckii*.

CHENILLETE. (Fr.) *Scorpiurus*.

CHENOPODIACEÆ. (*Chenopoda*, the Goose-foot family.) A natural order of Monochlamydeous Dicotyledons, characterising Lindley's Chenopodial alliance. Herbs or undershrubs with alternate sometimes opposite leaves without stipules, and small flowers which are sometimes unisexual, i.e. have stamens and pistils in separate flowers. Perianth (calyx) deeply divided, sometimes tubular at the base, persistent; stamens inserted into the base of the perianth and opposite to its divisions. Ovary free, one-celled, with a single ovule attached to its base. Fruit an utricle (inflated) or an achene, sometimes succulent; embryo curved round mealy albumen, or spirally curved without albumen. Inconspicuous plants found in waste places in all parts of the world, but abounding in extra-tropical regions. Many of them, as species of *Salsicoria* and *Salt-*

it salt-marshes in the northern of Europe and Asia. Some of them are used as potherbs, for instance, Spinach, (*Spinacia oleracea*), Orach (*Atriplex hortensis*), Beet (*Beta vulgaris*), English Mercury (*Chenopodium Bonus Henricus*), Australian Spinach (*Chenopodium crassum*). The Mangold-wurzel is a variety of beet used for the food of cattle. The beet is much cultivated in France for its sugar. Some of the plants yield soda, others supply essential oils which render them useful in cases of worms and in spasmodic diseases. The seeds of *Chenopodium Quinoa* are used as food in Peru. They abound in starch, but have a bitterish taste. The seeds of *Chenopodium Bonus Henricus* are used in the manufacture of shagreen. There are seventy-four known genera and 533 species. Illustrative genera: *Salsicoria*, *Atriplex*, *Spinacia*, *Beta*, *Bittum*, *Salsola*, *Chenopodium*. [J. H. B.]

CHENOPODIUM. A genus of annual and perennial herbs giving its name to the natural order of Chenopoda, and chiefly remarkable for the weedy character of the species composing it, of which the Common Goosefoot, a plant found everywhere in waste places, with triangular leaves covered with a whitish meanness, and numerous small flowers in terminal clusters, is an example. It includes, however, a few species interesting for their utility, and one which has some merit as an ornamental plant. The latter is *C. Atriplex*, a tall branched annual of erect pyramidal habit, growing four to five feet high, with reddish stems, rhomboidly-ovate and often sinuate leaves, covered while young with a glittering purple meal, and numerous small flowers in terminal compound spikes of a dark-purple colour, and also clothed with purple meal. *C. ambrosioides*, or Mexican Tea, the *Ambrosia ambrosioides* of some botanists, a tropical species, contains an essential oil to which it owes tonic and antispasmodic properties; and *C. anthelminticum*, a species differing from the preceding, of which it is perhaps but a variety, chiefly in its leaves being more deeply cleft, and the flower-spike mostly leafless, yields the wormseed oil, a popular vermifuge in the United States. The species to which the greatest interest attaches is, however, *C. Quinoa*, indigenous to the Pacific slopes of the Andes, where it is largely cultivated in Peru and Chili for the sake of its seeds, which are extensively used as an article of food. They are prepared either by boiling in water like rice or oatmeal, a kind of gruel being the result, which is seasoned with the Chili pepper and other condiments; or the grains are slightly roasted like coffee, boiled in water and strained, the brown-coloured broth thus prepared being seasoned as in the first process. This second preparation is called 'carapique', and is said to be a favourite dish with the ladies of Lima. However prepared, the Quinoa is unpalatable to strangers, though it is probably a nutritious article of food

from the amount of albumen it contains.

*odorata*. —, WILD *Charophyllum sylvestre*.

which is that employed as roon, and a dark-red fruited one called the Red Quinoa. A sweetened decoction of the seeds of the latter is used medicinally, as an application to sores and bruises, and cataplasms are also made from it. This species attains a height of four to five feet, and has a stout furrowed branched stem, large triangular-ovate deeply-venate leaves, on long foot-stalks, and densely-clustered small green flowers, produced in axillary and terminal panicles. Botanically, the genus *Chenopodium* is distinguished by a five-parted perianth, five stamens, two styles crowning the ovary which contains a single round flattened seed. [W. T.]

CHERAMELLA. An Indian name for the subacid fruits of *Cicca disticha*.

CHERIMOYER. *Annona Cherimolia*, a delicious Peruvian fruit.

CHERMESINE. A kind of crimson.

CHE-ROOT. *Oldenlandia umbellata*.

CHERRIS. An Indian name for the resinous exudation of the Hemp, *Cannabis sativa*.

CHERRY. A well-known fruit produced from cultivated varieties of the Wild Cherries, *Cerasus Avium* and *C. vulgaris*. —, BARBADOS. *Malpighia glabra*. —, BASTARD. *Cerasus Pseudo-cerasus*. —, BEROO or BRUSH. *Trochocarpa laurina*. —, BIRCH. *Betula lenta*. —, BIRD. *Cerasus Padus*. —, CHOKER. *Cerasus virginiana*; also *C. serotina*, *hematula*, and *borcalis*. —, OLAMMY. *Cordia Collococca*. —, COW-HAGE. *Malpighia urens*. —, CORNELIAN. *Cornus mascula*. —, GROUND. *Cerasus Chamaceranus*; also an American name for *Physalis*. —, HOTTENTOT. *Cassia Marroccana*. —, NATIVE, of Australia. *Exocarpus cupressiformis*; —, of N. S. Wales. *Nelivris tugens*. —, WINTER. *Physalis Alkekengi*; also sometimes applied to *Physalis angulata* and *Cardiospermum Halicacabum*.

CHERRY-CRAB. A variety of the Siberian Crab, *Pyrus Malus baccata*.

CHERRY-LAUREL. *Cerasus Lauro-cerasus*.

CHERRY-PEPPER. *Capsicum cerasiforme*.

CHERRY-PIE. *Epilobium Aitruum*; in gardens the *Hottentoe*.

CHERUL (Fr.) *Stum Sicularum*.

CHERVIL. A garden potherb, *Charophyllum sativum*, also called *Anthriscus Cerefolium*. The name Chervil is also applied generally to the plants referred to *Charophyllum*. —, GREAT. *Myrrhis odorata*. —, NEEDLE. *Scandix Pecten veneris*. —, FARSNIP. *Charophyllum bulbosum*, or *Anthriscus bulbosus*. —, SWEET. *Myrrhis*

CHERVIS. (Fr.) *Stum Sicularum*.

CHESNEYA. A genus of dwarf woody plants, belonging to the pea-flowered *Leguminosae*, nearly related to *Calophaca* and *Cohutea*, from both of which it differs, in having the spaces between the seeds in the pod occupied by a spongy pith-like substance. The leaves are alternate, unequally pinnate, with from three to nine pairs of wedge-shaped leaflets, about half an inch long, and downy. The flower-stalks are axillary, bearing on their apex one to three yellow or violet-coloured flowers, whose tubular calyces are curiously swollen above at the base. The pods are from one to two inches long, roundish, or somewhat flattened, containing four to six seeds. There are about eight species known: one of them, *C. cuneata*, found in Tibet at an elevation of eight to twelve thousand feet, but the greater portion in W. Asia, and chiefly in Persia. [A. A. B.]

CHESTNUT. The common name for *Castanea*. —, BORSE. *Æsculus Hippocastanum*. —, MORETON BAY, or NEW HOLLAND. The large fleshy seeds of *Castanospemum australe*. —, SPANISH. *Castanea vesca*, the fruits of which are known as Sweet Chestnuts. —, TAHITI. *Inocarpus edulis*. —, WATER. *Trapa natans*. —, WILD. A name given by the settlers at the Cape to the seeds of *Brabejum*. —, YELLOW. *Quercus Castanea*.

CHESTNUT OAK. *Quercus Castanea*; also sometimes applied to the timber of the sessile-fruited English oak, *Quercus sessiliflora*.

CHEVEUX DE VENUS. (Fr.) *Adiantum Capillus-Veneris*; also applied to *Ouscuta major*, and *Nigella damascena*. —, DU DIABLE. *Ouscuta major*.

CHEVREFEUILLE. (Fr.) *Lonicera*. —, DES BOIS. *Lonicera Periclymenum*. —, D'ITALIE. *Lonicera etrusca*. —, DE VIRGINIE. *Lonicera sempervirens*.

CHEVRILLE. (Fr.) *Lactuca perennis*.

CHEVREUILA. A small genus of *Compositae multicaues*, containing a few species from Chili and Brazil. They are mostly of procumbent habit, with entire or sinuate leaves rising from the rootstock, and a naked peduncle surmounted by one head of flowers, those of the disk being males, and those of the ray females. One species, *C. hypopodioides*, occurs in the Falkland Islands, where, however, it is scarce. The genus *Leucopodium*, founded by Gardner on one of his Brazilian plants, is better included in the present genus. [J. Br.]

CHEYNIA. *Balaustion*.

CHIAZOSPERMUM. A genus containing an annual herb from temperate Asia, allied to *Hypocnemum*, and like it forming a connecting link between the orders *Papaveraceae* and *Fumariaceae*. It differs from *Hypocnemum* by having the seeds somewhat

four-aided, each side with a cross-marked elevation. [J. T. S.]

**CHIBOU RESIN.** A product of *Bursera gummiifera*.

**CHICASAW PLUM.** *Cerasus Chicasa*.

**CHICHA.** *Sterculia Chicha*, the seeds of which are eaten as nuts by the Brazilians; also a colouring-matter obtained from the leaves of *Bignonia Chica*.

**CHICHE.** (Fr.) *Lathyrus Cicera*.

**CHICKEN-WEED.** A name under which *Roccella tinctoria* has been sometimes imported. Also *Stellaria media*.

**CHICHOW.** The seeds of *Cassia Absus*, an Egyptian remedy for ophthalmia.

**CHICKRASSIA.** A latinised version of the Bengalee name of a lofty Indian tree, belonging to the order *Cedrelaceae*. The leaves are pinnated; the flowers large, in terminal panicles with ten stamens united by their filaments into a tube. Ovary three-celled, placed on a broad disc, with pendulous ovules, arranged in two rows. The fruit is a capsule opening from above downwards by three valves, leaving a central column. The seeds are winged. The wood of *C. tabularis* is close-grained, light-coloured, and elegantly veined; hence it is in much request by cabinet makers, who call it Chittagong wood, though there are other woods with a similar appellation. The bark of this tree is astringent but not bitter. [M. T. M.]

**CHICKWEED.** The common name for *Aisne*. The well-known weed of this name is *Aisne*, or *Stellaria media*. —, **BASTARD.** *Rufonia tenuifolia*. —, **FORKED.** *Anychia dichotoma*. —, **INDIAN.** An American name for *Mollugo*. —, **MOUSE-EAR.** The common name for *Cerastium*; also specially *C. vulgatum*. —, **SEA.** *Arenaria peploides*. —, **SILVER.** *Paronychia argyrocoma*. —, **WATER.** *Montia fontana*; also sometimes applied to *Malachium aquaticum*, and *Callitriche verna*.

**CHICO.** A kind of beer, made in Chili from the Indian corn, *Zea Mays*.

**CHICON.** (Fr.) *Lactuca sativa*.

**CHICORÉE.** (Fr.) Succory, *Cichorium Intybus*. —, **FRISÉE.** Curled Endive, a variety of *Cichorium Endivia*.

**CHICORIA DE LA TIERRA CALIENTE.** A South American name for *Achyroperus sessiliflorus*.

**CHICORY.** *Cichorium Intybus*, or Succory.

**CHICOT, or CHICHOT DU CANADA.** (Fr.) *Gymnocladus canadensis*. The term Chicot is also applied to the seeds of *Moringa pterygosperma*.

**CHIENDENT.** (Fr.) *Cynodon Dactylon*. —, **A' BALAIS.** *Andropogon Ischamum*. —, **A' CHAPELET.** *Avena bulbosa*. —, **DES BOUTIQUES.** *Triticum repens*.

**CHILLI.** The fruit of *Capsicum annuum*, and other allied species.

**CHIOLOCARPUS.** An imperfectly known genus of climbing shrubs, natives of Java, with a salver-shaped corolla, capitate stigma, and a capsular fruit. The genus is referred to the *Apocynaceae*. [M. T. M.]

**CHILODIA.** A genus of *Labuteae*, containing a single species, a native of New Holland. It is a branched glabrous or slightly pubescent shrub, with small entire linear-sessile leaves and single flowered axillary peduncles, with two small subulate bracts below the calyx. The calyx is campanulate with a short striated tube, and a bilabiate limb, the upper lip being entire and the lower emarginate or bidentate. The corolla is campanulate and faintly two-lipped. There are four stamens shorter than the tube; the anthers have two smooth parallel cells, without appendages. The apex of the style is slightly bifid with sub-equal lobes. In habit and structure this genus is very near *Prostanthera*, differing only in having no appendages to the anther-cell. [W. C.]

**CHIOGLOTTIS.** Under this name stand a small number of terrestrial Australasian Orchids, bearing radical leaves in pairs and solitary galeate reddish flowers at the end of a short naked scape. Like *Caladenia* its lip is marked by prominent glands; nor, indeed, does it differ much from that genus, except in having a very broad arched dorsal sepal.

**CHILOPSIS.** A genus of *Bignoniaceae*, consisting of a single species of erect branching shrubs from Mexico. It has long linear entire alternate leaves, and beautiful flowers in terminal dense spicate racemes, on short bibracteolate pedicels. The bilabiate calyx is membranaceous, inflated, and deeply-cleft in front; the corolla-tube is dilated upwards, and the two-lipped limb is five-lobed. The four stamens are didynamous, the sterile fifth being very minute. The style is filiform, and the stigma bilobed. The pod-like capsule is two-celled, with the partition bearing the placentae contrary to the valves. The seeds are transversely winged. [W. C.]

**CHIOSCHISTA usneoides** is a leafless Indian epiphyte of the *Orchidaceae* order, with narrow, flat, green roots, which cling to the branches of trees and appear to serve the purpose of leaves, as also happens in the leafless *Angraecums*.

**CHIMAPHILA.** A small genus of *Pyrolaceae*, natives of Europe, Siberia, and North America, differing from *Pyrola* by the hairy filaments, very short style, and capsule splitting from the apex downwards with the edges of the valves not woolly. The plants, called Winter Greens in America, have woody subterranean shoots, and a short stem with a tuft of thick shining evergreen leaves, oblong, wedge-shaped, or lanceolate—in the latter case variegated with white. The scape is corymbose or umbellately branched at the apex; the

...loels one-flowered, bearing handsome, white flowers, tinged with and very sweet-scented. The leaves contain a bitter extractive matter, on which account they have been used in medicine, in North America. [J. T. S.]

**CHIMNEY PLANT.** *Campanula pyramidalis*.

**CHIMONANTHUS.** The Japan Allspice, *C. fragrans*, is the only representative of this genus of the *Calycanthus* family, and it is well-known in gardens for its early flowering and the sweet scent of its blossoms. It was introduced from China in 1766, and for a long while was known under the name of *Calycanthus praecox*, until it was shown to differ from that genus in having but ten stamens arranged in two rows; while in *Calycanthus* they are very numerous, and arranged in four rows. The Japan Allspice is a much-branched shrub, and generally treated as a wall-plant in gardens; its leaves are opposite, stalked, between oval and lanceolate in form, and very rough on the surface; they generally fall late in the autumn, but sometimes a few remain till the spring. The flowers are sessile on the branches, about an inch in diameter, and made up of a large number of pale yellow waxy petals, arranged in several rows: the inner series in one variety chocolate-coloured, and in another mottled with red. These flowers in mild winters often appear about Christmas, and last for a long time. [A. A. B.]

**CHINA ASTER.** *Callistephus chinensis*, also called *Callistemma hortensis*.

**CHINA BARK.** The bark of *Buena hecandra*, an indifferent febrifuge.

**CHINA GRASS.** The fibre of *Bolmeria nivea*, the Rhea, or Ramee.

**CHINA ROOT.** The tuberous rhizome of *Smilax China*.

**CHINCAPIN.** (Fr.) *Castanea pumila*.

**CHINCHIN.** A Chilian name for *Polygala theioides*.

**CHIN-CHON.** A gummy or glutinous matter, much used as a glue or varnish in China and Japan, and supposed to be the produce of *Plocaria tenax*.

**CHINESE SWALLOWS' NESTS.** These curious productions, which sell at such a high price in China, though they have no especial points of recommendation beyond many other gelatinous ingredients in soups, were formerly supposed to be made of some species of the rose-spired *Alga*, as *Sphaerococcus lichenoides*; but this is now ascertained to be a mistake, and it is known that they are formed of a secretion from the mouth of the bird itself. [M. J. B.]

**CHINESE TREE.** *Paonia Moutan*.

**CHINESE VARNISH.** *Rhus vernicifera*.

**CHINKWORT.** The popular name in some districts for the different species of

*Opegrapha* and their allies, which grow on the trunks of trees. These lichens are also sometimes called Letter-lichens, or Scripture-words. [M. J. B.]

**CHINQUAPIN.** An American name for *Quercus prinoides*; also for *Castanea pumila*.

**CHIOCOCCA.** A genus of the *Cinchonaceae* family, consisting of small shrubs, with a funnel-shaped yellowish corolla, concealing the five stamens, which are provided with hairs. Ovary two-celled, with two inverted ovules. Fruit a berry with two seeds. The species are remarkable for the violent emetic and cathartic properties possessed by the roots, which are administered in Brazil as a certain remedy for snake bites, though their intense action would seem to be, from the account of Von Martius, almost as dangerous as the wound they are intended to cure. The name is derived from two Greek words, signifying 'snow-berry', in allusion to the white fruit. [M. T. M.]

**CHIONANTHUS.** The Snowdrop tree of North America, or the Snow-flower, as the name implies, belongs to a genus of *Oleaceae*, and is distinguished by its deciduous leaves, and the long narrow ribbon-like segments of the corolla. The fruit is a drupe like that of the olive. *C. virginica* is a deciduous shrub or small tree, with large smooth leaves like those of a *Magnolia*, and bearing flowers in terminal panicles. It blossoms in this country in June, and is highly ornamental. [M. T. M.]

**CHIONOPHILA.** A genus of *Scrophulariaceae*, nearly allied to *Pentstemon*, but differing from that genus in its five-toothed (not five-cleft) calyx, as well as in habit. *C. Jamaici*, the only known species, found in the Rocky Mountains near the snow limit, is a small unbranched herb about two inches high, with a few smooth linear leaves which are enveloped near the base by a number of membranaceous scales. The tubular flowers grow one or two on the apex of a short scape. The fruit is not known. [A. A. B.]

**CHIP.** A material used for plaiting into various articles of ornament and use, and obtained from the leaves of the palm called *Thrinax argentea*.

**CHIUQUICHUQL.** The Venezuelan name for *Attalea funifera*, which yields the Pia-saba fibre of commerce.

**CHIRATA.** An Indian tonic, *Agathotes Chirayta*; also called Chiresta or Chiretta.

**CHIRITA.** A small genus of *Gesneraceae*, natives of tropical Asia. They are herbaceous plants with a short stock or a simple leafy stem, the leaves opposite, and the flowers solitary or umbellate, on axillary or radical peduncles. The calyx is five-lobed; the corolla tubular, the limb two-lipped. Of the four stamens the two upper are small and sterile, and the fertile pair have divaricate anther-cells cohering

laterally. The stigma is flattened and emarginate or two-lobed. The linear capsule contains many minute seeds without appendages. [W. C.]

**CHIRONIA.** A genus of the Gentian family, somewhat singularly named after Chiron, one of the reputed fathers of medicine, inasmuch as the species inhabit a district unknown in those days, to wit, the Cape of Good Hope. The genus consists of herbs or small shrubs with narrow ribbed leaves, and a corolla with a short tube, and a five-cleft bell-shaped limb with deciduous segments. The five stamens are short, inserted on the throat of the corolla and bent downwards, and the anthers open by two pores at the top. The ovary is partly two-celled, by the bending inwards of the placenta, bearing the numerous seeds; the style terminal, curved at the top, and directed away from the stamens. The capsule has a somewhat fleshy external rind, and an inner membranous one. Several kinds are in cultivation. They have for the most part pretty pink flowers. [M. T. M.]

**CHIRONIS.** (Fr.) *Stem Siarum.*

**CHIROPETALUM.** A genus of *Euphorbiaceae*, allied to *Oreton*, but differing in the stamens being united into a column, not free, and also to *Ditaxis*, which, however, has ten stamens in two tiers, instead of five in one tier. The plants are herbs or small shrubs confined to the temperate parts of South America, some of them having all their parts covered with little simple hairs. The leaves are alternate entire or serrate, generally lanceolate in form and three-nerved. The small green flowers are disposed in axillary or terminal racemes, the upper portion of the raceme being occupied by the males, which are the most numerous, the lower by the females. The calyx is five-parted, and the petals, of a like number, are three or seven-lobed. The ovary is crowned with three styles, each forked at the summit in the form of a Y, and bent back on the fruit which is three-lobed and contains three seeds. The leaves of some of the species are of a reddish-brown colour owing to the presence of colouring matter. [A. A. B.]

**CHITONIA.** A genus of West Indian shrubs of the family *Melastomaceae*, some species of which are grown in this country as ornamental stove-plants. They form shrubs or small trees, and have opposite ovate acute five-nerved leaves, and terminal panicles with three-flowered branches. The limb of the calyx is described as being in two rows, the outer consisting of awl-shaped teeth, the inner of short very blunt membranous processes, adherent to the base of the outer teeth; the anthers open by one pore only; the ovary is enclosed within the tube of the calyx, and has six compartments. [M. T. M.]

A. An Indian name for

**CHITTAGONG WOOD.** The timber of

several Indian trees, especially of *Cedrela Toona*, and *Chloroxylon tabularia*.

**CHITTAH-PAT.** The Assam name for *Lonicera peltata*.

**CHIVES or CIVES.** *Allium Schoenoprasum*, a garden esculent.

**CHLÉNACEÆ.** A small family consisting of only four genera of one or two species each, all from the island of Madagascar, and as yet but very imperfectly known. They are trees or shrubs with the habit, alternate leaves, stipules, and terminal inflorescence of some *Sterculiaceae*, of which they have also the free petals, monadelphous stamens and anthers; and the structure of the ovary fruit and seed is the same as in some genera of that family; but the calyx is said to be always three-cleft or composed of three sepals, and enclosed in a five-toothed involucre, an anomaly which has prevented the absolute union of *Chlénaceae* with *Sterculiaceae*.

**CHLAMYDANTHUS.** A name now applied to a section of the genus *Thymelæa*, in which the tubular calyx remains attached after withering and encloses the nut. The plants embraced in this section are low woody-stemmed bushes, chiefly natives of the Mediterranean regions. Their bark is very tough as in all the plants of the family to which they belong (*Thymelæaceae*). Their leaves are seldom more than half an inch long, and generally linear in form; and the flowers are small and inconspicuous in the axils of the leaves. [A. A. B.]

**CHLIDANTHUS.** A genus of South American *Amariyllids* having truncated bulbs, linear-lorate leaves sheathing at the base, developed after the flowers, and a scape, one and a half foot high, supporting an umbel of a few large fragrant flowers. The perianth has an erect cylindrical tube widened at the mouth, and a nearly equal somewhat spreading limb of six segments. The filaments of the six stamens are inserted in the points of the alternately unequal teeth of a thin membrane adhering completely to the tube and base of the petals, but partible. This membrane Dr. Herbert regarded as an incipient manifestation of the staminate cup of his pinceriform section of *amariyllids*, with which *Chlidanthus* thus becomes a connecting link. *C. fragrans*, the only species, has glaucous erect leaves about a quarter of an inch wide; its flowers are yellow, fragrant, sub-secate, with the tube two to four inches long, and the limb one inch and a half. [T. M.]

**CHLOANTHES.** A genus of *Verbenaceae* from extra-tropical New Holland, consisting of undershrubs thickly covered with opposite or ternate sessile linear and revolute leaves, and having solitary axillary flowers with short peduncles. The calyx is campanulate, five-cleft, and spreading. The tube of the corolla has a woolly ring on its interior above the apex of the ovary, and the ringent limb has the upper

lupinid, and the lower tripartite, the middle lobe being the longest. The four didynamous stamens are inserted in the corolla-tube, and the ovary is four-celled, with a slender style.

**CHLOIDIA.** Among the terrestrial Orchids with the habit of small bamboos are two species referred to *Neotua* by Swartz: *N. fava* and *N. polystachya*, the first found in swamps in Jamaica and Brazil, the second inhabiting barrens on the highest mountains of Jamaica. Both look like a *Corymbis* or *Cnemidia*. They seem to fill the same position among *Neotice* as *Evelyna* among *Epidendrea*. *C. decumbens* is six feet high; but *C. vernalis* is not more than a foot.

**CHLORA.** An annual herbaceous plant, well marked among the *Gentianaceae* by its eight-cleft flowers and eight stamens. *C. perfoliata*, called Yellowwort, the only British example, is a singularly erect slender plant, about a foot high, with but few root-leaves, opposite stem-leaves which are united at the base (connate), and stems which are forked towards the extremity, having a single flower in each fork and others crowded at the extremity. The whole plant is perfectly smooth and of a decided glaucous hue. The flowers, which are rather large, and of a delicate clear yellow, expand only during the sunshine, like the genus *Erythraea*, to which *Chlora* is allied. The whole plant is intensely bitter, and may be employed with advantage as a tonic; it also dyes yellow. It is of tolerably common occurrence in chalky pastures, especially near the sea. Two other species resembling *C. perfoliata* in habit occur on the European continent, one a native of Germany and Hungary, the other of Southern Europe. French, *Chlore*; German, *Bikerkraut*. [C. A. J.]

**CHLORÆA.** An extensive genus of terrestrial Orchids exclusively found in the southern districts of South America. Botanically they are allied to *Arethusa*, although very different in habit from that genus. Their roots are coarse fascicled glutinous fibres. The leaves are all radical. The scape is clothed with thin herbaceous sheaths. The flowers grow in spikes or racemes in the manner of the genus *Orchis*, are greenish, whitish, or yellow, occasionally marked by deep brown specks. Some thirty or forty species are known, none of which are in cultivation, although they have been occasionally introduced, among which is the plant called, in the *Botanical Magazine* (t. 2836), *Ulantha grandiflora*, the native country of which is unknown.

**CHLORANTHACEÆ.** A small family of Dicotyledons with flowers of a very simple structure, allied to those of *Piperaceæ* and *Saururaceæ*. They are trees, shrubs, or rarely herbs, with opposite leaves connected by sheathing stipules. The minute

flowers are in simple or branched terminal spikes, often articulate, as in *Gnetum*. There is no perianth. One or more stamens are adnate to the ovary when the flowers are hermaphrodite. The ovary contains a single pendulous ovule, and is crowned by a thickened sessile stigma. The fruit is a small drupe, the embryo very minute in the top of a fleshy albumen. There are but very few species, all tropical and contained in two genera: *Chloranthus* in Asia, and *Hedyosmum* in America.

**CHLORANTHUS.** A genus of tropical *Chloranthaceæ*, the only floral envelope of which is a very small calyx, consisting of one scale adhering to the side of the ovary. It consists of small evergreen shrubs, having jointed stems with tumid articulations, and opposite simple leaves with minute intervening stipules. The apparently single stamen, which is the most remarkable part of its structure, consists of three, the central one of which has a perfect two-celled anther, and the other two, one on each side of it, have only half an anther, so that they are only one-celled; or the two lateral half anthers may be deficient, leaving a single perfect stamen. They are attached to the side of the ovary immediately above the calyx. The three stamens grow together except at their points, so as to become monadelphous, which has given rise to different opinions as to their structure. The ovary is one celled, consisting of a single carpel with one pendulous ovule; and the seed has a large quantity of albumen, the embryo being very minute.

*Chloranthus inconspicuus.*

The roots of *C. officinalis*, a native of Java, occasionally seen in our hot-houses, are an aromatic stimulant, which, Dr. Blume states, has proved of the greatest service in a typhus fever of that island, accompanied with symptoms of extreme debility, languid pulse, and stupor. It was also employed most beneficially in malignant intermittent fever; and heads

there can be no doubt that it is one of the most valuable stimulants in such cases. It was given in infusion, and was usually combined with a decoction of *Cedrela Toona*. The roots are also employed there with the greatest success, mixed with carminatives, as anise, in the malignant small-pox in children. *C. brachystachys* has similar properties. [B. C.]

The detached flowers of *C. inconspicua*, which are fragrant, are used in China under the name of Chu-lan, for scenting some of the perfumed teas. They are placed with the prepared leaves in alternate layers under pressure, and thus impart their fragrance to the tea. [T. M.]

**CHLORETTE.** (Fr.) *Chlora perfoliata*.

**CHLOEIS.** A genus of Grasses, typical of the tribe *Chlorideæ*, distinguished chiefly by the spikes of inflorescence being in finger-like fascicles, rarely two, or only one. Flowers polygamous; glumes two, containing from two to six florets; lower flowers one to three, hermaphrodite; male flowers often stalked; pales with terminal awns; stamens three; styles two. Sixty-nine species are described in *Stendel's Synopsis*, and these are mostly natives of warm, dry countries, and consequently require the protection of a conservatory in Britain. *C. radiata* is a pretty annual grass, frequently cultivated in green-houses, in consequence of its ornamental and curious appearance. Many of the other species are handsome also. [D. M.]

**CHLORO.** In Greek compounds=green.

**CHLOROCHROUS.** Having a green skin.

**CHLOROPHYLL.** The green resinous granular colouring matter secreted below the surface of plants.

**CHLOROSA latifolia**, is an insignificant Javanese Orchid, allied to *Neottia* and *Cryptostylis*, from the latter of which it differs in the pollen, which is strictly powdery, and in the anther, which is terminal. It has small insignificant green flowers.

**CHLOROSIS.** One of the most formidable diseases to which plants are subject, and often admitting of no remedy, especially where it is constitutional. It consists in a pallid condition of the plant, in which the tissues are weak and unable to contend against severe changes, and the cells are more or less destitute of chlorophyll. It is distinct from blanching, because it may exist in plants exposed to direct light on a south border, but is often produced or aggravated by cold ungenial weather and bad drainage. Plants may, however, be affected by this disease as soon as the cotyledons make their appearance, and the seedlings of chlorotic plants partake often of the weak constitutions of the parent. The best culture will not always restore such plants to health. The most promising remedy is watering them with a very weak solution of sulphate of iron. Many forms exist, of

which those of clover, onions, cucumbers, and melons, are perhaps the best known. Melons have become so subject to chlorosis, from some unknown cause, that their cultivation is daily becoming more difficult; and cucumbers are still more generally affected, the fruit even partaking of the malady, and not only losing its brilliant green, but becoming distorted from gumming and partial decay. [M. J. B.]

**CHLOROSPERMEÆ.** One of the three great divisions of *Algae* characterised by the green colour of the spores. To this there are occasional exceptions, and in some of these the spores are originally green. The species are in general far less compound than in the two other orders, though in some instances the phenomena of fructification are more striking. The green powdery or gelatinous productions, which are so common upon damp walls or rocks; the curious microscopic few-celled productions which abound in our pools or infest other *Algae*; the green floating masses which form a scum upon our pools, or the shrubby tufts of the same colour in running streams or on sea rock; the slimy membranes which occur both in fresh and salt water, are so many members of the division; to which may be added, the spongy *Codiums* and the herbaceous tinted *Cuclerpes*, which often assume the more solid appearance of the more perfect *Algae*. In a few genera large quantities of carbonate of lime are deposited, so as to give them a corn-like appearance. To avoid repetition the peculiar features of each group will be stated in its proper place. In *Diatomaceæ* the spores, which are however rarely produced, their multiplication being chiefly effected by repeated cell divisions, are of a yellow brown, and in an artificial system they might be referred to the *Melanosperms*. Though, however, they are in some respects so peculiar as to stand apart from other *Algae*, they are so closely connected with *Desmidiaceæ*, that they can scarcely be separated from true *Chlorosperms*.

The spores of most members of this great division when they are first liberated are endowed with active motion, which is produced by long thorny-like appendages and by short cilia. In most cases they are very minute. Such spores are called, from their resemblance to Infusoria, *Zoosperms*. In some instances, as in *Coscinopsis*, the admixture of the contents of two contiguous cells, either in the same or different individuals, is requisite for the production of the perfect spore. In the latter case, short lateral tubes are thrown out, by means of which different threads are united, or they become adherent without any distinct connecting thread. Male organs have been found in many of the divisions. [M. J. B.]

**CHLOROXYLON.** A genus of *Cedrelaceæ*, generically distinguished by its fruit having only three cells, and splitting into three parts instead of five.

The Satin-wood tree of India, *C. Swietenia*,

forms a fine tree fifty or sixty feet in height. It is a native of Ceylon, and the Oromandel coast, and also of other parts of India. Its leaves are pinnate, consisting of numerous pale-coloured leaflets, of a somewhat egg-shaped outline, but with the two sides unequal. These leaflets are readily distinguishable from those of all the allied genera, with the exception of *Flindersia*, an Australian genus, by their substance being dotted with minute pellucid glands or oil cells. The small whitish flowers of this tree are borne in large branching panicles, growing at the ends of the young branches. They have a small five-parted calyx; five spreading petals with short stalks; ten awl-shaped spreading stamens, all of which are distinct and fertile; and a three-celled ovary, which is half buried in the disk from which the stamens rise. The fruit contains four seeds in each cell, and the seeds are prolonged at one end into a thin wing or membranous expansion.

This tree yields the Satin-wood of India, a handsome light-coloured hard wood, with a satin-like lustre, and sometimes beautifully mottled or curled in the grain, bearing some resemblance to box-wood, but rather deeper in colour. The best kind of Satin-wood, however, comes from the West Indies, and is the produce of a different but unknown tree. In 1858 the imports of this wood amounted to 248 tons, valued at 2,487: the Indian wood being in circular logs of nine to thirty inches in diameter, and that from the West Indies (St. Domingo and New Providence) in square logs or planks varying from nine to twenty inches across. The principal use of satin-wood is for making the backs of clothes- and hair-brushes, and for articles of turnery ware; the finest mottled pieces, however, are cut into veneers and used for cabinet-making and similar purposes.

[A. S.]

**CHENOOPHORA.** A name sometimes given to certain Ferns usually referred to *Alceophila*.

[T. M.]

**CHOCO.** *Sedum edule*, a tropical succulent of the Cucurbitaceous order, occasionally imported into this country.

**CHOCOLATE ROOT.** *Geum canadense*.  
— **INDIAN.** *Geum rivale*.

**CHOCOLATE TREE.** *Theobroma Cacao*. The Chocolate-nut is the seed of this tree, and the chocolate of the shops a preparation of these seeds.

**CHERADODIA.** A genus referred by Herbert to the alströmeriform Amaryllids. It has fibrous roots, numerous radical linear acute erect glabrous leaves, and a scape five to six feet high, bearing three or four smaller alternate clasping leaves, and supporting a corymb of flowers, of which the sepals and petals are very unequal in size, the one white the other tipped with red. It is a little-known plant of Chili, where it is called *Thabel*. A cold

infusion of its leaves is purgative and diuretic. [T. M.]

**CHOHO.** An Abyssinian name for *Indigofera argentea*.

**CHOIN.** (Fr.) *Schœnus*.

**CHOISYA.** A Mexican Rutaceous shrub, with ternate leaves, a paniced inflorescence, with large deciduous bracts beneath the flower-stalks; white flowers sprinkled with glandular dots; the five petals and ten stamens inserted on a short stalk supporting the ovary, which consists of five carpels fused into one. The style is short with five furrows, hairy like the ovary; stigma capitate. The fruit is a capsule with five furrows. [M. T. M.]

**CHOKE-BERRY.** An American name for *Pyrus arbutifolia*.

**CHOKE, BLACK.** *Cerasus hiemalis*.

**CHOLA.** An Indian name for Gram, *Cicer arietinum*.

**CHOLLU.** An Indian name for the grain of *Eleusine coracana*.

**CHOLUM.** The great Millet, *Sorghum vulgare*.

**CHOMORO.** *Podocarpus cupressinus*, one of the best timber trees of Java.

**CHONDRILLA.** A genus of the Compositæ family, nearly allied to the Lettuce (*Lactuca*), which has the achenes prolonged into a beak and smooth; while those of *Chondrilla* are often rough and furnished at the base of the beak with five small scales, arranged in the manner of a little calyx. The plants are herbs, with generally pinnatifid root-leaves, having a large terminal lobe and small lateral ones; those of the stem, few small and entire. The yellow flower-heads are solitary and terminating the branches, or in corymbs or leafy spikes. *C. juncea*, a native of the south of Europe, a straggling much-branched plant, is almost destitute of leaves when in flower; a narcotic gum is said to be obtained from it in the Island of Lemnos. About twenty species are enumerated, all of them weedy plants, natives of South Europe, the East, and Siberia. [A. A. B.]

**CHONDRODENDRUM.** A genus of climbing shrubs belonging to the *Montiper-maceæ*, and closely allied to *Coccolus*, from which it is distinguished by the stigmas, which are ovate and simple; by the globose fruit, which consists of one drupe, owing to the suppression of the others, and by the flat orbicular seeds with a striated margin. *C. convolvulaceum* is called by the Peruvians the Wild Grape, on account of the form of the fruits, and their acid and not unpleasant flavour. The bark is esteemed as a febrifuge. [M. T. M.]

**CHONDROHYNCHA** *roses* is a terrestrial Orchid related to *Cymbidium*, inhabiting Central America. It has long ribbed broad grassy leaves, and large dirty

purple radical flowers, with the upper sepal united to the back of the column, and the lip in the form of a large boat-shaped body. The pollen masses are four, secured in pairs to a long soft gland attached to a hard cartilaginous rosette.

**CHONDROSPERMUM.** A genus of climbing evergreen shrubs, natives of India, with opposite petiolate and three-nerved leaves; the flowers are in very short pedunculate panicles with small lanceolate bracts. The calyx and corolla consist each of four parts; the corolla has a long tube, and spreading limb, cleft into four linear clavate lobes; there are two scarcely exerted stamens, a two-celled ovary with a single erect ovule in each cell, and two very short styles or stigmas. The yellow flowers and climbing stems, together with the erect ovules, have caused this genus to be referred to *Jasminaceae*. The whole structure of the flower seems, however, to unite it more closely to *Oleaceae*. [W. C.]

**CHONDRUS.** A small genus of rose-spored *Algae*, with a forked fan-shaped frond, and the capsules, which contain several masses of spores, immersed in the frond without any definite border. The type of the genus is *C. crispus*, the true *Carrageen*. It is very common on our

*Chondrus crispus*.

coasts, as it is also on the Atlantic coast, from the shores of British America to those of Long Island. The colour varies from a dull livid purple to greenish and yellowish. [M. J. B.]

**CHONEMORPHA.** A genus of *Apocynaceae*, closely allied to *Echites*, and differing from it principally in the funnel-shaped corolla. The species are, moreover, Indian not American. The root and leaves of *C. malabarica*, a plant of Malabar, are used medicinally by the natives. [M. T. M.]

**CHOOA or CHOUA.** An Indian name for *Amaranthus frumentaceus*, and *oleraceae*.

**CHOOA.** *Pterardia dulcis*, a Malacca fruit.

**CHORDA.** A genus of dark-seeded *Algae*, with a simple cylindrical tubular frond, in the surface of which are imbedded a number of obconical spores. In *C. filum*, the frond is silmy, perfectly cylindrical, and sometimes twenty, or even forty feet in length. It is occasionally used instead of fishing lines, for which, however, it must be a poor substitute. 'It is in quiet land-locked bays,' says Dr. Harvey, 'with a sandy or somewhat muddy bottom, and in from three to six fathoms of water, that it reaches its greatest size. In such places it frequently forms extensive submarine meadows so dense as seriously to affect the passage of boats, and to endanger the life of the unfortunate swimmer who may chance to become entangled in its silmy cords, which when growing have considerable tenacity.' [M. J. B.]

**CHORDA PISTILLARIS.** A line of tissue reaching from the stigma down to the cavity of the ovary.

**CHORDARIÆ.** A natural order of dark-spored *Algae*, distinguished by their compound gelatinous frond consisting of vertical and horizontal threads variously interlaced, the cysts being contained in the substance of the frond, and not external as in *Ectocarpæ*. Some are as gelatinous as *Batrachospermum*; while *Leathesia* presents an irregular firm but hollow truffle-like mass; *Ralfsia* forms an adherent crust. They are principally inhabitants of colder regions, though species are found at Port Natal and amongst the Philippines. The spore-like cysts are often of two kinds, both producing zoospores. The tips of the terminal threads are often swollen so that they appear to be fruit. [M. J. B.]

**CHORETIS.** A genus of Mexican and Texan *Amaryllidaceæ*, with the habit of *Ismene*, and the flowers of *Hymenocallis*. The perianth has a long slender nearly straight tube, a reflexed limb of long narrow segments, and a large rotate corol lacerated at the margin, the long filaments being spreading-connivent. *C. glauca* is a beautiful species with black-coated bulbs, erect glaucous leaves, a foot and a half long and two and a half inches wide, and a scape upwards of a foot high, supporting three or four sessile flowers. The tube of the perianth is six inches long, quite slender, green, the limb three and a half inches or more, linear white-ribbed with green, the cup, or corol above an inch long, white, rotate, with large teeth between the stamens, which have long incurvo-connivent filaments attached to the upper part of the anther in a prominent callosity. *C. galvestonensis* is a smaller-flowered species from Texas, producing four-flowered umbels, the tube of the perianth and the limb each about two and a half inches long. [T. M.]

**CHORETRUM.** A genus belonging to

the order of Sandalworts. The flowers have both stamens and pistils; the divisions of the calyx vaulted and covering the five stamens; the style, or appendage on the top of the ovary, is very short, ending in a star-like surface. The name is derived from the Greek word signifying a rustic, probably in allusion to the plain aspect of the species. They are natives of New Holland, having the form of shrubs resembling our native broom. The leaves are very small and scattered, confined mostly to the vicinity of the flowers, which are also small, white, and subtended by four leaflets or bracts. [G. D.]

**CHORION.** A carpel; also the pulpy matter which fills the interior of a young seed before impregnation.

**CHORIPETALUM.** A genus of scandent shrubs or trees of the Ardisiad family, distinguished among its allies in its petals being four in number and free, not united, as well as in its racemed flowers. The leaves are alternate, shortly-stalked, and entire, generally about five inches long, between ovate and elliptical in form, and furnished with glandular dots. The small white or yellowish flowers are borne in little axillary racemes, and the berries when ripe are scarlet in colour and contain few seeds. Those of *C. undulatum* are, according to Dr. Hooker, eaten in Sikkim as well as the leaves, which are sour to the taste. This species grows to a straggling tree of sixty feet, and, along with a few others, is a common plant in the temperate regions of the Himalayas. One species is found in Ceylon; another, with small leaves, rounded at the apex and narrowed towards the base, is found in Hong Kong, the eastern limit of the genus, Java being the southern, and Bombay the western. [A. A. B.]

**CHORISIA.** A genus of small prickly-stemmed trees of the Sterculiad family, peculiar to South America. Their leaves are alternate stalked and digitate, made up of five oblong, or elliptical smooth leaflets, each from three to six inches in length. The flowers (one to three in the axils of the upper leaves) are large, rose-coloured, and composed of a bell-shaped three or five-lobed calyx; five narrow petals from one to three inches long, either entire or with crisped margins, and covered with silky hairs; a double staminal tube, the outer one short and bearing on its apex ten barren stamens, the inner much longer and bearing ten fertile stamens. The number and arrangement of the stamens serve to distinguish the genus from its allies. The fruit is a one-celled pear-shaped capsule, containing many seeds, which are covered with silky or cottony hairs. The tough bark of *C. crispiflora* is used in Brazil for making cordage; and the white cottony hairs of the seeds of *C. speciosa* are used by the Brazilians for stuffing pillows and cushions. The tree is known by the name of *Arvore de Palma* in Brazil. M. de St. Hilaire

remarks, that the cottony hairs which cover the seeds and line the walls of the fruit of many of the plants of this *Bombax* family, are used wherever they grow—whether in India, Africa, or America, for precisely similar purposes. [A. A. B.]

**CHORISMA.** The only species of this genus, *C. repens*, a little plant of the Composite family, grows on the sandy seashores, from Loo Choo and Hong Kong to Kamtschatka. The stems, about the thickness of a straw, creep along the sand and emit roots where the leaves are given off; these leaves have stalks about three inches long, and are generally three or five-lobed, but sometimes three-parted with three-lobed segments, the blades much shorter than their stalks and quite smooth. The yellow flower-heads are from one to three, supported on a stalk a little longer than the leaves. This plant is nearly related to the sow-thistles, but the peculiar habit and form of its leaves readily serve to distinguish it. It has been called *Chorina repens*, and is now placed in the genus *Ixoria*. [A. A. B.]

**CHORISTORA.** A genus of *Cruciferae*, allied to *Cakile*, but differing in the longer cylindrical pod, which breaks across into one-seeded divisions. Annual plants, natives of Siberia and the Altai, with purple, white or yellow flowers. [J. T. S.]

**CHORISTES.** A genus of much-branched Mexican shrubs, belonging to the *Cinchonaceae*. The flowers are few in number, with a top-shaped calyx, having four persistent, short divisions; a somewhat bell-shaped corolla; four stamens; a two-celled ovary, becoming a capsule, dividing from the top into two divisions, to liberate the numerous seeds. [M. T. M.]

**CHORISTOPHYLLOUS.** Separate-leaved.

**CHORISTYLIS.** A South African genus of *Escalloniaceae*, represented by a shrub with panicles of small green flowers, having five awl-shaped silky three-nerved petals, valvate in the bud, and four stamens with a fleshy connective between the lobes of the anther. The ovary is inferior, with two compartments, and surmounted by two styles, united partially at first, but ultimately becoming disjointed. The fruit is a capsule bursting into two pieces to liberate the many seeds it contains. [M. T. M.]

**CHORIZANDRA.** A genus of Cyperaceous plants, belonging to the tribe *Scelerineae*. The spikes are many-flowered, and androgynous the exterior flowers male and monandrous, the central ones solitary, female, with two to three-cleft styles. Three species are described of these little-known plants, which are all natives of Australia. [D. M.]

**CHORIZANTHE.** A genus of *Polygonoaceae*, of the tribe *Eriogonaceae*. Herbs, natives of California, or under-shrubs from Chili. Leaves alternate, crowded at the

base of the stem, woolly; inflorescence cymose, lax, or contracted into heads; involucre one-flowered, tubular, three-sided, six-toothed; perianth herbaceous, tubular, with a six-lobed limb, the lobes in two rows; stamens nine, the filaments cohering at the base; styles three; fruit a three-sided nut. [J. T. S.]

**CHORIZOPTERIS.** A name proposed for one or two Acrostichoid Ferns, now classed with *Neurocalais*, which are remarkable in having the parts of the fronds articulated, so that they readily fall to pieces when dry. [T. M.]

**CHOROZEMA**, also **CHORIZEMA**. A genus of pretty West Australian bushes belonging to the *Leguminosae*, nearly allied to *Callistachys*, but differing in having the keeled petal shorter than the wings, as well as in the inside of the pod being destitute of any pithy substance. The plants are very often to be met with in greenhouses, upwards of a dozen species being in cultivation, the greater portion of them producing their graceful elegant flowers in the spring months. The leaves are simple, either entire or with spinous teeth, generally smooth, and varying much in form. In the greater portion the flowers are in racemes, but in a few they are axillary and solitary; the pods are generally oval in form, turgid, and about half an inch long, containing a number of seeds.

The first species of the genus, *C. ilicifolium*, was found by Labillardiere in West Australia. This botanist was attached to the expedition sent by the French government in search of the lost La Perouse, and one of his excursions suffered much, with his party, for want of water; at last they met with an ample supply, and near it with this plant, which he named *Chorozema*, a name said to be derived from *choros* a dance, and *sema* a drink, in allusion to the joyful feelings of the party on meeting with a supply of water.

Amongst the most beautiful of the *Chorozemas* known in cultivation are:—*C. Henchmanni*, with long terminal leafy racemes, of a beautiful red colour, the standard having a green spot at its base; the leaves are awl-shaped, about half an inch long, and generally disposed in clusters of three. *C. spectabile*, a twiner of great beauty, producing long drooping racemes of orange-coloured flowers, which appear in the winter months; its leaves are oblong-lanceolate, with a little point at the apex. *C. cordatum*, a plant very common in gardens, and having ovate short-stalked leaves, heart-shaped at the base, the margins armed with prickly teeth; the flowers, in loose racemes, are red, the standard spotted with yellow at the base. *C. Dicksoni*, a handsome plant with larger flowers than the others; the leaves are entire and lance-shaped, generally having on both surfaces a few long-spreading hairs. There are upwards of fifty species known. [A. A. B.]

**CHOU.** (Fr.)

**CARAIBE.**

*Caladium sagittifolium*, and *Colocasia esculenta*. — **DE CHIEN.** *Mercurialis perennis*. — **FLEUR.** *Brassica oleracea botrytis*. — **MALIN.** *Crambe maritima*. — **PALMISTE.** *Arca oleracea*.

**CHRISTISONIA.** A genus of *Orobanchaceae* containing ten or twelve species, natives of India. They are parasitic plants, with fleshy stems, scattered or imbricated scaly leaves, and the flowers terminal or in the axils of the upper leaves; the calyx is tubular and five-toothed; the corolla infundibuliform and somewhat two-lipped; the anthers two-celled, with one of the cells barren and subulate; and the ovary imperfectly two-celled, the inflexed septa only partially meeting in the axis, and the placentiferous margins remaining free, and being reflexed form two loose placentae in each cell. [W. C.]

**CHRISTMAS ROSE.** *Helleborus niger*.

**CHRISTOPHER, HERB.** *Actaea spicata*; also *Osmunda regalis*.

**CHRISTS EYE.** *Inula Oculus Christi*.

**CHRISTS THORN.** *Paliurus aculeatus*.

**CHRISTYA.** A Cape shrub forming a genus of *Apocynaceae*, and having erect rod-like branches and large handsome flowers, with a calyx divided into five lance-shaped divisions, each with a cleft gland at its base; a somewhat bell-shaped corolla with a row of cleft fleshy scales at its mouth, alternating with the linear divisions of its limb; five anthers, hairy on their back, and cohering with the velvety cushion-like stigma. The two ovaries contain several seeds. [M. T. M.]

**CHROMATIDIUM.** The colouring matter of plants.

**CHROMISM.** Præternatural colouring of plants, as that of leaves when they become red, &c.

**CHROMULE.** The fluid colouring matter of vegetation.

**CHROOLEPUS.** A curious genus of *Algae*, referred to the green-spored division on account of its clear natural affinities, but exhibiting, when fresh, orange not green tints. The species grow on damp walls, rocks, evergreen leaves, bark, &c., and when fresh often emit a scent like that of violets. The minute zoospores are contained in lateral cysts, and by these the genus is at once distinguished from *Callithamnion*, which in some respects it resembles. The black productions, commonly referred to this genus are evidently fungi and not algae. *Chroolepus* sometimes occurs in a rudimentary state on exposed stones, and then obtains the name of the sweet-scented *Byssus*. [M. J. B.]

**CHRYSALOIDEUS.** Rolled up and folded up at the same time.

**CHRYSANTHEME DES INDES OU POMPON.** *Pyrethrum indicum*.

**CHRYSANTHEMUM.** A genus of her-

baceous or slightly shrubby plants belonging to the Corymbiferous group of the order *Compositæ*, distinguished by their hemispherical involucre composed of imbricated scales which are membranous at the edges, large naked receptacles, and by the absence of a pappus from the fruit. The family is represented in Britain by the familiar Ox-eye Daisy, *C. Leucanthemum*, and Corn Marigold, *C. segetum*: the former a common weed in hay-fields, where its flowers, which are white with a yellow disk, are conspicuous; and the latter a handsome but mischievous weed in corn-fields, where it is sometimes so abundant as to be more conspicuous with its large golden-yellow flowers than the crop which it tends to impoverish. Many species have been introduced from various countries, and are cultivated in our gardens, of which *C. grandiflorum* from the Canaries, *C. pinnatifidum* from Madeira, and others, are of a shrubby habit and flower during a large portion of the year, but require protection in winter; while *C. coronarium* from the Levant, and *C. carinatum* (called also *C. tricolor*) from Barbary, are ornamental border annuals. The species, however, which holds so high a rank, and with reason, among florists' flowers is *C. sinense*, a plant which has long been familiar to us from its frequent appearance in Chinese drawings, but has of late years been improved to such an extent as to be prized for its intrinsic beauty, and not simply from its valuable property of blooming in November and December. This plant, popularly known as the Chrysanthemum, is more generally referred by botanists to the genus *Pyrethrum*, as *P. sinense*. Chrysanthemums are classed by growers into Large-flowered, Anemone-flowered, Pompons, and Anemone-flowered Pompons. [O. A. J.]

**CHRYSANTHUS.** Yellow-flowered.

**CHRYSEIR.** A name sometimes given to the species of *ESCHSCHOLTZIA*: which see.

**CHRYSHIPHALA.** A synonym of *Stenomeson*, adopted in some systematic books.

**CHRYSO.** In Greek compounds = golden yellow.

**CHRYSOBACTRON.** A genus of *Liliacæ*, near *Anthericum*, from the Auckland and Campbell Islands, New Zealand. It has linear leaves and racemose flowers (which are occasionally dioecious) of a bright yellow colour. The perianth is six-lobed; the anthers connected (absent in the female flowers). The ovary has three furrows; style thick; stigma capitate, three or six-lobed; capsule ovoid, three-celled, the cells usually two-seeded. *C. Hookeri* is a pretty little bog plant, which has been introduced into this country, where it requires the protection of a greenhouse. [J. T. B.]

**CHRYSOBALANACEÆ.** A family of *Dicotyledons* closely allied to *Rosacæ*, or more generally considered as a tribe of

that order taken in its most extended sense. They are distinguished from the other tribes by a frequent irregularity in the stamens, and more especially by their solitary carpels, with the style always proceeding from the base, and containing two ascending ovules. The fruit is free, either drupaceous or capsular. They are all trees or shrubs with alternate stipulate leaves and several of them produce edible fruits. There are nearly one hundred species, more or less known (including several as yet unpublished), dispersed over the tropical regions both of the Old and New World, although much more abundantly so in the latter. They are distributed into about twelve genera, of which the principal ones are *Chrysoalanus*, *Hirtella*, *Couepia*, *Parinarium* and *Princepia*.

**CHRYSOBALANUS.** This genus, the type of the family to which it belongs, is composed of shrubs and small trees, natives of the tropical parts of Africa and America, one species being found in Florida. It differs from others of the family in having its stamens, in number about twenty, arranged in a regular whorl, not inserted on one side of the flower, as well as in the nut of the fruit being one-celled only. The leaves are alternate, stalked, entire, and obovate in form, having both the surfaces smooth. The flowers, borne in short panicles or racemes, are small, white, and made up of a bell-shaped five-cleft calyx; five petals; about twenty stamens; and an ovary the style of which arises from one of its sides near the base, which latter is one of the principal characters of the family. The *Coccolapium*, *C. loaco*, is one of the commonest species. The fruits are about the size of a plum, and vary much in colour, being either white, yellow, red, or purple. The pulp is sweet, a little austere, and not disagreeable. The shell of the kernel is hard and six-grooved. In the West Indies, according to McFadyen, the fruits prepared with sugar form a favourite conserve with the Spanish colonists, and large quantities are annually exported from Cuba. The kernels yield a fixed oil, and an emulsion made with them is said to be used in dysentery. An astringent bath recommended in leucorrhœa and blennorrhœa is prepared from the leaves and roots. Four species are known. [A. A. B.]

**CHRYSOCHROUS.** Having a yellow skin.

**CHRYSOOMA.** A genus of South African shrubs or undershrubs of the *Compositæ* family, nearly allied to *Linocyprie*, from which it differs in the hairs of its pappus being in a single series. About nine species are enumerated. Their leaves in most cases are linear in form and entire. The yellow nearly spherical flower-heads are about the size of a pea, and single on the ends of the branches; the florets all tubular and perfect. The achenes are laterally compressed, somewhat hispid, and seated on a naked honey-combed

receptacle. *C. Coma aurea* is in cultivation, and is said to be a very common species about Cape Town; its leaves are linear, and about half an inch long. [A. A. B.]

**CHRYSOORYNE.** A curious genus of small annual Australian plants belonging to the Compositae family. They are branched from the base, and seldom exceed three inches in height. The leaves are small, linear, and covered with loose white wool; but the most marked feature in the plants is the arrangement of the flower-heads: these are disposed in short yellow club-shaped spikes, and each flower head is almost hidden by a yellow bract, and contains but two florets. The florets are tubular and bi- or tridentate, an unusual circumstance in this family. The achenes are covered with wart-like glands, and are destitute of pappus. Five species are known; they are chiefly found in the western and southern parts of Australia. [A. A. B.]

**CHRYSOOCYNIS** *Schlimtli* is a New Grenada epiphytal Orchid, with a thick creeping rhizome, from which arise at long intervals small flat pseudo-bulbs, each bearing one stalked oblong leathery leaf. From the base of the pseudo-bulbs rise numerous short one-flowered peduncles clustered in the manner of some *Maxillarias*. The flowers are furnished with a sagittate stalked lip, and are rose-coloured or dull purple, by no means yellow, as shown in Reichenbach's *Xenia*, t. 55, and as the name implies. The genus, if it be one, is near *Oamaridium*.

**CHRYSODIUM.** A synonyme of the typical species of *Acrostichum*, represented by *A. aureum*. [T. M.]

**CHRYSOGLOSSUM.** Under this name Blume has a genus of two species only, *C. ornatum* and *villosum*, inhabiting the mountainous parts of Java. Both are terrestrial one-leaved Orchids, allied to *Liparis*, and have fleshy subterranean rhizomes. In *C. villosum*, a shaggy plant, and the best known of the two species, the leaf is large, plaited and ovate, while the scape is about two feet high, bearing orange and yellow flowers the size of a wild pansy.

**CHRYSOGONUM.** This genus of the Composite family differs from its allies in its achenes being crowned with a two or three-toothed pappus. Its only representative is *C. virginianum*, a dwarf perennial herb found in many parts of the United States. All its parts when young are covered with hairy tomentum. It is nearly stemless when it begins to flower, but soon sends out several stems, some of which are erect and flower-bearing, while others take the form of runners and creep along the ground. The leaves are opposite on long stalks, ovate, with notched margins. The flower-heads, stalked, solitary, and terminating the branches, are made up of numerous bright yellow florets, those of the ray few and strap-

shaped, and those of the disc numerous and tubular. [A. A. B.]

**CHRYSOMA.** A genus of North American plants of the Composite family, considered by the authors of the *Flora of North America* to be the same as that of the golden rod (*Solidago*). The species are perennial plants, with alternate lance-shaped entire or serrated leaves, sometimes furnished with pellucid dots, and they bear terminal corymbs of yellow flower-heads, each of which contains from six to eight florets, one to three of them being strap-shaped. [A. A. B.]

**CHRYSOPHYLLUM.** A name expressive of the golden colour on the underside of their leaves, which the trees of this genus possess. It is a group of *Sapotaceae*, and consists of trees with a milky juice, alternate leaves with numerous transverse closely aggregated ribs, and golden hairs on the under surface. The corolla is somewhat campanulate; its tube bears five fertile stamens and no sterile ones; the ovary is five to ten-celled with a short style; the fruit is a berry with ten cells, or one only from the suppression of the rest. Some of the species are grown in this country for the sake of their handsome foliage; while in the West Indies the fruit of *C. Caimito* is esteemed a delicacy under the name of the Star apple, inasmuch as it is of the size of a large apple, while the interior, when cut across, reveals ten cells, and as many seeds disposed regularly around the centre. [M. T. M.]

**CHRYSOPSIS.** A genus of annual or perennial North American plants of the Composite family, the greater portion of the species having all their parts covered with villous or silky hairs. The oblong or linear leaves are usually entire and sessile. The showy yellow flower-heads, usually terminating the branches and often corymbose, have an involucre of many linear scales enclosing numerous florets: those of the ray strap-shaped and bearing pistil only, those of the disc tubular and perfect. The genus differs from its allies in having the pappus of the ray and disc florets similar and double, the exterior short and scale-like, the inner copious and capillary. *C. villosa*, a plant with oblong hairy leaves about an inch and a half long, and numerous yellow flower-heads, half an inch in diameter, is said to be one of the commonest plants on the prairies of the Saskatchewan. *C. graminifolia* extends southwards to Mexico; its leaves are clad with beautiful close-pressed silvery hairs. [A. A. B.]

**CHRYSOPTERIS.** A synonym of *Phlebodium*, a genus of Ferns which includes Linnaeus's *Polypodium aureum*, the specific appellation seeming to have suggested this generic name. [T. M.]

**CHRYSORRHÖE.** A genus of *Chamaelacaceae*, consisting of a rigid shrub from the Swan river, with narrow terete leaves, and terminal corymbs of bright yellow

flowers. The sepals are five in number, and cut into many pilose segments; the petals five, serrate; the stamens free, ten fertile and ten imperfect and shorter than the others; the ovary completely covered by the disc. The genus is closely allied to *Verticordia*, but that has monadelphous stamens, and the sterile ones longer than the fertile. [J. T. S.]

**CHRYSOSPLENIUM.** Golden Saxifrage. A small genus of unimportant herbaceous plants belonging to the *Saxifragaceae*, among which they are discriminated by their one-celled seed-vessel, and by being destitute of petals. Two species are indigenous to Britain, and scarcely differ from one another, except that one has the leaves opposite, the other alternate. They grow on the margins of streams, forming extensive patches, and in hilly districts often betray, by a line of bright green, the course of a mountain-spring which has worn a narrow way for itself down the slope. The roots are intermatted and send up numerous delicate green very succulent stems, to the height of three or four inches. The leaves are roundish, somewhat fleshy, and sprinkled with longish hairs. The flowers, which are bright yellowish-green, appear in April and May, growing in fat tufts at the summit of the stems. *C. oppositifolium* is the commonest species. *C. alternifolium* is more abundant in the north. The genus is represented in various parts of the world by plants of similar habit, none of which are worthy of cultivation. In the Vosges, the species are used as a salad under the name of *Cresson de Roche*; French, *Dorine*; German, *Goldmiltz*. [O. A. J.]

**CHRYSOSTEMMA.** Under the name of *C. tripteris* is sometimes cultivated in gardens a tall smooth North American herb of the Composite family, with opposite leaves, those on the lower part of the stem pinnately five-parted, the upper ones three-parted, with lance-shaped segments one to four inches long, and having the yellow-rayed flower-heads arranged in a corymbose manner at the ends of the twigs, each head one to two inches across. The plant is placed by modern authors in the genus *Coreopsis*, with the same specific name, and may be recognised from others in that genus by the achenes being narrowly-winged, with a toothed fringe at the summit of the wing. [A. A. B.]

**CHRYSOXYLON.** The name of a South Bolivian tree, now referred to *HOWARDIA*, which see. It derived its name from the yellow colour of its wood.

**CHRYSURUS.** A genus of grasses belonging to the tribe *Festuceae*. Only one species is described, *C. cynosuroides*, which is the *Lamarckia aurea* of some authors. This handsome dwarf-habited annual grass is a native of the south of Europe and north of Africa, and is occasionally cultivated in gardens. [D. M.]

**CHUCHU.** The Chocho, *Sesuvium edule*.

**CHUICHUNCHULLI.** The root of *Lontidium microphyllum*.

**CHU LAN.** The flowers of *Chloranthus inconspicuus* and *Aglaia odorata*, used in China to scent tea.

**CHUMBELEE.** *Jasminum grandiflorum*.

**CHURN-STAFF.** *Euphorbia helioscopia*.

**CHURRAS.** The Nepalese name of the resinous exudation of the Hemp, *Cannabis sativa*.

**CHUSSALONGO.** The vulnerary, Matico, *Eupatorium glutinosum*.

**CHYMOCARPUS.** A genus of scandent herbs belonging to the *Tropaeolaceae*. The flowers consist of a coloured calyx, prolonged behind into a hollow spur, and divided at the margin, in a somewhat two-lipped manner, into five nearly equal lobes; a corolla of two petals inserted in the mouth of the tube-like spur; and eight hypogynous stamens. The sessile three-lobed three-celled ovary grows into a three-lobed sweet fleshy edible berry, which remains attached to the front of the persistent calyx. This black juicy berry, which is not unlike in appearance and flavour to the Zante or currant grape, is the most remarkable peculiarity of the genus, which was founded on *C. pentaphyllus*, a plant of Bucoene Ayres, long cultivated in our gardens. This is a handsome species, with a thick fleshy fusiform tuber, and smooth filiform stems, climbing several feet high, and furnished with alternate stalked five-parted leaves, having oblong-elliptic leaflets. The flowers are solitary in the axils of the leaves, the spur of the calyx funnel-shaped, above an inch long, bright orange-red, the limb green, marked with dark red spots. The two petals are very small, purple. [T. M.]

**CHYSIS.** Under this name are collected about four species of Orchids from tropical America, with fleshy stems covered with sheaths, thin-ribbed leaves, and lateral spikes of large handsome white or yellow flowers of the consistence of wax. The finest species is *Chysis bracteacea*. They all have eight pollen masses attached to a broad yellow pulverulent somewhat rectangular plate.

**CIBOTIUM.** A genus of polypodiaceous Ferns, belonging to the *Dicksoniae*, among which it is distinguished by having the indusia or involucre two-valved, both the valves being coriaceous, the outer one larger and cucullate, the inner one operculiform. They are large growing and very handsome ferns, in some cases arborescent, the fronds bipinnate and often glaucous beneath. The fructification is remarkably pretty. *C. Barometz*, sometimes called *C. glaucescens*, is believed to be the Baranets, *Agnus Scythicus*, or Tartarian Lamb, about which travellers have told so wondrous a tale. This 'Lamb' consists merely of the decumbent shaggy caudex of a kind of

fern, which is no doubt the species just referred to. When inverted, the basal part of the stipes of four of the fronds suitably placed, having been retained as legs, and the rest cast away, these caudices present an appearance which may be taken as a rude representation of some small woolly animal. The 'traveller's tale' is that on an elevated uncultivated salt-plain of vast extent, west of the Volga, grows a wonderful plant, with the appearance of a lamb (Baran in Russian), having feet, head, and tail distinctly formed, and its skin covered with soft down. The 'lamb' grows upon a stalk about three feet high, the part by which it is sustained being a kind of navel; it turns about and bends to the herbage, which serves for its food, and pines away when the grass dries up and falls. The fact on which this tale is based appears to be, that the caudex of this plant may be made to present a rude appearance of an animal covered with silky hair-like scales, and if cut into is found to have a soft inside with a reddish flesh-coloured appearance. When the herbage of its native haunts falls through drought, its leaves no doubt droop and die, but both perish from the same cause, and independently of each other. 'Thus it is,' observes Dr. Lindley, that 'simple people have been persuaded that there existed, in the deserts of Scythia, creatures half animal, half plant.' 'This condition of the rootstock of some ferns,' writes Sir W. J. Hooker, 'long engaged the attention of early writers of the marvellous, and many strange figures were published of it; but Dr. Beyne, of Dantzic, in 1795, declared that the pretended *Agnus Scythicus* was nothing more than the root of a large fern covered with its natural villus or yellow down, and accompanied by some of the stems, &c., in order, when placed in an inverted position, the better to represent the appearance of the legs and horns of a quadruped.' He also adds, 'that the down or villus is the *poco sempic*, or "golden moss," so much esteemed by the Chinese for the purpose of stopping hæmorrhage,'—the very use to which it has been found to be applied elsewhere in modern times. A substance called Pulu, consisting of silky fibrous hairs, used for stuffing mattresses, &c., is obtained from three species of this genus, *C. glaucum*, *Chamissoi*, and *Menziesii*, natives of the Sandwich Islands, whence this article has become a regular export, to the extent of some thousands of pounds annually. This Pulu consists of the hair-like scales found on the crown of the stem and about the base of the frond-stalks of the ferns; only a small quantity, about two or three ounces, is found on each plant, and it takes about four years for the plants to reproduce this amount. The ferns which produce the Pulu grow on all the high lands of the Sandwich Islands at an elevation of about 1000 ft. The silken golden-coloured hairs of *Dicksonia Oulella* are employed in the same way in Madeira and the adjacent isles. A similar fibrous substance, used

medicinally as a styptic, is derived in the islands of the Eastern Archipelago from the caudex and stipes of *C. Barometis*; and also from *Dicksonia chrysotricha*, of which latter a plantation belonging to the Dutch government exists in the interior of Java, and the produce of this plantation has been exported to Holland for public sale. This substance is called Penghiawar Djambi. Its styptic properties seem attributable to

*Clibotium Barometis* (caudex, in a natural state, and formed into a Tartarian Lamb)

the rapidity with which its filaments, acting by capillary attraction, absorb the aqueous particles of the blood, and thus cause its immediate coagulation. *C. Menziesii*, one of the species said to furnish Pulu, has large thick coriaceous bipinnate fronds, the large oblong acuminate sinuato-plumatifid pinnules with rounded lobes, bearing several large coriaceous opaque involucre. This may be taken as a fair representative of the other species, one of which, besides those already mentioned, is found in Assam, and another of very graceful habit in Mexico. [T. M.]

**CIBOULE.** (Fr.) *Allium ascalonicum*. — **COMMUNE.** The Welsh Onion, *Allium fistulosum*.

**CIBOULETTE.** (Fr.) *Allium Schoenoprasum*.

**CICATRICULE.** The scar formed by the separation of a leaf from its stem.

**CICATRISATE, CICATRICOSE.** Marked with scars.

**CICATRIX.** Any kind of scar formed by the separation of one part from another.

**CICCOA.** A genus of *Euphorbiaceæ*, comprising a number of small trees or shrubs, natives of the tropical parts of India, Africa, and America. The leaves, stalked, entire, and generally oval, are furnished with minute stipules; the small green flowers are shortly stalked, generally four to five in the axils of the leaves, but sometimes in long-bracted racemes; the males and females being on the same, or on different plants. The males have a calyx of four divisions, no petals, and four free stamens inserted on a disc, which arrangement of the parts in fours serves to distin-

guish the genus from its allies. The calyx of the females is like that of the male. The ovary is three or five-celled, crowned with a like number of styles, each divided at the apex in the form of a V, and each cell contains two seeds. *C. disticha*, sometimes called the Otaheite Gooseberry, is an elegant small tree and a native of India, where it is cultivated, as well as in many other countries, for the sake of its fruits. The slender leaf-bearing branches, about a foot long, are furnished with numerous oval smooth leaves, and might by a superficial observer be taken for pinnate leaves. The racemes of small flowers proceed from the old wood, and are provided with a number of small scales, each of which bears in its axil six to eight stalked flowers. The fruits in size like those of a gooseberry are green, three or five-furrowed, and somewhat acid and cooling. In India they are used as an article of food, either in a raw state or cooked in various ways. Europeans pickle or make preserves of them, and also use them in tarts. In Java they are brought to the markets and sold for preserving at threepence per gallon. A decoction of the leaves is used to cause perspiration, and the roots are emetic, but too violently so to be used.

*C. indica*, sometimes called *Prosorus indicus*, is a tree of thirty or forty feet high, found in the Bombay district and also in Ceylon; its ovate-lanceolate entire leaves are pale green underneath, and the flowers are in axillary fascicles. The bright blue seeds are contained in a dry capsule, and according to Mr. Thwaites are a favourite food of the green pigeon. Its wood is white, tough, and used for building purposes in Ceylon. [A. A. B.]

**CICELY, SWEET.** *Myrrhis odorata*; also an American name for *Osmorrhiza*.

**CICER.** A genus of Leguminous plants, which, in combination with five or six others, closely allied, forms the vetch tribe of that order. About a dozen or fifteen species, natives of Southern or Eastern Europe, Western Asia, and Abyssinia, are described. They are annuals or perennial herbaceous plants or undershrubs, clothed with glandular hairs, and having pinnate leaves, consisting either of a definite number of leaflets in pairs with the leaf-stalk terminating in a tendril, or of several pairs of leaflets with an odd one at the end, the leaflets being conspicuously marked by veins. The generic character consists in the tube of the five-lobed calyx being puffed out on the upper side, and two or three of the lobes being pressed upon the upper petal of the pea-like corolla. The pods have their sides swollen out, and contain only a few (seldom more than two or three) seeds, which bear some resemblance to peas, but are of an irregular shape.

*C. arvense* is the Chick-pea, or Egyptian pea of the English, the 'Ceca' of the Italians, the 'Gartbanas' of the Spaniards, and the 'Gram' of India. It is an annual plant, growing about a foot or more in

height, and is a native of the south of Europe, and also of India. Its leaves consist of from three to seven pairs of leaflets with an odd one at the end, the leaflets being egg-shaped, and having their edges cut into very sharp teeth. Both leaves and stems are covered with glandular hairs containing oxalic acid, which exudes from them in hot weather and hangs in drops, ultimately forming crystals. The flowers are either white or rose-coloured, and are produced singly upon stalks growing from the bases of the leaves. The pods are from an inch to an inch and a half long, of a rhomboidal form, with puffed-out sides, and generally contain two seeds, but sometimes only one. These seeds vary in size and colour in different varieties, the finest kinds being nearly a quarter of an inch in diameter, slightly pointed, and of a pale-yellow colour, with their skins netted in consequence of inward shrivelling, and having two swellings on one side; the peculiar form of these peas has given rise to the specific name of the plant *aristinum*, which alludes to their supposed resemblance to a ram's head.

This plant is extensively cultivated in India and other eastern countries, and likewise in the south of Europe. In India the seeds form one of the pulses known under the name of 'Gram,' and are greatly used as an article of food by the natives, being ground into meal, and either eaten in puddings or made into cakes. They are also toasted or parched, and in this state are commonly carried for food on long journeys; rolled in sugar-candy, these toasted peas form a rough sort of comfits, and gram-flour made up with sesamum oil and sugar-candy is an Indian sweet-meat. Small quantities of these peas come to this country from Turkey, and are used for grinding into pea-meal. Attempts have been made to employ them as a substitute for coffee. In Paris they are greatly used in soups. [A. B.]

In Mysore the natives collect the dew from the 'Gram' plants by means of muslin cloths, which become saturated with it. The liquid thus obtained, which is very acid, is ----- in bottles for use, and is regarded as a sure medicine in cases of indigestion, being administered in water. It is stated that the boots of a person walking through a dewy gram field will be entirely destroyed by the pungency of this acid given out by the leaves. [T. M.]

**CICER.** (Fr.) *Astragalus Cicer*; also *Cicer aristinum*.

**CICORACEÆ.** (Chicory family.) A sub-order of the natural order *Compositæ* or *Asteraceæ*, under which its full characters are given. The plants have numerous florets (small flowers) on a common head, and all of them are irregular, having a ligulate form in consequence of the corolline tube being split down on one side, and a tongue or strap-like process formed by the united petals projecting on the other side. The suborder sometimes receives the name of *Ligulifloræ* from the form of the

flowers. The stamens are united, and their anthers are as other syngenesious or composite plants. The fruit is an achene adherent to the calycine-tube, and furnished with pappus or a hairy calycine limb at the top. The plants abound in a milky juice, and they have bitter and sometimes narcotic qualities. Some of them, as the Dandelion, act on the kidneys and the liver. Some of them are esculent vegetables and salads. They abound in cold regions. Their heads of flowers have usually the property of opening under the influence of light and closing in darkness. Chicory or Wild Succory (*Cichorium Intybus*) is much cultivated in France and Germany, its roots being used as an addition to coffee. The admixture, without the due indication of it, is forbidden in Britain. *Cichorium Endivia* supplies the salad called endive. *Lactuca virosa* furnished *Lactucarium*, a drug employed in place of opium to procure sleep. Common Lettuce is the produce of *Lactuca sativa*. *Scorzonera* is the root of *Scorzonera hispanica*, while Salsify is obtained from *Fragopogon porrifolius*. The root of Dandelion (*Leontodon Taraxacum*) is sometimes used as coffee. See **ASTERACEÆ**. [J. H. B.]

**CICHOBIUM.** A genus of Compositæ which includes the Chicory and the Endive, and belongs to the division characterised by the presence of ligulate or strap-shaped florets only in the heads of flowers, and by the presence of a milky juice. It consists of perennial plants, with stiff branching stems, and sessile heads of blue flowers, surrounded by an involucre consisting of two rows of bracts, the outer of which are reflexed and shorter than the inner. The fruits are crowned by two rows of minute scales, constituting the limb of the calyx.

The Wild Chicory or Succory, *C. Intybus*, is a perennial plant found in this country by roadsides and in dry, especially chalky, soil. It has a long tap root, and a rigid slightly hairy branched stem, with a few sessile clasping leaves. The lower leaves spread on the ground, and are pinnately lobed and coarsely toothed, while the upper ones are scanty and embrace the stem by the two pointed lobes at their base. The heads of flowers are few, sessile, of the size of a penny-piece, and of a brilliant light blue colour. The leaves of chicory are blanched and used as a salad under the name of Barbo du Capucine. The root roasted was largely used to mix with and adulterate coffee, but within the last few years grocers mixing chicory with coffee are bound to affix a label on the outside of the package announcing the admixture, so that purchasers can now have pure coffee, or coffee mixed with chicory, as they prefer—for there are some who like the mixture. It need hardly be said that chicory is entirely destitute of those properties which render coffee an agreeable and nutritive beverage, while on the other hand it possesses medicinal properties closely like those of dandelion, and which therefore render it unwholesome for

constant use. Moreover, the chicory used to mix with coffee is very often largely

detection of these several materials is easily accomplished by the aid of the microscope and the test tube as shown in Dr. Hassall's work on the adulteration of food. Chicory is readily cultivated in this country. That grown at Canterbury was acknowledged to be finer than that imported from abroad, and would have been a very profitable crop, but that the buyers arbitrarily fixed a lower price upon the English than upon the imported. The herbage forms good food for cattle. [M. T. M.]

The Endive, *C. Endivia*, is a hardy annual indigenous to the northern provinces of China, and other parts of Asia, and, according to the *Hortus Kewensis*, was cultivated in this country in 1548. Macintosh in his *Book of the Garden*, believes it is also a native of Egypt, and that it was carried from thence to Italy, and afterwards into Britain. Be this as it may, there is no doubt of its having been used as an esculent from a very early period by the Egyptians, who probably communicated it to the ancient Greeks and Romans, along with their manner of using it. Endive, radishes, and succory are mentioned by Ovid as forming part of a garden salad; and Pliny states that endive in his time was eaten both as a salad and potherb. As such it has been used in this country for three centuries, and it is a singular fact that the manner in which it was prepared for winter use, as described by Gerard in 1597, differs but little from the mode that is often practised at the present day. The plant has numerous large sinuate smooth toothed, or in some varieties much undulated and finely-curved deep-green leaves. The flower-stem rises about two feet high and produces numerous pale-blue flowers. It is cultivated solely for the stocky head of leaves, which after being blanched to diminish their bitterness, are used in salads and stews during winter and spring. The different varieties of endive are arranged in two classes, namely: 1, the *Batavian* (Scaroles of the French), which comprises all with large broad leaves, slightly ragged or torn; and 2, the *Curled* or *Chicorees* of the French, being all those with crisp and finely-frizzled leaves. [W. B. B.]

**CICORIUM.** A section of the genus *Pelargonium*, comprising the species with the petals all the same colour, the two upper ones shorter and narrower than the rest; stamens short and erect, the two lowest shorter, with the anthers nearly sessile. The stems are somewhat shrubby and fleshy. [J. T. B.]

**CICUTA.** A deadly genus of Umbellifera or *Aplacæ*, known by their dissected leaves, by their compound umbels without any general involucre, but with partial involucre consisting of several awl-shaped bracts, and by the teeth of the calyx pro-

jecting above the fruit, which is roundish, compressed at the side, and marked with ten scarcely prominent ridges, five to each half of the fruit, while beneath each furrow in the rind of the fruit there runs a single channel filled with volatile oil.

*C. virosa*, the Cowbane or Water Hemlock, is a plant occasionally found wild in this country by the side of ponds and ditches. The rootstock is large, white, and fleshy, covered externally with fibres, and internally hollow and divided into several compartments, by transverse partitions, filled with a yellowish milky juice. The stem is erect, hollow, striated, somewhat branched, and attains a height of three or four feet. The leaves are twice or thrice-plumate, with narrow lance-shaped segments, one to one and a half inches long, and slightly toothed at the margin. The umbel consists of from ten to fifteen principal rays, unprovided with any involucre or with only a few small bracts. The flowers are whitish. This plant is dangerously poisonous, having qualities like those of *Conium*; indeed, it is called Water Hemlock. It produces tetanic convulsions, and is fatal to cattle eating the herbage. In April 1857, two farmer's sons were found lying paralysed and speechless close to a ditch where they had been working. Assistance was soon rendered but the poor fellows shortly expired.

*Cicutaria virosa*.

A quantity of the Water Hemlock grew in the ditch where they had been employed. A piece of the root was subsequently found with the marks of teeth in it, near to where the men lay, and another piece of the same root was discovered in the pocket of one of them, so that there can be no doubt that they were poisoned by eating the root of this plant in mistake for some other. The root of the American *C. maculata* is even more virulent. [M. T. M.]

CICUTAIRE. (Fr.) *Cicuta*.

CIERGE. (Fr.) *Oreus*.

CIGUE AQUATIQUE. (Fr.) *Cicuta virosa*. — D'EAU. *Gnaphtho Phellandrium*.

— GRANDE. *Conium maculatum*.  
— PETITE. *Athusa Cynapium*.

CILIX (adj. CILIATED). Marginal hairs forming a fringe.

CILIATO-DENTATE. When the teeth of anything are finely serrated as if fringed.

CILIATO-SERRATE. When the serratures of anything end in a hair.

CIMICIFUGA. Bugbane. A genus of *Ranunculaceae*, allied to *Actaea*, but differing by having several carpels, which are follicles, not berries. The species are natives of Eastern Europe, Siberia, and North America.

The European species, *C. foetida*, which has twice-ternate leaves and racemes of inconspicuous flowers arranged in a terminal panicle, is extremely foetid, and has been used to drive away vermin, whence the generic name. [J. T. S.]

CIMICINE. Smelling of bugs, as *Cortander*.

CINCHONA. This important genus gives its name to the order of which it is a member. The genus consists of evergreen trees or shrubs growing in the tropical valleys of the Andes. The flowers are of a white or pinkish colour, very fragrant, arranged in panicles. The corolla is salver-shaped, and nearly, if not quite, conceals the five stamens. The ovary is crowned with a fleshy disc; the style is simple; the stigma two-lobed. The fruit is an ovate capsule, grooved on both sides, crowned by the limb of the calyx, and dividing from below upwards, in order to allow of the escape of the numerous winged seeds.

There are, according to Weddell, numerous species of this genus, but only some of them yield the commercial Cinchona, or Peruvian bark. Of this there are several varieties, the most esteemed of which are the Calisaya or yellow bark, the produce of *C. Calisaya*; grey, or Huanuco bark, the produce of *C. micrantha* and *C. nitida*; Loxa, or crown bark, the produce of *C. Condaminensis* (*officinalis*); and red bark, furnished by *C. succubra*. Their great value as tonics and remedies for fevers, depends upon the presence of certain alkaloid substances called *quina*, *quinidine*, *cinchonine*, and *cinchonidine*, which exist principally in the cellular tissue outside the liber, in combination with kinetic and tonic acids. It is found that certain of the barks contain more of one principle than of another; hence their greater or less value commercially, and the skill and complex knowledge required by the manufacturer to distinguish the different varieties of bark one from the other. *Quina* is the most useful of the alkaloids, and this is found in greatest abundance in Calisaya bark; *cinchonine* occurs most abundantly in the best grey and red barks; while Loxa bark furnishes the largest amount of *quinidine*. The several alkaloids have all similar properties, but varying in degree. Quina, in its combination with sulphuric acid, is the most gener-

VEGETATION OF THE CINCHONA FORESTS OF PERU, WITH PALMS & TREE-FERNS  
(After Weddell)

ally used under the name of sulphate of quinine—next to opium and calomel, probably the most important of all drugs. The alkaloids extracted from the barks are recognised by their distinctive chemical characteristics, while the barks producing them are likewise distinguished by a careful scrutiny of their external appearance, the lichens, &c., growing on them, the way in which they break, their taste, odour, &c., as well as by their microscopical and chemical characteristics. The way in which the barks break, or the fracture, as it is termed, depends on their anatomical structure, that is to say, on the size and arrangement of their cellular and woody portions. Where the former preponderates, the fracture is smooth and even, and such barks are said to yield the greatest quantity of quinine. Where there is less cellular tissue, or the constituent cells are smaller, then a fibrous or stringy fracture is observable, and a short stringy fibrous fracture is considered to be an indication of the presence of quinine. No doubt the same tree, in varying circumstances, produces different sorts of bark; while similar-looking barks may be produced by very different species.

The *Cinchona* trees grow in the forests of Bolivia, Peru, &c., in groups or clusters. The cascarrilleros, or bark collectors, encamp in these forests, and ascertain where the trees are to be found, a process in which the sagacity and endurance of the Indians are put to a severe test. They are reported to be able to tell the trees at a distance by a peculiar movement of the leaves, and by the colour of the masses of bloom. When the position of the trees has been ascertained, there is frequently much difficulty in getting to the spot; this done, however, the trees are felled; no light labour, for the intertwining climbing plants sustain the trunks when cut through. When the trees are at length felled, the bark is stripped off all round, and cut into pieces of a convenient size for carriage; and particular care is taken to secure the bark near the root, as it is there thicker and more valuable. The bark from the small branches rolls up when stripped into cylindrical pieces or quills, while the larger pieces are placed in stacks to dry, with a heavy weight on the top. The carriage of the packages of the bark to the place of encampment by a route which is traversed with much difficulty by the unembarrassed Indian, is a work of great hardship and labour.

In the process above described, the trees are necessarily destroyed, and hence the supply of this valuable drug was in imminent danger of exhaustion. Thanks, however, to the labours of Messrs Markham, Spruce, and others in South America, as well as to those of Mr. McIvor and other cultivators in India, there are now established in many of the hilly districts of the latter country large plantations of the most valuable kinds of cinchona, the commercial success of which seems assured. Mr. Wilson also has met with tolerable success in the cultivation of

these plants on the higher mountains of Jamaica.

The species most cultivated in India are *C. succotrubra*, and *C. officinalis*, and it is found not only that the tree will thrive, but that the quantity of alkaloid is as great as in the South American barks. Moreover, by the process of 'mossing,' introduced by Mr. McIvor, and which consists simply in protecting the bark from light and air by a layer of damp moss, the quantity of alkaloid can be increased. The mossing process also allows of the periodical removal of the bark, and it is found that the new layers formed after the removal of the old bark are even richer in alkaloid than are those first formed.

Bark was first employed in Europe in the middle of the seventeenth century. The discovery of its medicinal value is a matter of fable and conjecture. The name *Cinchona* is derived from the wife of a Viceroy of Peru, who is said to have brought the drug from South Ame-

*Cinchona Calisaya.*

rica in 1639. Afterwards the Jesuits used it; and it became generally known when Louis XIV. purchased of Sir R. Talbor, an Englishman, his heretofore secret remedy for the cure of intermittent fever, and made it public. For full information on the subject of *Cinchona* and its barks, the reader should consult the magnificent works of Weddell and Howard, the account of Mr. Markham's travels, Mr. Spruce's report of his explorations, or the valuable epitome contained in Pereira's *Materia Medica*, from which sources the greater part of this notice has been gleaned. The aspect of a *Cinchona* forest is shown in Plate 12. The name is now sometimes written *Chinchona*. [M. T. M.]

**CINCHONACEÆ.** (*Rubiaceæ*, *Cinchonads*, the Peruvian bark family.) A natural order of gamopetalous Calycifloral Dicotyledons, characterising Lindley's Cinchonol alliance. The order is sometimes considered as a sub-order of the natural family of *Rubiaceæ*, or Madderworts. Trees, shrubs,

er herbs, with simple opposite leaves, having glandular stipules placed between the bases of the leafstalks (interpeticular), and flowers arranged in panicles or corymba. Calyx adherent, entire, or toothed; corolla regular; stamens attached to the corolla. Ovary two-celled; style one. Fruit inferior, either dry or succulent, splitting into two or not opening; seeds either definite in number, or numerous, containing a small embryo in horny albumen. Chiefly found in tropical regions, where they constitute  $\frac{1}{2}$  of the flowering plants. In northern regions the order is represented by *Guttiferae*, which some regard as a sub-order of *Eubiaceae*. The order furnishes many important products. The plants supply remedies for intermittent fevers: some are emetics and purgatives, others act in strengthening the tone of the stomach. The various medicinal barks are yielded by species of *Cinchona*, which grow in the Andes between 2,000 and 9,000 feet of elevation above the level of the sea. *Coffea arabica* supplies Coffee, which is the hard albumen of the seeds. *Cephaelis Ipecacuanha* yields the well-known Ipecacuan root which is used commonly as an emetic. A dye called Soorange is procured from the root of *Morinda coccifolia*. White Gambier, a kind of catechu, is the product of *Uncaria Gambir*. Gardenias have showy as well as fragrant flowers, and *G. Rothmannia* yields an edible fruit. There are upwards of 300 genera and 2,600 species in the order. Illustrative genera: *Spermacoce*, *Cephaelis*, *Coffea*, *Isora*, *Hedyotis*, *Pentas*, *Cinchona*, *Nauclea*, *Gardenia*, *Mussaenda*. [J. H. B.]

**CINCINALIS.** This name as originally employed by Gleditsch is a synonyme of *Pteris aquilina*; as however used by subsequent writers it is synonymous with *Pteris*, a genus of Ferns. [T. M.]

**CINCLIDIUM.** A fine genus of Acrocarpous Mosses belonging to *Sryaceae*, and closely allied to *Mnium*, agreeing with it in the characters of the stem and large leaves, but differing in having the inner peristome cup-shaped with sixteen short outer teeth. It occurs in spongy bogs and is rare in Great Britain. It resembles in general appearance *Mnium punctatum*, but the stems are more densely matted together with the purple rootlets. Only one other species is known, *C. arcticum*, which has been found in Norway. [M. J. B.]

**CINCLIDOTUS.** A genus of aquatic Acrocarpous Mosses belonging partly to that division which has been called *Cladocrypt*, because in the majority of species the fruit terminates in short lateral branches. It is named from the lattice-like structure of the peristome, which consists of thirty-two teeth anastomosing at the base. This structure obtains in *C. fontinaloides*, which grows in large tufts on rocks and stones in rivulets and on the borders of lakes, especially in hilly limestone districts, and also in *C. riparius*;

but in *C. aquaticus* the peristome is quite rudimentary. [M. J. B.]

**CINCOTUS.** A term applied to albumen when surrounded by an annular embryo.

**CINENCHYMA.** That kind of tissue in which latex, or the proper juice of plants, is supposed by some to be conveyed from place to place. Probably a form of the intercellular passages.

**CINERACEOUS.** Ash-greyish.

**CINERAIRE.** A' FLEURS BLEUES. (Fr.) *Agalthea amelloides*.

**CINERARIA.** A family of Compound flowers, difficult of discrimination, and containing many species which are referred by some botanists to the genus *Senecio*, &c. As at present constituted, *Cineraria* does not contain any native examples, but is well known as an ornament of the conservatory and window garden. Some of the species are half-shrubby, but the majority are herbaceous and of easy cultivation; and some may be so managed as to be made to bloom almost at any season. *C. cruenta*, a native of Teneriffe, has heart-shaped leaves, variously toothed at the edge, tinged with red or purple, or of unmixed green; the upper leaves clasp the stem and are auricled at the base. In the wild state of the plant, the flowers have a deep purple disk with bright purple rays; but since it has been taken up as a florist's flower, a countless number of varieties have been raised from seed, with flowers in which white, purple, rose-colour, crimson, violet, azure, &c., are combined in ever-varying proportions. 'The early flowering of this plant,' says *Le bon jardiner*, 'its long duration, which allows it to be an ornament of the conservatory and window during several months, have given some importance to its culture.' [C. A. J.]

**CINEREOUS.** 'Ash-grey; a mixture of white and black.

**CINNABAR, CINNABARINOUS.** Scarlet touched with orange.

**CINNAMODENDRON.** A genus allied to *Cassia*, and like it belonging to *Cassiacae*, but distinguished by its petaliferous flowers, and lateral inflorescence. The *C. zillare* is a Brazilian tree, with smooth whitish bark cracking transversely. Its leaves are alternate, leathery, elliptic, and entire; its peduncles axillary, three-flowered. The flowers have three bracts, four (or five) sepals, and as many petals (petaloid scales), with hypogynous stamens, united by their filaments into a tube. The bark is aromatic, and used as a tonic and antiscorbutic. [J. T. S.]

**CINNAMOMEUS.** The colour of cinnamon.

**CINNAMOMUM.** The trees furnishing Cinnamon and Cassia barks belong to a genus of  *Lauraceae*, or true laurals, characterized by the presence of ribbed leaves, leaf-buds not provided with scales, a six-

clef leathery calyx, nine fertile stamens in three rows, with four-celled anthers which open inwardly, except those of the third or innermost row, which open towards the outside of the flower. The stamens of this third row are moreover provided with two sessile glands, one on each side of their base, and within them is a fourth row of abortive stamens. The fruit is berry-like, one-seeded, in a cup-like calyx.

*C. zeylanicum* is largely cultivated in Ceylon, for its bark, which furnishes the best Cinnamon. The bark is stripped off the branches, when it rolls up into quills, the smaller of which are introduced within the larger and then dried in the sun. The thinner the bark is as a rule, the finer its quality. Cinnamon is largely used as a condiment for its agreeable flavour, while its astringent and cordial properties give it a medicinal value. It is said to possess the special property of restraining uterine hemorrhage.

*C. Cassia* furnishes Cassia bark, which is much like cinnamon, but thicker, coarser, stronger, less delicate in flavour, and cheaper; hence it is frequently used to adulterate cinnamon. Its admixture, however, can be readily detected, even in a powdered state, according to Dr. Hassall. Cassia is grown in China, Java, &c. The German and Russian chocolate-makers prefer cassia to cinnamon, as affording a stronger flavour. The same, or some closely-allied trees, furnish Cassia buds, which are something like cloves, and, like them, consist of the unexpanded flower-buds; but they possess properties similar to those of the bark.

Other species of this genus, afford aromatic barks: such as *C. Oulilawan*, a native of Amboyna, whose bark has a flavour of cloves. *C. tiera*, a native of Malabar, is employed medicinally in fevers and dysentery: the seeds are the parts used; the bark is likewise employed as a condiment. The leaves of *C. nitidum*, dried, are said to have furnished the aromatic leaves called 'folia Malabathri'; indeed, it is surprising that the leaves of the cinnamon are not more often imported, as they, like the inner bark, though to a less extent, contain the volatile oil on which the fragrant aromatic properties depend. [M. T. M.]

**CINNAMON.** *Cinnamomum zeylanicum*, a tree cultivated in the tropics for its aromatic bark. —, **BASTARD.** *Cinnamomum Cassia*. —, **BLACK.** *Pimenta acris*. —, **ISLE OF FRANCE.** *Oreodaphne cupularia*. —, **SANTA FE.** *Nectandra cinnamomoides*. —, **WILD.** *Cassia alba*; also *Myrcia acris*.

**CINQUEFOIL.** The common name for *Potentilla*. —, **MARSH.** *Comarum palustre*.

**CIONIDIUM.** A small genus of Australasian polypodiaceous Ferns belonging to the *Dicksonia*, distinguished by having the indusium cup-shaped and standing out beyond the margin of the frond, and

having the veins reticulated. The only species known, *C. Moorei*, has a short decumbent rhizome, and pedately bipinnatopinnatifid fronds of membranaceous-herbaceous texture, which are studded with sori around the margin. The fructification of *Cionidium* is that of *Deparia*, the distinction between these two consisting in the reticulated venation of the former, and the free venation of the latter. [T. M.]

**CIPURA.** A small genus of Iridaceous plants closely allied to *Marica*, consisting of bulbous herbs with ensiform leaves and terminal heads of flowers. The species, which are but few in number, are found in tropical and subtropical America. The perianth has a very short tube and a six-parted limb, of which the inner or petaloid divisions are much the smaller; there are three stamens with distinct filaments inserted in the tube of the perianth, and a three-celled ovary containing numerous ovules, and surmounted by a very short style, and three petaloid undivided styles alternating with the stamens. *C. paludosa*, a native of humid meadows in Cayenne, has conico-globose bulbs, radical linear-lanceolate plaited leaves from three to five inches long, the scape shorter than the leaves, and bearing a short densely-imbriated distichous terminal spike of bluish flowers. [T. M.]

**CIRCEA.** A plant with a name so ominous as Enchanter's or Enchantress-Nightshade might well be supposed to be gifted with the most potent properties. It is, however, a humble herbaceous plant, belonging to the *Onagraceae*, growing to the height of about a foot and a half, with delicate egg-shaped leaves which taper to a point, and small white flowers tinged with pink, which are succeeded by small roundish seed-vessels thickly covered with hooked bristles. *C. Lutetiana*, the common species, is abundant in shady woods, where it frequently covers a large space of ground. It often too finds its way into shrubberies, where it is a pretty but troublesome weed, creeping extensively, and very difficult to eradicate. It has no affinity with any of the true nightshades; and the English name, according to Dr. Prior, has been transferred, by some blunder, from the mandrake to the present plant. It was called 'Enchanter's' from its Latin name *Circus*, after the goddess Circe. *C. alpina*, a closely-allied species, scarcely differs from the preceding except that it is of smaller size, and of more delicate habit; it is not unfrequent in Scotland and the north of England. French, *Circée*; German, *Enchenschraut*. [C. A. J.]

**CIRCINALIS, CIRCINATE.** Bent like the head of a crozier, as is the young leaf of a fern when it begins to grow.

**CIRCUMPOSITIO.** A layer; that is to say, a branch laid into the ground or layered in order that it may strike root.

**CIRCUMSCISSILE, CIRCUMSCISSUS.**

Out circularly round the sides, as the seed-vessel of *Anagallis*.

**CIRCUMSCRIPTIO.** The outline of anything.

**CIRCUMSEPIENTIA FOLIA.** Leaves which rise up like a funnel and surround the stem as if to protect the young shoots, as in the Marvel of Peru. Such is De Candolle's definition, but the term is very rarely used.

**CIRIER or CIRIER DE LA CAROLINE.** (Fr.) *Myrica cerifera*.

**CIRRHEÆ.** A genus of pseudobulbous Orchids from tropical America, with solitary ribbed leaves, and drooping racemes of flowers, yellowish, greenish, or spotted with purple. They are remarkable for their long column, which bears a one-celled anther at the back of the upper extremity, curving gracefully over a deeply three-lobed lip, the middle division of which turns back from the side ones. The proscolla or stigmatic point is extended into a slender tendril-like thread, whence the name.

**CIRRHIFEROUS.** Bearing a tendril.

**CIRRHIFORM.** Shaped like a tendril.

**CIRRHOPETALUM.** An extensive genus of small epiphytal Orchids, with solitary fleshy leaves proceeding from the top of roundish pseudobulbs. Their flowers are remarkable for having the lateral sepals prolonged into narrow streamers, by which the species are readily distinguished from *Bolbophyllum*. Between thirty and forty species are known, all from tropical Asia except *C. Thaurasi*, which inhabits the Mascaren and South Sea Islands. The singularly-formed flowers have made a few favourite objects of cultivation. The best are *C. fimbriatum*, *refractum*, *chinense*, and *Cumingii*.

**CIRRHOSITAS.** The production of tendrils.

**CIRRHUS** (adj. **CIRRHOSE**). A tendril. A slender twining organ by which a plant climbs.

**CIRSIUM.** A genus of Compound flowers belonging to the thistle group, distinguished from *Carduus* by having the receptacle covered with chaffy bristles, and the achenes crowned with a soft feathery pappus. Several British species are described by English botanists as belonging to the genus *Cnicus*. Numerous others occur in various parts of the continent, some having purple, and others yellow flowers, but none of sufficient interest to require further notice. [C. A. J.]

**CISSAMPELOPSIS.** The name given to a number of trailing shrubby plants of the Composite family which are found in India and the adjacent islands, as well as in S. Africa. They differ in little except habit from groundels (*Senecio*), in which genus indeed they are placed by some authors. Most of them have heart-shaped stalked

leaves with toothed margins, and their under-surface is invariably covered with short close-pressed white hairs. The yellow flower-heads, arranged in terminal or axillary panicles or corymbs, have an involucre of eight or ten scales, enclosing about a dozen florets, all of them tubular. The achenes have no beak, are somewhat angular in form, and crowned with a pappus of many rough hairs, arranged in a single series. [A. A. B.]

**CISSAMPELOS.** A genus of *Menispermaceæ*, with the climbing character of the ivy—*kissos* of the Greeks, and the clustered fruit of the vine—*ampelos*. Their flowers are dioecious. The male flowers have four sepals and four petals combined into a cup; the female flowers have two sepals fused into a somewhat fleshy two-nerved scale, frequently notched at the margin, and having externally a small bract, formerly considered as a sepal. The ovary is solitary. In drawing up the differential characteristics of this genus, the explanations of Hooker and Thomson as to the structure of these flowers have been adopted as being probably correct, though at variance with the account given by other writers. The most important plant of the genus is the Velvet Leaf, *C. Pareira*, a native of the West Indies, Central America, and India. It is an exceedingly variable plant with a climbing stem, the leaves of variable rounded shape, and dotted with velvety pubescence; male flowers in stalked hairy cymes, and female flowers in clusters, with large rounded bracts, and succeeded by sub-globose hairy scarlet drupes. The root of this plant furnishes the 'Pareira brava' of the druggists, which is used with much benefit in diseases of the bladder and urinary organs. Many other species are used as tonics and diuretics, while *C. glaberrima* and *C. ebractenta* are used as remedies for serpent bites. The root of *C. obtecta* is used in the manufacture of an intoxicating drink. [M. T. M.]

**CISSAROBRYTON.** A genus of *Vitaceæ* found in the Andes of Chili, and differing from its congeners in having a five-parted calyx, five petals, and three conspicuous slender styles. The only species known, *C. elegans*, is a little prostrate branching plant with slender woody stems and opposite roundish leaves an inch long; their stalks as long as the blade, which has three to seven deep notches, is slightly hairy above, and is covered underneath with a hoary down. The flowers are blue, in size and form made like those of the wood sorrel, and single from the axils of the leaves, supported on long slender stalks. [A. A. B.]

**CISSUS.** A genus of *Vitaceæ* scarcely differing from the vine (*Vitis*). The petals, however, usually separate before they fall, instead of remaining united at the tips as in *Vitis*, and are usually four instead of five; the disk is more conspicuous. The leaves are often more deeply divided. Most of the species are found within the

Tropics, especially in Asia; a few occur in North America. [J. T. S.]

**CISTACEÆ.** (Rock Rose family.) A natural order of Thalamifloral Dicotyledons, characterizing Lindley's Cistal alliance. Shrubs or herbs, often viscid, with simple entire leaves and showy flowers. Sepals three to five, persistent, unequal, the three inner twisted in the bud. Petals five, rarely three, falling off, often crumpled, twisted in an opposite direction from the sepals. Stamens numerous, not united. Fruit a one-celled capsule with parietal placentas, or imperfectly three to five-celled with central placentas. Seeds with mealy albumen; embryo curved or spiral. The plants are found chiefly in the south of Europe and north of Africa. They are very rare in North America, still more uncommon in South America, and scarcely known in Asia. They are usually resinous, and have a balsamic fragrance. The resin called *Ladanum* is procured from several species of *Cistus*. *Helianthemum vulgare*, the common Rock Rose of Britain, has remarkably irritable stamens, which in sunny weather move on being touched. There are eight known genera, and about 190 species. Illustrative genera: *Fumana*, *Cistus*, *Helianthemum*. [J. H. B.]

**CISTELLA, CISTULA.** A cell-like shield found among lichens in the genus *Sphaerophorum*.

**CISTOME.** A membranous sac which according to some, penetrates stomates, and reaches the bottom of the subjacent chamber. If this statement is correct the cistome must be a fold of the cuticle.

**CISTOPHORUM.** The stipe of certain fungi.

**CISTOPTERIS.** A mode of spelling which is sometimes adopted instead of *Cylopteris*. [T. M.]

**CISTUS.** A genus of the Rock Rose family, to which it gives the name, composed of handsome shrubs, many of them in cultivation, natives of Southern and Western Europe, North Africa, and the Canary Islands. They are commonly known as Rock Roses and Gum Cistus, but the latter name is the better of the two, as the former is equally applied to *Helianthemum*, from which this genus differs in having an imperfectly five or ten-celled capsule, while in *Helianthemum* the capsule is imperfectly three-celled. The greater portion of the species are elegant erect bushes, with opposite entire or sometimes toothed leaves, generally oblong or lance-shaped, and axillary or terminal flower-stalks bearing one or many flowers. These are made up of a five-leaved calyx, five large petals, numerous stamens, and an ovary crowned with a simple style. The flowers of all are handsome, and many of them in size and appearance resemble those of the dog-rose; they seldom last more than a few hours after expansion, and do not open in dull weather when there is no sunshine. In one group of

species the petals are white and furnished with a yellow or purple mark at their base; while in a second the petals are rose-coloured, each with a yellow spot at its base. None of them have yellow flowers, a colour so common among the *Helianthemum*.

The *Ladanum* or *Ladbanum* of Crete is a well-known gum, which exudes from the leaves and branches of *C. creticus*, and some other allied species. This plant is a handsome shrub, with oblong obtuse rough leaves with wavy margins and about an inch in length. The flowers are terminal and single or twin, the petals purple with a pale yellow spot at the base. The gum is collected in Crete by means of a kind of rake, with a double row of long leathern straps, employed in the heat of the day when not a breath of wind is stirring. Seven or eight country fellows, in their shirts and drawers, whip the plants with these straps, which, by rub-

*Cistus creticus.*

bing against the leaves, lick off a sort of odoriferous glue sticking to the foliage. Formerly it was said to be gathered from the beards of goats, which are fond of browsing on the foliage of the plant. The gum, by gently rubbing in the hands, emits a very pleasant balsamic odour, from the presence of a volatile oil. It was once used in time of the plague as a stimulant and expectorant, and as a constituent in plasters. About fifty hundredweight of it is annually sent from Crete to Turkey, where it is used as a perfume, and as a fumigation. The *Ladanum* of Spain and Portugal is derived from *C. induratus*. This is one of the most beautiful of the genus, and is very frequently to be met in gardens. In Portugal it is said to cover leagues of country. Its leaves are lance-shaped, entire, and three-nerved, the upper surface covered with a clammy glisten, and the under surface prominently three-nerved and covered with a dense white tomentum. The large white flowers are sometimes more than three inches across in one variety, the petals having a deep purple blotch at the base. The gum

is said to be obtained by boiling in water the summits of the branches. It has odour similar to that of the former, but is not in much repute.

A much more common plant in gardens is *C. cyprus*, which is often confounded with the former, but has large and always solitary flowers, while this has three or four flowers on a common stalk; the leaves are also stalked, while in *C. ladaniferus* they are sessile.

One of the most beautiful of the rosy-flowered species is *C. vaginatus*, a native of Teneriffe. Its hairy leaves are lance-shaped, three-nerved, and dilated towards the base, while the splendid large rose-coloured flowers are very numerous and in terminal panicles. The petals are crumpled and have wavy margins, bent inwards, with a yellow spot at their base. A large number are in cultivation, and upwards of thirty coloured figures of these plants are given in Sweet's *Cistinea*. [A. A. B.]

**CISTUS, GROUND.** *Rhododendron Chamaecistus*. —, GUM. *Cistus ladaniferus*, and *C. ledon*.

**CISTURAPES.** A name given by Lindley to the group of Cytinaceous parasites.

**CITHAREXYLON.** A considerable genus of trees or shrubs, belonging to the order *Verbenaceae*, natives of tropical and sub-tropical America. They have tetragonous sometimes spiny branches, opposite or verticillate leaves, and small racemose flowers each with a minute bracteole. The persistent calyx is cup-shaped or tubular; the limb of the corolla is subequally five-parted. The included stamens are inserted below the throat of the corolla on short filaments; they are subequal or the fifth is shorter than the others, sometimes rudimentary and sterile, on altogether absorbed. The ovary is four-celled, with one ovule in each cell. The juicy drupe is surrounded by the large cup-shaped calyx, and is two-stoned, each stone being two-celled. [W. C.]

**CITREOUS, CITRINOUS.** Lemon-coloured.

**CITRIOBATUS.** A genus of small thorny Australian trees or shrubs belonging to *Pittosporaceae*. Leaves alternate, shortly stalked, obovate, leathery, entire. Flowers small, solitary, sessile, axillary, with five sepals bracteated at the base; five petals united at the base; and five stamens. Fruit an orange berry with a leathery skin, sub-globular, about one inch and a half in diameter, eaten by the natives; seeds large. The plants are called the Native Orange and Orange Thorn by the Australian colonists. [J. T. S.]

**CITROSMA.** A genus of opposite-leaved bushes or small trees belonging to the *Mentaceae*, confined to the tropical parts of South America, and numbering upwards of fifty species. A large proportion of them have their parts, especially the leaves, covered with glands which

secrete an oily substance of a strong citron odour. Some of the species are known on this account by the name of Limoncillo, and the genus also derives its name from this circumstance. The leaves, sometimes three or four in a whorl, are either entire or toothed, and very often covered with rusty hairs, but sometimes smooth. The small green or yellow flowers without petals are numerous, disposed in axillary cymes, and either male and female on the same or on different plants. They are made up of a three or six-lobed cup-shaped calyx, which in the male encloses few or many stamens, and in the female a number of one-celled and one-seeded ovaries, each with a simple style; these are at length entirely enveloped by the fleshy tube of the calyx. This latter circumstance serves to distinguish the genus from its allies. The fruit is about the size of a pea when ripe. The name of the genus was formerly written *Citrosma*. [A. A. B.]

**CITRON, *Citrus medica*. —, FINGERED.** *Sarcodactylis*.

**CITRONELLA.** *Andropogon citratus*, which yields an essential oil used in perfumery.

**CITRONELLA.** (Fr.) *Artemisia Abrotanum*. Also applied to *Melissa officinalis*, and to the aromatic Guava.

**CITRONIER, or CITRONNIER.** (Fr.) *Citrus medica*.

**CITRONWORTS.** A name given by Lindley to the family of Aurantiaceous plants to which the Orange and Citron belong.

**CITROUILLE.** (Fr.) A race of large oblong Gourds derived from *Cucurbita Pepo*. —, PASTIQUE. *Cucumis Citrullus*.

**CITRUL.** The Water Melon, *Cucumis Citrullus*.

**CITRULLUS.** The Bitter Cucumber or Colocynthis, which furnishes a well-known cathartic drug, belongs to this genus of the gourd family, *Cucurbitaceae*, and is known by its unisexual flowers, which have a persistent five-parted calyx and corolla. In the male flowers, the stamens are free, united into three bundles, and the anthers are sinuous. The female flowers have an inferior three to six-celled ovary, a cylindrical three-cleft style, and kidney-shaped stigmas. The fruit is a many-seeded gourd. *C. Colocynthis* was originally a native of the warmer parts of Asia, but has now become widely diffused. The drug known as Colocynthis consists of the round fruits or gourds, which are imported either with the rind on or peeled, from Spain, the Levant, &c. The pulp in the interior of the fruit is light and spongy, and very bitter; from it a watery extract is made, which is much employed as a purgative in the form of pills. Some discrepancy exists as to the seeds of this plant, which some describe as bland and

nutritious, while others say that they are bitter and purgative. Certainly the dried dark-coloured seeds met with in this country are so; but it is stated that

*Citrus Colocynthis.*

the seeds are used as food at the Cape of Good Hope. An oil is also extracted from them for burning in lamps. [M. T. M.]

**CITRUS.** The Orange, Lemon, Citron, and other well-known fruits of a similar kind, are included in this genus of *Aurantaceæ*. Its distinguishing characteristics are: the presence of a cup-like calyx, numerous stamens irregularly united by their filaments into several bundles, a cylindrical style, and a pulpy fruit with a spongy rind. The leaves of these trees are also remarkable inasmuch as they consist of one leaflet, separated from the leaf-like stalk supporting it, by a distinct joint.

The most important species, in a medical or pharmaceutical sense, are the Citron, Lemon, and Seville Orange. The Citron, *C. medica*, furnishes two kinds of oil, used by perfumers, the essential oil of citron and the essential oil of cedar. The Lemon, *C. Limonium*, is employed for the sake of its aromatic bitter rind; its odour is due to the volatile oil in which it abounds. The juice of the Lemon is used as a refreshing beverage in fevers and scorbutic affections, and as effervescing lemonade to check sickness and nausea. As it is apt to decompose, crystallized citric acid is usually employed in its place as an antiscorbutic, and with the best effects. Lately it has been recommended in acute rheumatism. Lime juice is employed for similar purposes. The Seville or Bitter Orange, *C. Bigaradia*, is used for the sake of its rind and its flowers, which possess a stronger flavour and odour than the sweet orange. The rind is used as a stomachic and tonic, while the flowers yield by distillation orange-flower water. [M. T. M.]

The Citron, Orange, Lemon, Shaddock, and Lime have been referred to various species of *Citrus*; with regard to which botanists, however, are not agreed. It is even doubtful whether all of them, with their very numerous varieties, have not originated from *C. medica*. On this point

the following observations by Dr. Lindley in the *Journal of the Horticultural Society* (ix. 171), are important. He states that the above-mentioned fruits 'are all of Eastern origin, and mostly introduced into Europe in comparatively modern days, but of very ancient and general cultivation in Asia. The varieties known are very numerous and difficult to reduce according to their species, on the limits of which botanists are much divided in opinion. Those who have bestowed the most pains in the investigation of Indian botany, and in whose judgment we should place the most confidence, have come to the conclusion that the Citron, the Orange, the Lemon, the Lime, and their numerous varieties now in circulation, are all derived from one botanical species, *C. medica*, indigenous to, and still found wild in, the mountains of East India. Others, it is true, tell us that the Citron, the Orange, and the Lime are to be found as distinct types in different valleys, even in the wild state; but these observations do not appear to have been made with that accuracy and critical caution which would be necessary in the case of trees so long and so generally cultivated.'

The Citron, *C. medica*, is described by Theophrastus as abundant in Media, that is to say, in the north of Persia. Its fruit, according to Professor De Candolle, was carried to Rome in the beginning of the Christian era, or perhaps at an earlier period. The first attempts at its cultivation in Italy proved unsuccessful, and according to Gallezio, it was not established there till about the third or fourth century. The Jews cultivated the Citron at the time they were under subjection to the Romans, and used the fruit then, as at the present day, in the Feast of Tabernacles; but there is no proof of their having known this tree in the time of Moses. It is likely they found it at Babylon during their captivity, and brought it to Palestine on their return. Whatever may have been the diffusion of the species in Western Asia at that remote date, there is no evidence of its having been indigenous to Media, nor have modern travellers found it wild in Persia; but Dr. Royle found the species in the forests of Northern India. The Citron is cultivated in Cochin China, and in China, but Thunberg does not mention it as existing in Japan. Taking all the above facts into consideration, it is evident that the species is originally from the north of India, and as the habitat of every one of the Orange tribe is naturally rather limited, Professor De Candolle does not think that this extended in the case of the Citron, as far as the north of Persia. Probably the Citron was carried in that direction, and also into China at a very early period. In many countries they are easily naturalised. The seeds sow themselves in several of the colonies: for instance, in Jamaica. In its wild state the Citron grows erect with spiny branches. The flowers are purple on the outside and white inside. The fruit is large, oblong or ovate,

sometimes six inches long, the skin covered with protuberances, and of the well-known citron-yellow colour when the fruit is ripe. Of the cultivated varieties, some are oval, others round, and that called the Madras Citron has the form of an oblate sphere. In China there is a variety with its lobes separating into finger-like divisions, and hence called the Fingered Citron.

The Lemon, *C. Limonum*, of some botanists, *C. medica Limonum* of others, is, according to Dr. Royle, who found it growing wild in the North of India, named in Hindostanee Neemo, Leemo, Lechoo; in Arabic Limoun; and in Italian, Limone. Professor De Candolle states that it was unknown to the ancient Greeks and Romans; and that its culture only extended into the west with the conquests of the Arabs. On their spreading over the vast regions of Asia and Africa, they carried with them everywhere the Orange and Lemon. The latter was brought by them in the tenth century from the gardens of Oman into Palestine and Egypt. Jacques de Vitry, writing in the thirteenth century, very well describes the Lemon, which he had seen in Palestine; and doubtless it was by the crusaders first brought into Italy, but at a date which cannot be exactly ascertained. From the north of India it appears to have passed eastward into Cochín China and China, and westward into Europe, and it has naturalised itself in the West Indies and various parts of America. Fruit oval or ovate, terminated by a small blunt nipple-like point; skin smooth, rind much thinner than that of the Citron. The varieties are numerous. Lemons are chiefly imported for their agreeably acid juice and essential oil, and also for the manufacture of citric acid.

The Orange, *C. Aurantium* of those botanists who do not consider it to be probably only a variety of *C. medica*, is associated with the latter as a native of the north of India. According to Gallesio, instead of being found in the north of Africa, Syria, or even in Media, it was not at the time of Alexander the Great in that part of India which he penetrated; for it is not mentioned by Nearchus among the productions of the country which is watered by the Indus. But the Arabs, carrying their conquests further into India than Alexander, found the Orange more in the interior; and according to Professor Targioni it was brought by them into Arabia in the ninth century. Oranges were unknown in Europe, or at all events in Italy, in the eleventh century, but were shortly afterwards carried westward by the Moors. They were in cultivation at Seville towards the end of the twelfth century, and at Palermo in the thirteenth, for it is said that St. Dominic planted an orange for the convent of St. Sabina in Rome, in the year 1200. In the course of the same thirteenth century, the crusaders found Citrons, Oranges, and Lemons, very abundant in Palestine; and in the following

or fourteenth century, both Oranges and Lemons became plentiful in several parts of Italy. It appears, however, that the original importation of Oranges from India into Arabia and Syria occurred about a century earlier than that of Lemons. Gallesio states that Oranges were brought by the Arabs from India by two routes; the sweet ones through Persia to Syria, and thence to the shores of Italy and the south of France; and the bitter, called in commerce Seville Oranges, by Arabia, Egypt, and the north of Africa to Spain. Of the numerous varieties of this esteemed fruit, our limits will only admit of our noticing some of the more important.

The Sweet Orange has the leaves ovate-oblong, acute, somewhat serrated, with the stalk more or less winged. The flowers are white. The fruit is well known. There are many varieties; that called the China Orange is the common Orange of the markets. The Blood Red or Malta Orange has the fruit round, rough red or reddish-yellow outside, with a pulp irregularly mottled with crimson. The Saint Michael's Orange has the fruit rather small, pale yellow and seedless, with a thin rind and very sweet pulp; it is one of the most delicious and productive varieties. The Noble, or Mandarin Orange is small flattened and deep orange, with a thin rind which separates spontaneously from the pulp, so that when quite ripe the latter may be shaken about inside; it is exceedingly rich and sweet. In China, where this delicious variety has been raised, the fruit is chiefly consumed in presents to the Mandarins, hence its name. It is now, however, very successfully cultivated in Malta and in the Azores. The Sweet-Skinned Orange is the Pommo d'Adam, or 'Forbidden fruit' of the shops of Paris, but not of London; its skin is smooth, deep yellow, with a thick sweet soft rind. The above are some of the principal sorts of sweet oranges; but there are many other varieties, many of which possess, however, but little merit.

The Common Seville, or Bitter Orange, or Bigarade, *C. Bigarada*, has a round dark fruit with an uneven, rugged, extremely bitter rind. This sort is largely imported for the manufacture of bitter tincture, and the preparation of the candied orange-peel. To this section are referred the various kinds of Bigarades, among which may be named the Horned, Curled-leaved, Purple, Double-flowered, and Myrtle-leaved. These, especially the Horned and Curled-leaved, are cultivated chiefly for their flowers, which are powerfully fragrant.

Of the Bergamot Orange, *C. Bergamia*, both flowers and fruit possess a peculiar fragrance; and from each of them an essence of a delicious quality is extracted.

The Lime, *C. Limetta*, bears ovate or roundish pale yellow fruit with a boss at the point; its juice is acid and slightly bitter. There are varieties differing in form and in the thickness of their rind. Among them is one called by the Italians Pommo d'Adam, because they fancy the depres-

sions on its surface appear as if it still bore the marks of Adam's teeth.

The Shaddock, *C. decumana*, derives its common name from Captain Shaddock, by whom it was first carried from China to the West Indies, early in the eighteenth century. The shoots are pubescent; the leaves large with a winged stalk; the fruit very large, weighing sometimes ten to twenty pounds, roundish, with a smooth, pale yellow skin, and white or reddish subacid pulp. When the fruits attain their largest size they are called Pompeleons, or Pompelemousses; those of the smallest size form the 'Forbidden fruit' of all the English markets.

The Orange tribe cannot be grown in this country without protection in winter. In some parts of Devonshire, however, they require but very little, as for example, at Combe Royal, near Kingsbridge, where very fine specimens of Oranges, Citrons, and Lemons, &c., have been for many years obtained from trees planted against a wall, and protected only with a movable wooden shelter in winter. The first Oranges, it is stated, were imported into England by Sir Walter Raleigh, and reared by his relative Sir Francis Carew at Beddington in Surrey. These trees are mentioned by Bishop Gibson, in his additions to Camden's *Britannia*, as having existed for a hundred years previous to 1695; but finally they were entirely killed by the great frost in 1739-40, after they had attained the height of eighteen feet, with stems nine inches in diameter. Trees of the Orange tribe naturally live to a very great age in a soil and climate which suit them. Even under artificial treatment there are some remarkable instances of their longevity. There may be seen, in the orangery at Versailles, a tree which was sown in 1421. It is growing with its roots in a large box, and appeared very healthy when we saw it lately. The Orange tree at the convent of St. Sabina at Rome is thirty-one feet high, and said to be upwards of 600 years old. At Nice, where the tree may be considered naturalised, growing quite in the open air, there was in 1782, according to Risso, a tree which generally bore 5,000 or 6,000 oranges, and which was more than fifty feet high with a trunk which required two men to embrace it. In Cordova, the noted seat of Moorish grandeur and luxury in Spain, there are Orange trees still remaining, which are considered to be 600 or 700 years old.

Under favourable circumstances, the productiveness of the Orange is astonishing. In an account of the gardens and orange-grounds of St. Michael's in the Azores, by Mr. Wallace (*Journal of the Hort. Society*, vii. 236), we are informed by the author, who resided at St. Michael's for several years, that the orange grounds vary from one to sixty acres in extent, and are surrounded with high walls and tall-growing trees as shelter, not from the cold but from the sea-breeze. The grounds are rarely occupied wholly by Orange

trees, for Limes, Citrons, Lemons, Guavas, &c., are scattered about in them. Orange trees were first introduced to the Azores by the Portuguese. There are only two kinds of oranges cultivated at St. Michael's, viz., the Portugal and the Mandarin; many varieties of the former exist, and they are greatly improved by the genial climate of St. Michael's. The Mandarin Orange has not been many years in the island, nevertheless there are some trees of it fourteen feet high. This capital little orange has lately been exported to England, where it realises a higher price than the common St. Michael's. The largest orange tree which Mr. Wallace measured was thirty feet high, the stem being seven feet in circumference at the base; but many larger trees, destroyed by the corrus, had been cut down. The produce of the trees is almost incredible; props are always used to prevent the weight of the fruit from breaking down the branches. An orange tree in the quinta, or orange garden of the Barão das Lameiras produced twenty large boxes of oranges, each box containing upwards of 1,000 fruit—in all 20,000 oranges from one tree. Two hundred ship-loads of oranges are annually exported from St. Michael's, being nearly 200,000 boxes. [R. T.]

CIVETTE. (Fr.) *Allium Schœnoprassum*.

CLADENCHYMA. Branched parenchyma.

CLADIUM. A genus of Cyperaceous plants belonging to the tribe *Rhynchosporæ*. The spikelets are one to two-flowered; glumes five or six; bristles wanting; nut with a thick fleshy coat, tipped with the conical base of the jointless style. Twenty-one species are mentioned in Steudel's *Plantæ Cyperaceæ*; these have an extensive geographical distribution, the majority being natives of New Holland. *C. Mariscus* is a native of Britain, and the most northerly of the species. It is a handsome aquatic plant, not of frequent occurrence, though plentiful in some districts. [D. M.]

CLADOBIUM. An obsolete name of *Sagphyglottis*.

CLADOCARPI. A small section of Mosses containing those anomalous genera in which the fruit is not truly lateral but terminates short lateral branchlets. The British genera belonging to this section are *Sphagnum*, *Mielichhoferia*, *Fissidenes*, and *Cinclidatus*; but the two latter contain species which are not truly cladocarps. [M. J. B.]

CLADOCAULON. A Brazilian Ericaceaceous plant, an undershrub with much-branched leafy stems and flowers in heads, the male flowers being in the centre, the females at the circumference of the head. These latter present the distinguishing feature of the genus, that is to say, a double perianth, each row of three linear oblong segments adherent at the base, the outer segments reflexed, and ultimately

deciduous, the inner ones shorter, thinner, and persistent. In other particulars it does not differ from the other genera of the order. [M. T. M.]

**CLADODYSTROPHIA.** An affection to which oaks and other trees are subject in light soils, or when past maturity. The upper branches are less perfectly nourished than the lower, and therefore more rapidly decay. It has also been supposed that trees become stag-headed in consequence of decay of the tap root, possibly from the attacks of fungi, the terminal branches having an especial reference to it. This, however, is mere matter of speculation, though the main branches and roots have in many cases direct communication with each, some particular root more especially supplying some particular branch, as is indicated by the buttress-like spurs which connect the two. Where the tree is without leading shoots, the tips of the several branches sometimes assume a similar condition. [M. J. B.]

**CLADONIA.** A genus of Leciðineous Lichens which is characterised by its ultimately globose or button-shaped fruit growing at the tips of vertical hollow shrub-like or cup-shaped processes, arising from a foliaceous or crust-like thallus, to which they bear an inverse proportion. The fructifying disc is often of the brightest scarlet, but sometimes assumes other tints as pinkish-brown or black. The species are numerous even when reduced within reasonable limits, and extend into the coldest regions, while some are cosmopolites. *C. rangiferina* extends almost to the extreme limits of vegetation, and affords an abundant supply of excellent food to the reindeer, without which the inhospitable northern parts of our continent could scarcely be inhabited. *C. pyxidata*, a common species in woods and hedge-banks, is supposed to afford a good medicine in the whooping cough; while *C. sanguinea*, rubbed down with sugar and water, is successfully applied in the thrush of infants in Brazil. [M. J. B.]

*C. rangiferina*, the Reindeer Moss, is the badge of the clan McKenzie.

**CLADOPHORA.** A genus of Chloro-sperms closely allied to *Conferva*, and distinguished by its branched habit. The species are numerous, and grow in various situations, but the most characteristic, as *C. glomerata* and *rupestris*, occur either in rivulets or on sea-rocks. A few of the species of warm countries attain a considerable size. *C. mirabilis* was once celebrated as affording a supposed instance of transformation from a green-spored into a rose-spored alga; but it has since been ascertained that the cladophore serves merely as a matrix to the rhodospERM which surrounds the threads with its dilated base. The reproductive bodies are minute zoospores with thong-like appendages contained in the articulations. The species are found in most parts of the globe. [M. J. B.]

**CLADOPTOSIS.** A name given to a singular affection to which several of our forest trees, as the oak and willow, are subject, in which the small branches snap off with a regular circular fissure, leaving a cup-shaped scar, somewhat similar to that which takes place when a leaf or fruit separates at the stalk. The branch was of course previously dead, and the separation seems to depend upon a vital process by means of which the dead are thrown off from the living tissues. After pears have fallen, a repeated separation into joint-like portions takes place, in a somewhat similar manner, between the component parts and the branch which gave them birth. After cold summers, vine branches are apt to fall off, a process which is facilitated by the peculiar formation of the stem, there being a transverse layer of cellular tissue at each bud. This is sometimes called Phriganoptosis. Larger branches occasionally fall off in a like manner in the elm, but more generally, though the line of demarcation is well-marked, the branch does not fall till it is tightly pressed by the new layers of bark destined after its disappearance to close up the cavity. [M. J. B.]

**CLADOS.** In Greek compounds = a branch.

**CLADOSPORIUM.** A genus of naked-spored Moulds of which one species, *C. herbarum*, is found in all habitable parts of the world on decaying substances, whether animal or vegetable, covering them with olive patches which when in fruit are shot with green. It consists of short brown-jointed waved threads, which bear on their sides oblong or elliptic spores with one or two transverse divisions. In damp seasons, wheat is often discoloured at the tip with this fungus, and it is then said to be tagged. Another species, *C. dendriticum*, is common on apple leaves, and when attacking the fruit causes the orbicular dark spots which are so common on apples, and which have been named by Fries *Spilocœa*. The same species, or a mere variety of it, attacks pears in a similar way, and sometimes materially affects the health of the tree by infesting the leaves and young shoots. [M. J. B.]

**CLADOSTACHYS.** A genus of *Amaranthaceæ* allied to *Celosia*, but having the stamens free, not cohering as in that genus, and the three stigmas linear and revolute, not capitate. *C. muricata* is a much-branched Indian shrub with alternate stalked ovate-acute smooth leaves, and elongated paniculately-arranged spikes of small white flowers. [J. T. S.]

**CLADOTHAMNUS.** A genus of *Pyrolacææ* consisting of a shrub from Western Arctic America with much-branched stems sessile wedge-shaped oblong glabrous leaves, glaucous below, and solitary axillary shortly-stalked flowers, with a five-parted calyx, five petals, ten stamens, a thread-like style, incurved at the apex,

with a globular five-lobed stigma; capsule sub-globose, five-celled. [J. T. S.]

**CLANDESTINA.** A genus of *Orobanchaceae* containing a single species, a parasite on roots in damp woods in the South of Europe. It is a small plant with a short branching scaly subterraneous stem, the bluish-violet flowers being seen in clusters rising from the apex of the stem as if from the earth. The four-cleft calyx is bell-shaped; the upper lip of the corolla helmet-shaped, the lower short and blind. The ovary is surrounded at the base by a half-moon-shaped hypogynous gland. The capsular fruit contains four or five seeds attached to two linear parietal placentas. This genus is nearly related to *Lathraea*, in which it was formerly included; it differs chiefly in having erect flowers, and a definite number of seeds on small placentas. [W. C.]

**CLAOXYLON.** A genus of *Euphorbiaceae* composed of trees or shrubs, natives of the tropical portions of the eastern hemisphere. They are nearly allied to *Mercurialis*, but differ in their arborescent habit as well as in the petal-like disc of the female flowers. The leaves are long-stalked, oval or lanceolate, and entire or toothed at the margins. The nerves of the leaves and the various parts of the flowers of many species are deeply tinged with a dark red colouring matter which is said to be used as a dye. The inconspicuous generally green flowers are arranged in slender racemes furnished with bracts, each bearing in its axil a cluster of flowers; these in the male are made up of a calyx with three or four deep divisions enclosing numerous stamens; and in the female of a similar calyx enclosing a three-lobed ovary, crowned with a three-branched style, and seated on a disc formed by three dark red petal-like glands. The capsular fruits are three-celled, about the size of a pea, and each cell contains one seed. [A. A. B.]

**CLARKIA.** A small genus of *Onagraceae*, indigenous to California and North Western America, contributing to our gardens two of the best known and most esteemed of popular annuals. The genus is well characterised by its clawed petals, eight stamens, of which the alternate four are shortest and sterile, four-lobed stigma with broad roundish spreading lobes, and cylindrical four-furrowed four-celled seed-vessel, opening when ripe by four valves. The species are all erect branching plants, with entire or toothed foliage, and showy reddish-purple flowers produced singly from the axils of the leaves. *C. pulchella* has the largest flowers, and is remarkable in its typical form for its petals being three-lobed with a tooth on each side of the claw, though in the variety *integrifolia* of garden origin the lobes are obliterated. The leaves of this species are long and narrowly lance-shaped, quite entire, and the stem and branches are drooping at the summit before the expansion of

the flowers. *C. elegans* is a taller plant with slender twiggly shoots, quite erect in all stages of their growth, ovate toothed foliage, the flower-buds drooping before expansion, and the bluntly rhomboidal petals quite undivided. [W. T.]

**CLARY.** *Salvia sclarea*. Hornminum Clary is *Salvia Hornminum*, and Vervain Clary, *Salvia Verbenaca*.

**CLATHERUS.** A genus of gasteromycetous *Fungi* belonging to the phalloid group, remarkable at once for the beauty of their colour and elegance of form, combined with the most abominable odour. The receptacle to which the deliquescent fruit-bearing cells are attached, forms a scarlet network, which bursts forth from a gelatinous volva. In *C. crispus*, which occurs in warmer climates, the edge of the meshes is beautifully crisped. The closely-allied *Ilodictyon cibarium* is known to the New Zealanders by a name implying Thunder-dirt, and forms a coarse article of food. *C. cancellatus* is common in the south of Europe, and occurs occasionally in the southern parts of England, as at Torquay and the Isle of Wight, also in Ireland. [M. J. B.]

**CLATHERUS** (*adj.* **CLATHERATUS**). A lattice; a membrane pierced with holes and forming a kind of grating, as in the *Olivandra fenestralis*.

**CLAUDEA.** The most beautiful genus of rose-spored *Algae*. It is named after Claude Lamouroux, a distinguished French algologist. Three species only are known, of which two occur on the coasts of Australia and Tasmania, and the third on those of Ceylon. The frond proceeds from a thread-shaped stem, which is continued into the marginal rib of a flat unilateral open net-work formed of several series of anastomosing slender mid-ribbed leaflets. Each net-work, when fully formed, is ten to twelve inches long, and about an inch broad, and is elegantly recurved like a scimitar. The capsules are in the mid-rib of metamorphosed primary and secondary leaflets, and contain at the base a dense tuft of pedicellate pyriform spores. The tetrasperms are contained in the swollen bars of the second series of network in transverse rows. *C. elegans* sometimes grows at the mouth of rivers where the saltiness is much modified, and then assumes a large size with increased delicacy. The above account is taken from Dr. Harvey's *Phycologia Australasica*, a work which ought to be in the hands of every lover of seaweeds. [M. J. B.]

**CLAUDINETTE.** (*Fr.*) *Narcissus poetica*.

**CLAUSILE.** A name given by Richard to his macropodal embryo, when its radicle is united by the edges and entirely incloses all the rest of it.

**CLAVALIER.** (*Fr.*) *Xanthoxylon Clava Heroulti*.

**CLAVARIA.** A genus of the clavate division, *Clavariet*, of hymenomycetous

**Fungi**, distinguished by their fleshy substance and confluent stem. The species are either simple or branched, and are extremely numerous, and from the great difference of form, colour, and division assumed under different circumstances, often extremely difficult to recognise. The surface is mostly smooth, but sometimes wrinkled longitudinally. Many of them afford excellent articles of food, but they are not much used in this country, probably from the scurveness of the larger species. *C. vermicularis*, which comes up frequently on our lawns, looking like little bundles of candles, is sometimes very abundant, and extremely delicate when dressed. We have seen *C. rufescens* exposed for sale in Hanover, where it is much esteemed. [M. J. B.]

**CLAVARIACEÆ.** A natural order of hymenomycetous *Fungi* distinguished by their vertical growth and superior hymenium, which extends to the very apex, and is distributed equally on all sides (amphigenous). The species generally grow on the ground amongst leaves, a few appear on rotten wood, and some of the lower kind on decaying herbaceous stems. We believe all the species which produce white spores are wholesome; some, moreover, with yellow spores are esculent, though one or two are doubtful. [M. J. B.]

**CLAVATUS, CLAVIFORMIS.** Gradually thickening upwards, from a very taper base; as the spadix of *Arum maculatum*.

**CLAVICULA.** A tendril.

**CLAVIGERA.** The name applied by the elder De Candoille to three Mexican plants of the Composite family, since shown by Dr. A. A. Gray to differ in no way from *Brickellia*, and therefore placed in that genus which numbers about thirty species, mostly Mexican, and is distinguished from *Eupatorium* by the many-atriate instead of five-angled achenes. [A. A. B.]

**CLAVIJA.** A genus of the Myrsinæ family, comprising a number of shrubs or small trees, confined to the tropical parts of South America. Their unbranched rod-like stems are furnished at the top with a crown of large alternate coriaceous leaves, often two feet in length, quite smooth, oblong in form, and entire or spinously-toothed at the margin. The waxy white or orange-coloured flowers are small and disposed in erect or drooping racemes which are shorter than the leaves, and either proceed from their axils or from the bare stem where the leaves have fallen. The tube of the corolla being very short, and the five stamens having five roundish fleshy scales alternating with them, are characters which distinguish the genus from the others in the family. The fruits are fleshy and contain numerous seeds embedded in a pulp which is said to be eatable. In size they vary, but are seldom larger than a pigeon's egg. The genus bears the name of J. Clavijo Faxardo, a Spanish naturalist.

*C. ornata*, a native of Brazil and Guiana, is frequently to be met with in plant stores, where it is always a prominent object from its straight unbranched stems, bearing on their apex a cluster of large handsome leaves often a foot or more in length. Its starry wax-like flowers, of a bright orange colour, are produced in great abundance, and are disposed in erect racemes. The root of some of the species is said to be emetic. [A. A. B.]

**CLAVULA.** The receptacle, or sporocase of certain fungi.

**CLAVUS.** The disease which produces ergot in grasses; so called because it causes the young grain to grow into the form of a nail or club.

**CLAW.** The long narrow base of the petals of some flowers; the analogue of the petiole.

**CLAYTONIA.** A genus of Purslanes, chiefly North American consisting of dwarf annual or tuberous-rooted perennial plants with entire leaves, and small white or flesh-coloured flowers in terminal racemes. Generically they are distinguished by a calyx of two oval permanent sepals, five petals usually with short claws cohering at the base, five stamens inserted on the claws, one style with its apex three-cleft, and an ovary ripening into a one-celled capsule, opening by three valves, and containing from three to six seeds. *C. perfoliata*, which is naturalised in some places in England, is a weedy little species with fibrous roots, broadly ovate veinless radical leaves on long foot-stalks, and numerous simple naked flower-stems, bearing at the summit a roundish leafy bract formed by the cohesion of two opposite leaves, from which arise one or more short racemes of small white flowers with notched petals. The leaves of this plant are used like those of the common purslane, *Portulaca oleracea*. The perennial *Claytonias* have for the most part small tuberous or spindle-shaped roots, from which arise a few simple stems a foot high, bearing about the middle a single pair of opposite linear or lanceolate leaves, and being terminated by a loose drooping raceme of pink flowers veined with red. The species are rare in cultivation, but *C. virginica* is sometimes met with. They are popularly known in America by the name of Spring Beauty, from the early season at which they flower. [W. T.]

**CLEARING NUT.** An Indian name for the nut of *Strychnos potatorum*.

**CLEARWEED.** An American name for *Pilea pumila*.

**CLEAVERS.** *Galium Aparine*.

**CLEGHORNIA.** A Cingalese and Indian genus of Apocynaceæ, the plants of which have small white flowers with a calyx of five lobes alternating with five glands; a salver-shaped corolla with oblique lobes and without scales in its throat; included anthers, arrow-shaped and sharply-pointed

at the top; two ovaries, with a short style and large stigma; the fruit consisting of two large follicles. [M. T. M.]

**CLEISOSTOMA.** A genus of caulescent Orchids, with leathery narrow distichous leaves, and long tough roots by which they cling to the bark of trees in various parts of the East Indies. They have the pouch-like lip and fleshy flowers of *Sarcobium* and *Sarcanthus*, differing from the former in having the orifice of the pouch closed by a large projecting tooth, and from the latter in the pouch being absolutely one-celled. Sixteen or seventeen species are known, all having small flowers of little beauty.

**CLEISTES.** A genus of terrestrial leafy-stemmed Orchids inhabiting tropical America. In habit they resemble *Arethusa*. The flowers are terminal and nearly solitary, of some purple tint. *C. rosea*, with large nodding flowers, is one of the finest; *C. paludosa* is quite insignificant.

**CLEMATIS.** An extensive genus of twining shrubs with variously-cut opposite leaves, belonging to the *Ranunculaceae*, among which they are distinguished by their single perianth (a coloured calyx but no petals), and by the long feathery tail attached to their one-seeded carpels. The only English species, *C. Vitalba*, Virgin's-Bower, is so called on account of its being used for covering bowers; another name, *Traveler's-Joy*, was probably given to it because of its being, in winter, among the most conspicuous and ornamental of wayside plants, often covering hedges for a considerable distance with its feathery seed-vessels, from the resemblance of which to grey hair the plants is sometimes called Old-Man's Beard. The flowers are greenish-white, and destitute of perfume. French *Herbe aux gueux*, from its ragged appearance. *C. Flammula* is the sweet-scented species common in gardens, a native of Southern Europe and Northern Africa; a variety of this is known, having larger flowers tinged with rose-colour, expanding in October. Other ornamental species are *C. Florida*, of which a variety with large double white flowers is to be preferred as being the handsomest and remaining the longest in bloom; *C. Ficticia*, of which there are several varieties with single or double flowers, blue, purple, or red; and *C. azurea* and *C. lanuginosa*, insignificant blue-flowered Japanese species. *C. tubulosa* is a showy perennial with large blue flowers. [Many garden hybrids remarkable for their profuse blooming properties have been raised, and of which *C. Jackmanni* is the type.] [C. A. J.]

**CLEMATITE COMSUNE.** (Fr.) *Clematis Vitalba*. — **ODORANTE.** *Clematis Flammula*.

**CLEMATITIS.** *Aristolochia Clematidis*.

**CLEONE.** A genus of Capparids chiefly found in the tropical regions of the New World, and presenting, in common with the other genera of the order, some in-

teresting features. It is distinguished by the possession of a calyx of four pieces; a corolla of four erect petals, usually with long claws; six stamens having long distinct filaments; and a many-seeded pod-like fruit borne on a stipe or stalk of varying length. Most of the species are annual plants of erect habit, with digitate leaves of from three to seven lanceolate leaflets, and flowers in terminal bracted corymbs lengthening into racemes. One of the commonest species is *C. pungens*, a robust clammy plant, attaining a height of four or five feet, with spiny stipules, foot-stalks as well as under side of midribs armed with sharp prickles, and racemes of rose-purple flowers; the anthers of this species are yellow, by which it may be known from *C. spinosa*. *C. rosea* resembles *pungens* in general habit, but is quite free from prickles, is less robust, and its leaves consist of but five leaflets, the uppermost and lowest of three only. *C. speciosissima* has handsome rose-coloured flowers, leaves with five to seven leaflets, petals as long as the flower-stalk, and a pod on a stipe longer than itself. The species are chiefly remarkable for their beauty, but are reputed to possess a pungent taste like that of mustard. [W. T.]

**CLEONELLA.** A small genus of annual *Capparidaceae*, the leaves of which are trifoliate, and the flowers have four somewhat spatulate petals with short claws and six separate stamens attached to the stalk supporting the ovary, which latter is gourd-shaped and one-celled, becoming a pod-like capsule. The plant is a native of Mexico and N. America. [M. T. M.]

**CLERODENDRON.** A considerable genus of *Verbenaceae*, natives of tropical districts chiefly in Asia, but found also in Africa and America. They are shrubs or trees with opposite or ternate simple leaves, and loosely cymose or capitate flowers in terminal panicles or thyrses, more rarely axillary. The calyx is campanulate or inflated, and five-toothed or five-lobed. The corolla-tube is slender, the limb spreading and nearly equally five-lobed. There are four stamens inserted in the tube of the corolla, and usually much exerted; the anthers have two parallel cells, opening longitudinally. The ovary is four-celled, with a single pendulous or laterally attached ovule in each cell. The slender exerted style has two acute stigmatic lobes. The fruit is a drupe surrounded by the calyx, its kernel usually large, separating into two two-celled or four one-celled nuts. This genus is nearly related to *Volcaneria* and *Agiphila*, but is separated from the former by its fruit, and from the latter by its pentamerous flower. Nearly eighty species have been described. They have been arranged under two sections — 1. *Eulerodendron*, in which the corolla is salver-shaped with a short tube scarcely longer than the calyx; and 2. *Siphonanthus*, in which the corolla is funnel-shaped with a very long tube. The plants have slightly bitter sub-astringent properties, and on

this account some of them are used in Indian medicine. [W. G.]

**CLESTINES.** Large cells of parenchyma, in which raphides are often deposited.

**CLETHRA.** A genus of *Ericaceae*, consisting of shrubs or trees, with alternate serrate deciduous leaves, and bearing white flowers in terminal hoary racemes. They are natives of North and tropical America. The calyx is five-parted; the corolla has five distinct obovate-oblong petals. There are ten hypogynous stamens, with inversely arrow-shaped anthers, which open by terminal pores or short slits. The ovary is three-celled with many ovules in each cell. The style is slender with a three-lobed stigma. The capsule is three-celled, with many seeds in each cell, three-valved, and enclosed in the calyx. [W. G.]

**CLEYERA.** A genus of *Ternstroemiaceae*, comprising a few Indian and Japanese evergreen bushes with camellia-like leaves, and small axillary white or yellowish flowers, sometimes sweet-scented. These flowers are stalked, and have a calyx of five leaves, five petals, numerous stamens in two or three series, and an ovary surmounted by a style which is three-parted at the top. The five free petals, and the numerous stamens slightly adhering to their base, are the chief distinguishing features of the genus. [A. A. B.]

**CLIANTHUS.** A genus of *Leguminosae* in New Zealand, Norfolk Island, New Holland. It is nearly related to *Sumerlandia*, a Cape genus which has bladder pods, while the pods in the present are coriaceous. The plants are herbaceous or woody branching shrubs, with unequally-pinnate leaves made up of eight to sixteen pairs of linear or elliptical leaflets half an inch long. The large handsome flowers are in terminal or axillary racemes. The calyx is bell-shaped and five-toothed. The upper petal or standard is oval, pointed, and bent backwards, much larger than the wings and shorter than the keel, which is skiff-shaped. The pod is stalked, somewhat woolly inside, and contains a number of seeds. The name of the genus is derived from the Greek, and signifies Glory Flower, a name peculiarly applicable to the plants. The best known species is *C. puniceus*, called Parrot's-Bill in New Zealand, from the resemblance of the keeled petal to the bill of that bird. This plant was introduced in 1831, and is often to be met with in greenhouses, or on open walls with a southern aspect, where it flowers freely if protected in winter. It seldom attains more than six feet in height, although in Ireland, where the climate seems to suit it better, it is sometimes to be seen covering on a wall a surface of twelve or fourteen feet square. The pinnate-leaves are about six inches long, and the leaflets, about half an inch in length, are smooth above and slightly pubescent underneath. The flowers grow in oval clusters hanging from the leaf-axils, each flower more than

three inches from the tip of the standard to the tip of the keel, and of a deep blood colour.

*C. Dampieri* is a native of the desert regions of Australia, and is also in cultivation. In habit it is much like the former, but it does not grow to such dimensions. The whole plant is of a pale green colour, and is thickly covered with long white hairs. The peduncles proceed from the axils of the leaves, and bear on their apex four or five scarlet flowers, larger and of a much brighter colour than those of the former, the standard having also a large black-purple boss at its base. This plant has the most beautiful flowers in the genus, but is unfortunately difficult of cultivation. *C. carnosus*, a climbing species, native of Norfolk Island, is better referred to *Stereorrhiza*; it has flesh-coloured flowers, and although a pretty plant, is not to be compared with the others for beauty, the flowers being much smaller. [A. A. B.]

**CLIDEMIA.** A genus of *Melastomaceae* from tropical America, containing hairy branched shrubs with opposite stalked leaves, generally unequal in size, with three to seven ribs, and white or rose-coloured flowers, often silky. The calyx is adherent to the ovary at the base; petals five or six, rarely four; stamens twice as many as the petals; ovary hairy, with as many cells as there are petals; berry fleshy, often edible. [J. T. S.]

**CLIFFORTIA.** A genus of small apetalous South African bushes, belonging to the Rosaceae family, whose principal distinction lies in the three-toothed calyx and very numerous stamens. The leaves are alternate, small, and composed of two or three leaflets; when the latter is the case, the two lateral ones are small, and more or less united to the central one, so that the leaves appear to be simple. The flowers are small, and seated in the axils of the leaves. In the males the calyx tube is contracted at the top, and bears about thirty stamens. In the females the calyx is similar to that of the male, and encloses one or two achenes, each furnished with a lateral bearded or feathery style. The holly-like leaves of *C. thicifolia* are used by the Boers as an emollient and expectorant in coughs. *C. ornata* is remarkable for the form and arrangement of the leaves, which are composed of two orbicular leaflets with notched margins, and are so closely set on the stems that they lap over each other in the manner of the scales of a fish. [A. A. B.]

**CLIFFORTIACEAE.** A name given sometimes to *Rosaceae* proper, including *Sanguisorbeae*, as distinguished from *Amygdaleae* and *Pomaceae*.

**CLINANDRUM.** The bed of the anther of orchids; an excavation of the top of the column, in or on which the anther is seated.

**CLINANTHIUM.** A flat or broad space, on which flowers are packed closely; the

receptacle of composites; a shortened, widened axis.

**CLINANTHUS.** A name given to a group of Peruvian Amaryllids; subsequently changed to *Clitantes*, and now merged in *Coburgia*. [T. M.]

**CLINIUM.** In Greek compounds = receptacle. Also an accessory part of certain fungi, consisting of very small long simple or branched cells, bearing a spore at their end.

**CLINOPODIUM.** One of the names of the Wild Basil, now referred to *Ocimum*.

**CLINTONIA.** A small genus of Lobeliads, consisting of dwarf annuals with the aspect and habit of *Lobelia*, but differing from that genus in the corolla being without a tube, and in the character of the seed-vessel, which, instead of being a half egg-shaped two-celled capsule opening when ripe by pores at the summit, is a long slender three-angled pod of one cell only, with seeds attached to two parietal placentas, and splitting when ripe into three narrow thong-like valves. Of the several species composing the genus, but two are known in British gardens, *C. pulchella* and *C. elegans*, both natives of California. The former is an elegant little plant, with slender prostrate branched stems, sparingly clothed with linear blunt foliage, and producing from its upper axils numerous flowers, with the upper lip of two spreading deep blue segments, and the lower lip very broadly wedge-shaped, three-lobed, blue at the margin, the centre being white and yellow with several deep purple spots. The pod is so long and slender that it presents the appearance of a foot-stalk rather than that of a seed-vessel. *C. elegans* is distinguished by its leaves being ovate instead of linear, and its flowers of a pale blue colour. The name of this genus has also been applied by Rafinesque to a small group of plants belonging to the lily tribe. [W. T.]

**CLIOCARPUS.** A genus of Brazilian shrubs of the family *Atropaceae*, remarkable for being densely covered with small star-shaped hairs. The flowers are stalked, and are set in the axils of the leaves. The calyx is hairy, platter-shaped at its base, with five small pouches near its junction with the flower-stalk, the upper portion divided into five lance-shaped spreading segments, which increase in size as the fruit ripens, and become erect; their margins also are everted and touch those of the adjacent segments, so that a kind of tube is formed. The corolla is wheel-shaped, hairy, its divisions with a prominent nerve. The five stamens arise from a thickened rim at the base of the corolla, and have short wavy filaments, and large four-celled anthers. The fruit is a many-seeded berry included within the calyx. [M. T. M.]

**CLIOOOOOA.** A genus of *Linaceae* from South Australia, scarcely distinct from *Linum*, the only differential characters being the imbricated, not contorted, aestiva-

tion of the corolla, and the capsule splitting into ten cocci. [J. T. S.]

**CLITANTHES.** A name proposed for a group of Amaryllids, since referred to *Coburgia*. [T. M.]

**CLITOCYBE.** A sub-genus of white-spored Agarics with strongly decurrent, or acutely-adenate gills, the stem elastic with a fibrous outer coat, and the pileus convex when young, though depressed when old. It contains a great many species, some of which are excellent articles of food. *Agaricus nebularis*, for example, which occurs in woods with a compact obtuse pileus, clouded with grey, is one of the most delicate of mushrooms; and *A. geotropus*, especially the form called *subinvolutus*, is not to be despised. [M. J. B.]

**CLITOPILUS.** A sub-genus of rose-spored Mushrooms with decurrent gills, and the pileus confluent with the fleshy or fibrous stem. *Agaricus prunulus*, which is a frequent inhabitant of our woods, and readily recognised by its primrose-whitish depressed pileus, narrow rose-coloured decurrent gills, and mealy scent, belongs to this sub-genus, and is excellent either stewed or pickled. It must not be confounded with *A. gambosus* (see TRICHOLOMA) which sometimes bears the same name. Most of the species are too small to be of much value. [M. J. B.]

**CLITORIA.** A large genus of Pea-flowered plants belonging to the Leguminosae family, and nearly related to *Centrosema*, but differing in the standard having no spur-like appendage near its base. The genus is widely distributed, being found in tropical Asia, Africa, and America; in the latter country in the greatest numbers, and almost exclusively on the eastern side of the Andes. The greater portion of the species are large climbers, scrambling over trees to a great height; some few are erect, and several are twiners among bushes. The alternate pinnate leaves are made up of one or many pairs of opposite leaflets, and a terminal odd one. The peduncles arise from the axils of the leaves, and bear one or many large purple blue white or red flowers, often two to three inches long. The tubular five-toothed calyx is furnished with two bracts at its base; the standard is large and oval, notched or bifid at the apex, and narrowed into a claw at the base, the wings are much smaller than the standard, and the keel smaller than the wings and sometimes almost hidden by them. The straight pod is sometimes winged, and contains a number of seeds.

*C. Ternatea*, so called because the seeds were first brought from the island of Ternate, one of the Moluccas, is a very common plant in most tropical countries, and has long been in cultivation in England. In habit it is much like the common pea. Its leaves have two to four pairs of oval leaflets and a terminal odd one. The large handsome flowers grow in the axils of the leaves, and are of a beautiful blue colour,

the standard with a white or yellow blotch at its base. They sometimes occur double, and a variety with white flowers also exists. The corollas of the blue variety are said to afford a blue dye in Cochinchina, but it is not permanent, and Rumphius says that they are used for colouring boiled rice in Amboyna. The root is reputed to be as powerfully purgative as jalap; and in India, where it is sold in the bazaars in pieces about the thickness of two quills, it is given to children to promote sickness and vomiting. The Butterfly Pea, *C. Maritima*, has a curious distribution, being found in the Southern American States and Mexico, and appearing again in the Khasia Mountains in India without being found in any intervening place. It is a slender twining plant with leaves made up of three oval or lanceolate thin leaflets, about two inches long, and axillary peduncles bearing one or three flowers of a light blue colour. *C. arborescens*, a native of the West Indies and the adjoining mainland, is the only one of the numerous large scandent species peculiar to South America, which are in cultivation. Its leaves are pinnate and more than a foot in length, and the leaflets sometimes eight inches long and four broad. The large pale-blue flowers are numerous and in racemes, which are shorter than the leaves. Some of the species were formerly known under the names *Neurocarpum* and *Ternstroemia*. [A. A. B.]

CLIVERS, or CLEAVERS. *Galium Aparine*.

CLIVIA. A beautiful genus of Amaryllidæ, to which the name *Imantophyllum* has also been applied. The latter, however, corrected to *Imantophyllum*, Sir W. J. Hooker now proposes to apply to a distinct though allied plant of South Africa called *I. miniatum*. The *Clivias* consist of herbs with fasciculate fleshy roots, and distichous lorate radical persistent dark-green leaves, from among which springs a plano-convex scape, bearing at top a crowded umbel of drooping flowers. These are formed of a six-leaved cylindrically funnel-like perianth curved on the upper side, the divisions having fourfold diversity, and being connivent into the form of a tube, overlapping and partially united at the base; the three exterior ones are the shortest; there are six equal slightly protruded stamens affixed to the base of the segments, a three-lobed stigma, and an inferior three-celled ovary containing many ovules and seeds, the cells, according to Herbert, being three-angled. The species are of South African origin. *C. nobilis* is a very handsome plant, often seen in green-houses, remarkable for its sturdy-looking harsh evergreen retuse two-ranked leaves, and producing a large head of numerous (forty to fifty) pendulous, club-shaped, orange-scarlet flowers tipped with green. *C. Gardenii* is a similar plant from Natal. *C. cyrtanthiflora*, a plant raised in the Belgian gardens, and known under the name of *Imantophyllum cyrtanthiflorum*, is said

to be a hybrid between *C. nobilis* and the *Imantophyllum miniatum* above referred to. It has distichous lorate leaves, and an erect flower-scape, bearing numerous drooping slender funnel-shaped flowers, of a pale flame-colour with green tips. [T. M.]

CLOCHETTE DES CHAMPS. (Fr.) *Convolvulus arvensis*. — D'HIVER. *Galanthus nivalis*.

CLOSTERANDRA. An imperfectly known plant, now referred to *Papaver*. The filaments of the stamens are dilated in the middle. The ovary is obovate, one-celled, and surmounted by five radiating stigmas which fall off when the capsular fruit is ripe. It comes from Persia. [M. T. M.]

CLOT-BURR. *Xanthium*.

CLOUDBERRY. *Rubus Chamemorus*.

CLOUDED. When colours are unequally blended together.

CLOVE BARK. The bark of *Cinnamomum Cullavan*.

CLOVE CASSIA. The bark of *Dicypellum Caryophyllatum*.

CLOVE GILLIFLOWER. The aromatic-scented double-flowered whole-coloured varieties of *Dianthus Caryophyllus*.

CLOVE NUTMEG. The fruit of *Agathophyllum aromaticum*.

CLOVE TREE. *Caryophyllus aromaticus*. The cloves of commerce are the dried aromatic flower-buds. —, WILD. *Eugenia acris*.

CLOVER. The common name for *Trifolium*, especially applied to the sorts cultivated for fodder. —, ALSIKE. *Trifolium hybridum*. —, BOKHARA. *Melilotus leucantha*, a fodder plant, very grateful to bees. —, BUSH. An American name for *Lespedeza*. —, PRAIRIE. An American name for *Petalostemon*. —, SOOLA. *Badystrum coronarium*. —, SWEET. An American name for *Melilotus*.

CLOVES. The small bulbs formed within the mother-bulb of certain plants; such as garlic.

CLOVEWORDS. A name sometimes used for the caryophylaceous family to which the clove gillflower belongs.

CLOWESIA rosea. A very rare orchid, with the habit of *Catasetum*, said to be a native of Brazil. It has erect racemes of concave white flowers delicately edged with rose-colour, broad fringed petals, and a saccate three-lobed lip the edge of which is broken up into innumerable thread-shaped glands. The anther lies at the bottom of an upright toothed hood. The caudicle resembles an hour-glass slit at the back.

CLOWN'S ALLHEAL. *Stachys palustris*.

CLUBBING. A peculiar condition or hypertrophia affecting the roots of cabbages and other allied parts, in which the

whole force of vegetation is carried downwards to the destruction of the leaf and stem. The main root is mostly affected, but the disease sometimes affects the laterals. The structure of the root is much altered, so that on division it looks marbled like a traffic, and many of the cells gorged with highly nitrogenous matter. The disease is local, or where not local, capricious, and probably depends upon peculiar chemical conditions of the soil. In districts which are subject to it, the most effectual remedy appears to consist in putting a small quantity of wood-ashes, which contain several salts of potash, into the hole in which the root of each plant is placed. [M. J. B.]

**CLUB-GRASS.** A common name for *Corynephorus*.

**CLUB-MOSS.** A common name for *Lycopodium*.

**CLUB-RUSH.** A common name for *Scirpus*.

**CLUB-SHAPED.** The same as Clavate.

**CLUSIA.** A large genus taken as the type of the *Clusiaceæ* or *Guttiferae*, the latter name referring to the fact that the greater portion of the plants secrete in more or less quantity a milk-like or yellow resin. *Clusia* is chiefly distinguished by its capsular five or ten-celled fruit, which splits when ripe, each cell having many seeds; and by the numerous stamens, whose anthers open along their whole length, and not by a small pore or slit at the apex. All are trees or shrubs peculiar to Tropical America, and grow in very humid hot places. A great portion of them are parasitical on other trees, and a few send down stout root-supports from their thick branches similar to those of the banyan tree. The leaves are opposite, entire, very leathery in texture, mostly obovate in form, and furnished with numerous parallel nerves which are very evident in dried specimens, but almost imperceptible in the living plants. The greater portion have roseate flowers, but in a few they are white or yellow; in the larger-flowered species there are seldom more than two or three together in the axils of the upper leaves, but in the smaller-flowered ones they are numerous and disposed in a sort of panicle. In the males the calyx is of four to six leaves, the petals four to eight, and the stamens very numerous. In the females, which have a calyx and corolla like the male, a few abortive stamens surround the ovary, which is crowned by a flat radiating stigma. The fruit is a dry or fleshy capsule splitting up when ripe into five or ten portions.

The genus bears the name of Charles de l'Ecluse or Clusius, a celebrated botanist of the sixteenth century. The leaves vary little in form throughout the genus; those of *C. grandiflora*, a native of Surinam, are from seven inches to a foot long, and its beautiful white flowers from five to six inches in diameter. Nearly allied to this,

but smaller in all its parts, is *C. insignis*, a Brazilian plant, whose flowers 'weep a considerable quantity of resin from the disc and stamens, so much so indeed, that Von Martius says he obtained an ounce from two flowers; this resin rubbed down with the butter of the chocolate-nut, the Brazilian women employ to alleviate the pain of a sore breast.' Other large flowered species, such as *C. alba*, *C. rosea*, and *C. flava* in the West Indies, yield an abundant tenacious resin from their stems, which is largely used for the same purposes as pitch; it is at first of a green colour, but when exposed to the air assumes a brown or reddish tint. The Caribs use it for painting the bottoms of their boats.

Among the smaller-flowered species the most interesting is the *C. Galactodendron*, a native of Venezuela. This plant, according to M. Desvieux, is one of the Palo de Vaca or Cow-trees of South America. Its leaves are about three inches long, oboval in form, and narrowed towards the base. The bark is thick, covered with rough tubercles, and its internal tissue becomes red when exposed to the air. In extracting the milk from this tree the inhabitants make incisions through the bark till they reach the wood, these incisions are said to be made only before the moon is full, as they imagine the milk flows more freely then than at any other time. One tree is said to yield a quart in an hour. When the inhabitants find themselves at a distance from their homes, they make use of the milk for themselves and their children; its use is accompanied by a sensation of astringence in the lips and palate, which is said to be characteristic of all edible vegetable milks.

*C. Duca* yields a resin known in Columbia by the name of Duca, and burnt for the sake of its pleasant odour. Upwards of thirty species are enumerated. [A. A. B.]

**CLU-ACEÆ** The Gamboge family, a natural order belonging to the Thalamifloral Dicotyledons, usually called *Guttiferae*; which see. [J. H. B.]

**CLUSTERED.** Collected in parcels, each of which has a roundish figure; as the flowers of *Cuscuta*.

**CLUYTIA.** A genus of *Euphorbiaceæ* composed of numerous dioecious bushes, confined to Africa and found in the greatest number at the Cape. The double disc of the male flowers readily serves to distinguish the genus from its allies. The alternate stalked leaves are destitute of stipules and vary in form from oval to linear; in some they are evergreen, but in others they fade in the autumn, whilst a few are charged, as well as the young branches, with glandular dots. The small, generally green flowers are in cymes in the axils of the leaves, numerous in the males, and few or single in the females. In the former they are made up of a five-leaved calyx, five petals, and five stamens supported on a central column and arranged like the branches of a chandelier; the base of the

column is surrounded by two rows of glands, five of them large and two or three-lobed, and five smaller, each of them entire or two-lobed. In the female flower the calyx and corolla is the same as in the male, but the disc is made up of five blind glands only, and the three-lobed ovary is crowned by a three-branched style, each branch blind at the point and bent back on the ovary. The fruit is a three-celled capsule with three seeds. The only reported useful species is *C. lanceolata*, a native of Abyssinia, where it is said to be used for stopping dysentery in cattle. [A. A. B.]

**CLYPEA.** A name which has been given to certain *Menispermaceæ*, now referred to *Stephania*. [M. T. M.]

**CLYPEATE.** Having the form of an ancient buckler; the same as *Scutate*.

**CLYPEOLA.** A genus of small annual herbs, belonging to *Cruciferae*, natives of Southern Europe and temperate Asia. They have the habit of the annual species of *Alysum*, but differ in having an indehiscent orbicular, flattened and margined pouch containing a single seed. [J. T. S.]

**CNEMIDIA.** If to the flowers of a large *Physurus* are added the foliage and habit of some herbaceous-leaved *Cypripedium*, the reader will form some idea of this singular genus of Orchids. The few species known are all Indian. *C. angulosa* has also been called *Govindovia nervosa*, and *Dacisma angulosa*.

**CNEMIDOSTACHYS.** A genus of *Euphorbiaceæ*, known also as *Microstachys*, and composed of herbs seldom more than two feet high, with twiggy branches, and alternate, linear, entire or serrate leaves. The inconspicuous flowers are male and female on the same plant; the males in slender spikes, have a three-parted calyx and three free stamens; the females, single in the axils of the leaves, have a calyx like the males, and a three-lobed ovary, crowned with a three-parted style. The capsule, about the size of a pea when ripe, is either smooth or covered with rough points, and is three-celled, each cell with a single seed. The greater portion of the species are Brazilian. One (*C. Chamelica*) is common to India and Africa, and another, which has been called *Elaeochroton aspericoccum*, is found in Tropical Australia. [A. A. B.]

**CNEORUM.** A genus of uncertain position, but closely allied to the *Rutaceæ*. It consists of small shrubs inhabiting the Mediterranean region, the Canary Isles, etc. They have narrow, entire leaves; yellow flowers with three or four sessile equal petals, larger than the sepals, inserted beneath the disc; three or four stamens attached to the stalk bearing the three or four-lobed ovary, which has two ovules in each of its three or four compartments. The fruit when ripe consists of three or four segments, which separate one from the other, and are fleshy externally, bony internally, and divided into two cavities

by a spurious transverse partition. The species will grow in the south of England in sheltered situations. [M. T. M.]

**CNEORUM.** (Fr.) *Daphne Cneorum*.

**CNESTIDIUM.** Dr. Planchon has described under this name a Central American tree of the order *Connaraceæ*. It has compound leaves covered with thick red down; clustered flowers, which have a calyx consisting of five parts, adhering together for a time, but at length breaking irregularly into two or three divisions; ten stamens, five of which are shorter than the rest, and confluent in a ring at their base; and five ovaries with as many thread-shaped styles. The fruit consists of a single follicle from the suppression of the remaining four, covered with red down, and containing a single seed. [M. T. M.]

**CNESTIS.** A name derived from the Greek word signifying to scratch, in allusion to the hairs on the fruit, which irritate the skin. It is applied to a genus of *Connaraceæ* consisting of shrubs frequently of climbing habit, with alternate compound thick leaves, and clusters of five-parted flowers; which bear ten stamens, five shorter than the remainder, and five sessile ovaries, with two ascending ovules. The fruit consists of five or fewer follicles, covered with stinging hairs, and containing but one seed. Two or three species are in cultivation, natives of Guinea, the Mauritius, etc. [M. T. M.]

**CNICUS.** A thistle-like genus of *Compositæ*, known by the following characters:—Bracts of the involucre leathery, extended into a long hard pinnated spine; fruits furrowed, marked with a broad scar on one side; pappus in three rows, the outer horny, short, the next composed of ten long bristles, the third of ten short bristles. The English plume thistles, formerly included in a genus of the same name, but differing from the above, are now referred to *Carduus*. Of the true genus *Cnicus* the most remarkable is *C. benedictus*, a native of the Levant and Persia, but now widely distributed. The plant was formerly esteemed as a tonic, diaphoretic, etc., but is now little used. [M. T. M.]

**CNIDOSCOLUS.** A genus of *Euphorbiaceæ*, composed of a few shrubs or herbaceous plants, all of them confined to tropical America. On the one hand they are nearly related to *Jatropha*, on the other to *Mauhot*, but differ from the former in having no petals, and from the latter in the filaments of their stamens being united into a central column, not free. Their stems are often fleshy and gouty, and are furnished with stalked leaves, which in most cases are armed with straight hairs, which sting most virulently; the blades are sometimes entire, but mostly palmately-lobed. The small white flowers are arranged in terminal or axillary cymes, the females few and occupying the central portion of the cyme; the males more numerous and occupying

the lateral parts. In both males and females the calyx is tubular with a five-lobed limb, and encloses in the former ten stamens united into a column and arranged in two tiers; and in the latter a three-lobed ovary crowned with three stigmas torn at the apex. The three-celled capsular-fruit is about the size of a large pea, and covered with sharp hairs, each cell containing but one seed.

*C. stimulans* is a plant of the Southern American states, and has palmately-lobed leaves from four to eight inches long. The lacerated segments are covered with spreading hairs, which sting fearfully the bare feet of the negroes when they tread on them; it is sometimes called on this account 'Tread Softly.' Its tuberous roots are said to be eatable like those of the cassava or manihot. *C. quinquelobus* has been in cultivation, but it stings so terribly that few people care to keep it. The effects of the sting are various on different constitutions. Some on being stung fall down and are quite unconscious for a length of time; but others are not so affected. In both cases an excruciating pain is felt, which lasts for some days, and the parts swell and sometimes continue swollen, accompanied with an itching sensation for months. [A. A. B.]

COACERVATE. The same as Clustured.

COADNATE, COADUNATE. The same as Connate.

COALITIO. The growing of one thing to another; as that of petals, which produces a monopetalous corolla, &c.

COARCTATE. Contracted; drawn close together.

COARCTURE. The neck of a plant. See Collum.

COBÆA. This small genus of Phlox-worts consists of climbing tendrilled plants, with pinnate foliage, and large bell-shaped flowers produced singly from the leaf axils. Although at first sight they appear to have little in common with the other plants of this order, and really differ essentially in habit, they yet agree with them in their most important structural features. The genus is distinguished by its large leafy permanent five-parted calyx; declinate stamens and style; three-celled ovary surrounded at its base by a fleshy annular disc; and large flat winged seeds, imbricated in a double row. *C. scandens*, the most interesting species, is a well-known summer climber of very rapid growth. Its leaves are composed of three pairs of elliptic leaflets, the midrib being terminated by a branched tendril; it has large bell-shaped flowers, which are at first green, but ultimately assume a deep violet hue. *C. macrostema* has smaller yellowish-green flowers, with stamens twice as long as the corolla, and the segments of the calyx lanceolate. [W. T.]

COB-NUT. A variety of the Hazel, *Cory-*

*lus Avellana*. —, JAMAICA. The seeds of *Omphalea triandra*.

COBURGIA. A genus of ornamental *Amaryllidaceæ*, having tunicated bulbs, linearly linear glaucous leaves, and a two-edged scape supporting a terminal umbel of few showy flowers. The perianth is funnel-shaped, with an elongated angular incurved tube, swollen towards the top, a regular six-parted imbricated somewhat spreading limb, and a short campanulate cup, bearing on its margin the six stamens and six intermediate bidentate lobes; the ovary is three-celled with numerous ovules. There are eight or ten species known, and these are natives of Peru. The type of the genus, *C. incarnata*, is a very handsome plant, with bulbs like those of the Jacobaea lily, five or six oblong linear bluish, slightly glaucous leaves, and a scape two and a half feet high, supporting a four-flowered umbel of pendent flowers, about five inches in length, of a brilliant salmon-orange colour, the tube of which is bluntly three-cornered, very slender at the base, widened upwards and dividing into a moderately-spreading limb of six ovate-elliptic segments an inch long, lighter in colour and more pinky than the tube, and with a green central stripe. The crown is short and erect, with six green bifid lobes between the stamens, which about equal the limb in length and are shorter than the style. *C. trichroma*, a species with a five-flowered umbel and flowers three inches long, the tube light red, the limb white within, green without, and with green-tipped teeth to the cup, is said to be cultivated in pots with great care in Mexico, where it flowers at various seasons. *C. variegata* has four-flowered umbels, the tube of the flowers yellow and red, and the limb yellow outside, white within, margined with rose, and tipped with green. *C. lutea*, formerly named *Clinanthus*, and subsequently *Clinanthus*, has a two-flowered scape, the flowers yellow and about two inches long. The genus was named in honour of the Prince of Saxe Coburg, now king of the Belgians, who, when resident at Claremont, was a great patron of horticultural and botanical science. The name has also been applied to another group of amaryllids, now merged in *Hippeastrum*. It is written *Coburgia* by Dr. Herbert. [T. M.]

COBWEBBED. Covered with loose, white, entangled, thin hairs, resembling the web of a spider.

COCA. *Erythroxylon Coca*, the leaves of which are used as stimulants by the Peruvian Indians.

COCALLERA. A Brazilian name for a decoction of *Oroton perdicipes*.

COCARDEAU. (Fr.) *Mathiola fenestralis*.

COCCIDIA. A name applied to that form of the conceptacles in the rose-spored *Alga*, which consists of globular tubercles

with a cellular wall continued from the substance of the frond, whether partly confluent with it or free, and not opening in general by a terminal pore. Examples are afforded by *Rhodynia* and *Gracilaria*. The elongated processes in such algae as *Gigartina mamillata* are simply called tubercles. In this species, at least, there is a pore for the exit of the spores. [M. J. B.]

**COCBIGROLE.** (Fr.) *Fritillaria Meleagris*.

**COCCEINEUS.** Pure carmine colour, slightly tinged with yel'

**COCCEINIA.** A climbing shrub of the Gourd family, common in the hedges of India, where it grows like our bryony. *C. indica*, the only species, has large white dioecious flowers, with five stamens united together by their filaments into a column bearing three parcels of wavy anthers. The female flower has three stamens, united in three parcels; and the style is short and trifid. The fruit is oblong, marked with ten white lines; when ripe it is of a red colour, bursting irregularly, and having several seeds provided with a gelatinous covering. The ripe fruit is used by the natives in their curries; the leaves and other portions are also used medicinally. [M. T. M.]

**COCOCBRYON.** A South African climbing shrub of the Pepper family has been made the type of a genus with the above name. The flowers are perfect, in densely crowded stalked spikes placed opposite to the leaves, and each flower protected by stalked peltate roundish bracts; there are two stamens, and sometimes a third; and the ovary is sessile, the style short. The fruit is a berry, crowned by the persistent style. *C. capense* possesses stomachic properties. [M. T. M.]

**COCOCYPSELUM.** A genus of *Cinchonaceae* with a four-parted calyx; a funnel-shaped inflated corolla; a two-celled, many-seeded berry; and a style partly divided into two. The name refers to the vase-like form of the fruit. *C. repens*, a West Indian creeping-plant, is in cultivation, and is interesting from its blue-purple berries. [M. T. M.]

**COCODES.** Resembling pills; consisting of spheroidal granulations.

**COCOLOBA.** A genus of Polygonaceous plants, one of which, *C. uvifera*, is known in the West Indies as the Seaside Grape, from the peculiarity of the perianth, which becomes pulpy, and of a violet colour, and surrounds the ripe fruit. By this character also the genus is distinguished among its fellows. The pulpy perianth has an agreeable acid flavour. An extract is prepared from the plant, which is so astringent as to rival kino in its effects. [M. T. M.]

**COCULUS.** This name is liable to mislead the general reader, who might suppose it to apply to the plant producing the poisonous berries called *Cocculus indicus*.

These, however, are the produce of an allied genus *Anamirta*: which see. *Cocculus* belongs to the same family, *Menispermaceae*, and consists of climbing shrubs, with unisexual flowers having six sepals, six petals, and six stamens; the female flowers have three ovaries placed on a short stalk, the styles erect, cylindrical. The fruit is a drupe with a bony shell, containing a curved seed. *C. laurifolia* forms an exception to the general rule in this genus, inasmuch as its stems are erect, not climbing. The plant producing Calumba root was formerly referred to this genus, but is now included in *Jateorhiza*. The root of *C. villosus*, an Indian species, is used in decoction in cases of rheumatism, &c., while the fruits furnish a kind of ink. See also *Tinospora*. [M. T. M.]

**COCCLUS.** A shell; a carpel, which separates with elasticity from an axis common to itself and others.

**COCE DOLCE.** The Italian name for the seeds of Sweet Fennel, *Feniculum dulce*.

**COCHÈNE.** (Fr.) *Pyrrus Aucuparia*.

**COCHINEAL-FIG.** *Opuntia cochiniifera*.

**COCHLEAR.** A term used in describing aestivation; when one piece, being larger than the others, and hollowed like a helmet or bowl, covers all the others; as in *Aconitum*.

**COCHLEARIA.** A genus of *Cruciferae*, represented in this country by the dissimilar-looking Horse-radish and the Scurvy-grass, in the essential parts of whose flowers, however, the correspondence is close. The points of distinction between this genus and its allies are the entire white petals, the stamens not being toothed, and especially the roundish pod or silicle, the valves of which are very convex, the partition between them very broad. The embryo is so folded up that the young root or radicle lies along the edge of the two flat cotyledons or seed leaves.

*C. Armoracia* is the common Horse-radish whose large coarsely-toothed rough leaves, and tall stem bearing a profusion of white flowers, are well known. The lowest leaves are frequently deeply and irregularly divided like the teeth of a comb, the upper ones become smaller and narrower. The root-stock is the part used for culinary purposes for its pungent taste. Dreadful accidents have occurred from mistaking the root of acornite for Horse-radish, as mentioned under *Aconitum*. The plant very rarely perfects its fruit in this country. *C. officinalis*, the Scurvy-grass, is a small low growing plant, with thick egg-shaped cordate leaves, the upper of which clasp the stem; unlike the preceding species, the pods have a very prominent rib in the centre of each valve. This plant was formerly used as an antiscorbutic, and is still used in salads, as watercress is. It is common in some parts of Scotland. *C. danica* and *C. anglica* are probably only varieties of this species. [M. T. M.]

**COCHLEARIFORM.** Spoon-shaped.

**COCHLEATE.** Twisted in a short spiral, so as to resemble the convolutions of a snail-shell; as the pod of *Medicago cochleata*, or the seed of *Salicornia*.

**COCHLIA violacea.** A small orchid-accous epiphyte from Java, with fleshy leaves, and small purple flowers growing in heads.

**COCHLIDIOSPERMATE.** Seeds which are convex on one side, and concave on the other, owing to unequal growth, or anomalous structure, as in *Veronica*.

**COCHLIDIUM.** A synonym of *Mono-gramma*, a genus of curious small tropical ferns. [T.M.]

**COCHLIODA densiflora.** A handsome Peruvian epiphytal orchid, with thin pseudobulbs and parchment-like leaves. The flowers appear in dense spikes, and have the lip adnate to the column as in *Epidendrum*; but the pollen apparatus is that of the *Vandee*. A second unpublished species of the genus has been sent from the Quitinian Alps by Dr. Jameson.

**COCHLOSPERMUM.** A genus of small trees or shrubs, natives of Tropical India, Africa, and America, as well as in North Australia. They are sometimes placed among the *Cutaceae*, or among the *Fernatrimiacoe*, but Benthani and Hooker include them in *Flacous tuaceae* (*Bizineae*). They are easily recognized by their palmately-lobed leaves, which are alternate, furnished with long stalks, and bear much resemblance to those of some of the maples. The large yellow flowers are in terminal panicles, and generally open and wither before the leaves make their appearance. They are composed of a five-divided calyx, five large nearly round petals, and very numerous stamens surrounding a one-celled ovary crowned by a single unbranched style. The capsular fruit when ripe is in size and form like a pear, and opens with three or five valves. The seeds are small, very numerous, and covered with a cottony down.

*C. Gossypium* is a shrub or small tree found in the peninsula of India. Its five-lobed leaves are smooth above and downy underneath, and, including the stalk, more than a foot long. The numerous yellow flowers in terminal panicles are about four inches across. From the stem of this plant a gum called *Kuteera* is obtained, and it is used as a substitute for gum tragacanth because of its viscosity. The cottony substance which adheres to the seeds is sometimes used for stuffing pillows and cushions. Much like this is *C. insignis*, a native of Brazil, but its leaves are smaller and have serrate lobes. The Brazilians make use of a decoction of the roots of this plant against internal pains, and principally against those which are the result of *Intis* and other accidents; they also affirm that this decoction cures abscesses which have already formed.

*C. Planchoni*, a native of Western Africa,

is a shrub about five feet high, with alternate three or five-lobed leaves which are pubescent underneath. According to Mr. Barter, who gathered the plant, 'each shoot rises from a stool, is unbranched, and bears on the apex a cluster of yellow flowers three to four inches across. The roots are large and succulent, and yield the only yellow dye with which the people are acquainted. It is a common plant on the river Quorra.' Another species, *C. tinctorium*, a native of Senegambia, is said to have a thick tuberous root-stock, which furnishes a yellow dye, known to the natives as Fayar, and used for dying cotton stuffs, as well as in medicine in cases of amenorrhoea. The flowers of this only are known, and very likely it is not different from the last-mentioned species. The woolly covering of the seeds gives rise to the name of the genus. [A. A. B.]

**COCKLE-BURR.** An American name for *Xanthium*.

**COCKSCOMB.** *Celosia cristata*.

**COCK'S-HEAD.** *Onobrychis Caput-galli*.

**COCK'S-SPUR THORN.** *Cratægus Crus-galli*.

**COCOA or CACAO.** The seeds of *Theobroma Cacao*.

**COCOA-NUT.** The nut of *Cocos nucifera*. —, **DOUBLE** or **SEA.** The nut of *Lodoicea sechellarum*.

**COCOA-PLUM.** The fruit of *Chrysobalanus Icaco*.

**COCOA-ROOT** or **COCO.** The root of *Colocasia antiquorum*, used as an esculent in tropical countries.

**COCO, LE PETIT.** *Theophrasta Jussia*.

**COCOS.** The well-known Cocoa-nut tree is the type of this genus of palms, to which, in addition, about a dozen other species belong. They mostly form tall graceful trees, and the majority of them are natives of the tropical regions of America, one only, the common Cocoa-nut, being found in Asia or Africa. Their leaves are very large and pinnate. Their flowers are of separate sexes produced on the same spike, both having a calyx consisting of three sepals, and a corolla of three petals, the males containing six stamens united at the base, and the females an egg-shaped ovary, with a short style and three stigmas, and sometimes six barren stamens. The fruit is either elliptical, or egg-shaped and three-sided, and contains a single seed enclosed in a hard bony shell, which has three round holes at its base, and is surrounded by a dry fibrous husk.

The Cocoa-nut Palm, *C. nucifera*, is now so extensively cultivated throughout the tropics, that it is impossible to ascertain its native country; there can be no doubt, however, that it is indigenous to some part of Asia, probably Southern India. It exists in vast quantities on the Malabar and Coromandel coasts, and adjacent islands,

growing in the greatest luxuriance upon sandy or rocky sea-shores, and evidently preferring the vicinity of the sea, although it sometimes occurs a considerable distance inland. It is also common in Africa, America, and the West Indies. Its extensive geographical distribution is accounted for by the fact of the tree growing in such close proximity to the sea, that the ripe fruits, falling on the beach, are washed away by the waves, and afterwards cast upon some far-distant shores, where they readily vegetate. It is in this way that the coral islands of the Indian Ocean have become covered with these palms. It is also worthy of remark, that the triangular form of the fruit facilitates its progress through the waves.

The Cocoa-nut Palm has a cylindrical trunk, sometimes as much as two feet in diameter, and rising to the height of sixty or one hundred feet, its outside being marked with scars, indicating the places from which leaves have fallen away. It is surmounted by a crown of gracefully curved feathery or pinnate leaves, each of which is from eighteen to twenty feet in length, and composed of a strong tough central footstalk, with numerous narrow long and sharp-pointed leaflets arranged along both sides of it, giving the entire leaf the appearance of a gigantic feather; the base of the stalk spreads out so as to clasp the stem, and is surrounded by a kind of fibrous network of a light-brown colour. The flowers are arranged on branching spikes five or six feet long, and enclosed in a strong tough pointed sheath (spathe), which splits open on the under side, displaying the delicately white but inconspicuous flowers. They are succeeded by branches containing from twelve to twenty fruits, each of which is about a foot long by six or eight inches wide, of a three-sided form, and covered by a thick fibrous rind or husk, enclosing a single seed contained in a hard shell, which is what is commonly called the Cocoa-nut in this country.

The uses of this palm are so numerous that space will only allow us to give a brief outline of them. In this country we know comparatively little of its value. It is true that we are indebted to it for several very useful articles, such as cocoa-nut fibre, cocoa-nut oil, and the cocoa-nuts themselves; but they are all articles that we might contrive to do without. In tropical countries, however, such as Southern India and the adjacent islands, the case is very different; there the Cocoa-nut Palm furnishes the chief necessities of life, and its culture and the preparation of its various products afford employment to a large part of the population. Every part of the tree is put to some useful purpose. The outside rind or husk of the fruit yields the fibre from which the well-known cocoa-nut matting is manufactured. In order to obtain it the husks are soaked in salt water for six or twelve months, when the fibre is easily separated by beating, and is made up into a coarse kind of yarn called *covr*. In 1855 we imported 81,138 cwts. of this fibre.

Besides its use for matting, it is extensively employed in the manufacture of cordage, being greatly valued for ships' cables, and although these cables are rough to handle and not so neat-looking as those made of hemp, their greater elasticity renders them superior for some purposes. Other articles of minor importance are now made of this fibre, such as clothes- and other brushes, brooms, hats, &c.; and when curled and dyed it is used for stuffing cushions, mattresses, &c., as a substitute for horse-hair.

The next important product of the fruit is the oil procured by boiling and pressing the white kernel of the nut (albumen). It is liquid at the ordinary temperature in tropical countries, and while fresh is used in cookery; but in this country it is semi-solid, and has generally a somewhat rancid smell and taste. By pressure it is separated into two parts—one, called stearine, is solid, and is used in the manufacture of stearine candles; the other, being liquid, is burned in lamps. As an article of food the kernel is of great importance to the inhabitants of the tropics. In the Laccadives it forms the chief food, each person consuming four nuts per day, and the fluid, commonly called milk, which it contains, affords them an agreeable beverage. While young they yield a delicious substance resembling blanc-mange. The hard shells of the nut are made into spoons, drinking cups, lamps, &c.; reduced to charcoal and pulverised they afford an excellent tooth-powder, and very good lamp-black is made from them.

Amongst other products of this palm may be mentioned 'toddy,' which is obtained by the same process as that described under *Borassus flabelliformis*. When fermented it is intoxicating, and strong arrack is distilled from it, besides which it yields vinegar and 'jaggery' or sugar.

The leaves are greatly used for thatching houses, for plaiting into mats, baskets, hats, and similar articles; and from strips of the hard footstalk very neat combs for the hair are made. The unexpanded leaves cut out of the heart of the tree are used in the same way that we use cabbages. The brown fibrous network from the base of the leaves is substituted for sieves, and also made into fishermen's garments. And the extremely hard wood obtained from the outer portion of the trunk is used in the construction of both houses and their furniture. In this country, under the name of Porcupine wood, it is made into work-boxes, and other fancy articles. Finally, we may mention that the natives attribute various medicinal qualities to this palm. The flowers they employ as an astringent, the roots as a febrifuge, the milk in opthalmia, &c.

Few of the other species of this genus present particular features of interest. *C. butyracea*, a native of New Grenada, yields toddy, but the manner of extracting it is very different to the process employed in Eastern countries. The tree is cut down, and a long cavity excavated in its trunk near the top; in three days' time this cavity

is found to be full of toddy, which, it must be borne in mind, is the sap of the tree. Its seeds yield a semi-solid oil. *C. coronata*, a small Brazilian species not more than thirty feet high, has a pithy substance in the interior of its stem, which is used as food; its seeds also yield oil. The Cocoa-nut Palm is represented in Plate 7, fig. d. [A. S.]

**COCOTIER.** (Fr.) *Cocos nucifera*.

**COCRISTE.** (Fr.) *Rhinanthus major*.

**CODACANTHUS.** A small genus of Indian herbaceous plants, belonging to *Acanthaceæ*, and having the habit of *Campanula rapunculoides*. The drooping blue flowers are in compound one-sided racemes at the ends of the stem or branches; they are furnished with small bracts and bracteoles. The calyx is equally five-parted; the corolla has a short campanulate tube, and a five-cleft limb; there are only two included stamens owing to the non-development of the other pair; the style is free. The racemose inflorescence of this genus obviously separates it from the allied genera *Phlebophyllum* and *Endopogon*, which have their flowers in spikes. [W. C.]

**CODAZZIA.** A name given by Karsten and Trinius to *Delostoma integrifolium*.

**CODDA-PANNA.** *Bentlinckia Codda payna*.

**CODESO DEL PICO.** A name applied in Teneriffe to *Adenocarpus frankenwides*.

**CODIA.** A synonyme of *Pisonia*.

**CODIÆUM.** A genus of the spurgewort family found in the Moluccas, and the islands to the north of Australia. It is composed of shrubs which have much the appearance of *Aucuba*. They differ from *Ocrotia*, to which they are most nearly allied, in having very numerous stamens in the male flowers, and in the females being destitute of petals. Their beautiful painted leaves, which are shortly stalked and collected principally at the apex of the branches, vary much in form in the same species, being either linear or broadly oval, generally about six inches long, and quite smooth with entire margins. The green inconspicuous flowers are male and female on different racemes on the same plant: the males with a calyx of five divisions, five small petals, and very numerous stamens, and the females with a similar but smaller calyx, no petals, and a three-lobed ovary crowned with a trifid style. The fruit is a three-celled capsule about the size of a pea; each cell with a single seed.

*C. pictum* is a shrub often met with in stoves, where it is cultivated for the sake of its beautiful leaves, which are of a deep-red colour, or sometimes yellow mottled and variegated with green. In the Moluccas, its native country, it is cultivated about the houses, and used for fences. The inhabitants also decorate their triumphal arches with its leaves, and strew them about on occasions of festivity. The bark and root excite a burning sensation

in the mouth when chewed. This is the plant so often found in gardens under the names of *Ocrotia variegatum* and *Ocrotia pictum*. The two other known species are plants of very similar appearance. [A.A.B.]

**CODIUM.** The most highly organised of the siphonaceous division of green-spored *Algae* which occurs upon our coasts. The species resemble sponges. The frond is composed of branching filaments without any partitions, having on their lateral branchlets little cysts containing numberless minute zoospores. *C. tomentosum* has a more or less cylindrical or compressed forked green frond, and is found from the equator almost to the polar basin, but is scarcely found on the eastern coasts of North America, though common on the north. It extends also southward to Cape Horn, Australia, &c., without any essential change. [M. J. B.]

**CODLIN.** A variety of the Apple, *Pyrus Malus*.

**CODLINS AND CREAM.** *Epilobium hirsutum*.

**CODON.** A genus containing a single species from the Cape of Good Hope. It is an annual herb, covered over with white spines, and having alternate petiolate leaves and large flowers in terminal racemes. The calyx is ten to twelve-parted; the corolla is campanulate with as many lobes as the calyx, and like the sepals long and short alternately; there are ten to twelve stamens inserted at the base of the corolla tube; the ovary is sub-two-celled, free, and ovoid-acute with two parietal placentas, to which are attached numerous ovules. The capsule is surrounded by the persistent calyx, and surmounted by the style, and contains numerous angular tuberculated seeds; it dehisces loculicidally.

This genus has a very uncertain position. It has been most generally referred to *Solanaceæ* or to *Hydrophyllaceæ*, though by some to *Scrophulariaceæ* and even to *Boraginaceæ*. Its one-celled multiovular ovary, and parietal placentas separate it from *Boraginaceæ*. Its ten to twelve-lobed regular corolla, ten to twelve equal stamens, and one-celled ovary separate it from *Scrophulariaceæ*. Its habit and structure approach nearer to *Solanaceæ*, but it can scarcely be united to this order on account of its one-celled ovary and loculicidal dehiscence. In most characters, and in its whole habit, it is more nearly related to *Hydrophyllaceæ*, though differing remarkably from any other genus of the order. [W. C.]

**CODONANTHEMUM.** A genus of *Eriaceæ*, consisting of several species of heath-like plants, with ternate whorled or scattered leaves, and the flowers crowded together at the end of very short branches. It has a four-toothed calyx, and a hypogynous persistent corolla, both campanulate: the four stamens are inserted below the hypogynous disc, and have lateral exerted anthers: the ovary is one-celled with a single pendulous ovule, and the stig-

ma is obtuse. This genus scarcely differs from *Syndesmanthus*, except in having lateral and not terminal anthers. [W. C.]

**CODONANTHUS.** The name formerly

*rosten africana*. It is a branching tree of middling stature, with alternate oblong leaves narrowed at both ends, having entire margins and about six inches in length. Three or four white flowers grow in the axils of the leaves; the two exterior calyx leaves are large and heart-shaped, the others small and narrow; the corolla, which is bell-shaped, with a slightly recurved five-toothed margin, encloses five stamens, and an ovary surmounted by a bifid style, each of whose branches is furnished with a shield-shaped stigma. [A. A. B.]

**CODONOCALYX.** Small Brazilian hairy plants with dioecious flowers, constituting a genus of *Euphorbiaceæ*. The male flowers have a calyx with five deep divisions, a corolla of five overlapping segments, a disc of five free glands alternating with the petals, and ten stamens longer than the rest. [M. T. M.]

**CODONOCARPUS.** A genus of *Gyrotemoneæ* containing small shrubs from South Western Australia, with branched stems, alternate linear subulate leaves, and solitary axillary stalked flowers, which are dioecious, with a six or seven-lobed calyx and no petals. The male flowers have numerous sessile anthers; and the female flowers numerous carpels combined around a central column into a many-celled ovary; styles short recurved. The fruit is obovate, depressed, separating into numerous one-seeded cocci. [J. T. S.]

**CODONOPSIS.** A genus of *Campanulaceæ*, natives of the mountains of Northern India. They are glabrous herbs, often twining, with stalked crenate leaves whitish below, and axillary or terminal stalked flowers, which are yellow, bluish, or purple. Calyx-lobes five-lobed; corolla slightly fleshy, bell-shaped, five-lobed at the apex; stamens five; style with three stigmas; capsule hemi-spherical, three-celled, three-valved at the apex. [J. T. S.]

**CODONORCHIS**, literally Bell-orchis, in allusion to its campanulate flowers, is a small terrestrial genus, occurring in the southernmost parts of South America. The best known form, *C. Loxson*, a simple-stemmed plant with two three or four verticillate leaves near the base of a

supposed second form, called *C. Papp* is regarded by Hooker, fl., as a mere variety.

**CODONOSTIGMA** A genus of *Ericaceæ*, containing a single species from South Africa, a heath-like shrub with ternate

verticillate leaves, and flowers in terminal buds. It has a four-toothed campanulate calyx; a persistent globular cup-shaped corolla; four exserted stamens, attached below the hypogynous disc, with hairy

Its one-celled ovary allies it to the genus *Omphalocaryon*, but it has the calyx of *Cotlostigma*. [W. C.]

**CÆLANTHIUM.** A genus of *Caryophyllaceæ*, of the tribe *Molluginæ*, consisting of glabrous annuals from the Cape of Good Hope, with obovate stalked radical leaves in rosettes, while those of the stem are thread-like and verticillate, with fringed stipules. The stems are forked at the top; the flowers racemose with a funnel-shaped five-cleft calyx, having petaloid lobes; petals none; stamens five; stigmas three; capsule three-valved. [J. T. S.]

**CÆLEBOGYNE.** A genus of *Euphorbiaceæ*, found in the eastern tropical portion of New Holland, and represented by *C. ilicifolia*, a bush which in everything but its flowers is very like the common holly, or still more like the Japanese *Osmanthus*. The inconspicuous green flowers are male and female on different plants. The males, in the axils of the leaves, are arranged in short-bracted spikes, each bract toothed and supporting a number of

*Cælebogyne ilicifolia.*

flowers, which have a calyx of four divisions enclosing from four to eight stamens. In the female plant the flowers are arranged in a similar manner, or in little

with a three-lobed stigma, whose branches are large and lie flat on its summit. The fruit is a three-lobed capsule, about the size of a pea, with three cells, each of which contains one seed. The genus is nearly allied to *Concineba*, and differs only in the number of the calyx divisions.

This plant has excited much interest because it is said to ripen its seeds without the aid of pollen. Female plants (and females only) were sent to Kew by Allan Cunningham in 1829, where they flowered and perfected their seeds apparently without the aid of pollen. The circumstance was noticed by Mr. Smith, who made it the subject of a communication to the Linnean Society. This led to careful examinations by Klotzsch, Radtkofer, and A. Braun, besides other continental botanists. The former of these demonstrated from the formation of the seed that it contained no embryo but a bud; while the other two came to the opposite conclusion; and A. Braun made 'a most important observation, still unexplained by him, namely, that he found a pollen grain on the stigma of *Cocleboyyne*.' Naudin and Decaisne, in France, made experiments on *Hemp*, *Mercurialis*, and *Bryony*, as well as some other plants, and came to the conclusion that female plants of any of these, when sufficiently guarded against the accidental influence of pollen from the male flowers, produce perfectly ripe seeds. More lately, Regel in Russia has made extensive experiments on these plants, and affirms that no plant with evident sexual organs can produce perfect seeds without the aid of pollen. This is the opinion held by most botanists. [A. A. B.]

**CCELESTINA.** A genus of erect annual Mexican plants of the composite family, seldom more than two feet in height. Their leaves are opposite, shortly-stalked, and generally heart-shaped in form with notched margins, and often clad with short rough hairs. The blue flower-heads are about the size of a pea, and disposed in terminal corymbs. The florets are all tubular and perfect, and their pappus is cup-shaped and slightly toothed. In this latter character only does the genus differ from *Ageratum*, which has a pappus of from five to ten awned scales. The species are plants of little beauty. [A. A. B.]

**CCELIA.** A genus of terrestrial orchids with long grassy leaves, and dense spikes of rather small flowers supported by linear acuminate bracts. Three or four species are said to be known, but the genus has been little examined. *C. Baueriana*, with fragrant white flowers, from the West Indies, is that on which the genus was founded. It has a spurless lip, a three-winged ovary, and eight pollen masses without a gland.

**CCELOGLOSSUM.** An obscure genus of Indian terrestrial orchids with the habit and general structure of *Platanthera* or *Peristylus*, but with a concave lip, and a pair of adnate processes arising from the orifice of the spur. All have small green flowers.

**CCELOGYNE.** There occurs in the tropical and sub-tropical regions of Asia a race of pseudobulbous orchids, conspicuous for large coloured membranous flowers,

with converging and slightly-spreading sepals, petals of like nature but narrower, a great cucullate lip usually bearing fringes on its veins, and a broad membranous column. The pollen masses are four in number, waxy, and cohering by a granular substance; the stigma is prominent, deeply hollowed out (whence the name), and two-lobed. Most of the species are beautiful objects, and therefore favourites in cultivation. Some have tough persistent leaves and loose racemes of flowers; others have flowers peeping up from the soil in the absence of the leaves, in the same way as the crocuses of Europe; to the latter the name of *Pleione* has been given. Between forty and fifty species are known, the finest of which are *C. cristata*, with ivory-white flowers, whose velvety are fringed with yellow; *C. odoratissima*, unsurpassed for fragrance; and *C. præcox* (a *Pleione*), an Alpine plant, ornamenting with its large rich rose-coloured flowers the branches of oaks, at the elevation of 7,500 feet above the sea in lat. 30° N.

**CCELOSPERMOTS.** Hollow-seeded; when the seed, or seed-like fruit, is hemispherical, and excavated on the flat side, as in coriander.

**CENANTHIUM.** The receptacle of flowers in the inflorescence called a Capitulum; same as *Chinanthium*.

**CENOBIO.** The same as *Carcerulus*.

**CENOCLEADIA.** A name applied to the natural grafting which is so common in the beech in our own country and in many tropical trees. Both branches and roots, when growing so close together that there is no room for their proper development, become intimately united, and form a sort of network. Amongst herbaceous plants, as in *Asparagus*, *Hypocistis*, &c., union often takes place between two contiguous stems, which in this case are generally flatter than usual. Some cases of wide-flattened stems arise from this cause, but others apparently from the attack of insects. If two or more buds concur in the formation of such a stem, and they have different rates of growth, we have curled fasciated branches such as not uncommonly appear on the ash. Similar branches are produced in the elder by a species of *Acidium*. The roots of contiguous firs sometimes unite, so that when one of the trees is cut down, the stump still increases in diameter, in consequence of receiving nutriment from the tree with which it is united. [M. J. B.]

**COËNTRILHO.** A Brazilian name for *Xanthoxylum hiemale*.

**CERULEUS.** Blue; a pale indigo colour.

**CESIUS.** Lavender colour.

**COFFEA.** A genus of *Rubiaceæ* or *Cinchonaceæ*, composed of between fifty and sixty species, one of which yields the well-known article coffee. All are shrubs or small trees, seldom more than

twenty feet high, and inhabit the tropics of both hemispheres, the greatest number, however, being found in the Western. Their flowers have a small egg-shaped globular or top-shaped calyx, divided at the summit into four or five short teeth, and a tubular corolla, shaped like a funnel, with four or five spreading divisions; the stamens agreeing in number with the divisions of the corolla, and being either fixed to the top of its tube and protruded beyond it, or about half-way down on its inside, and entirely included within it. The fruit is a small fleshy berry, sometimes crowned by the remains of the calyx, and contains two seeds enclosed in a thin parchment-like shell, each seed being convex on the outside, but flat and marked by a longitudinal furrow on the inside.

The most interesting species is the Coffee shrub, *C. arabica*. This, when allowed to grow freely, will attain a height of twenty feet, with a stem three or four inches thick, but in a cultivated state it is seldom permitted to grow higher than ten or twelve feet, in order to facilitate the gathering of the berries. Its leaves are smooth and shining, and of a dark green on the upper surface,

*Coffea arabica*.

but paler beneath, about six inches long by two and a half wide, and of an oblong somewhat oval shape, with wavy edges, and terminated by a long narrow point. The flowers are produced in dense clusters at the bases of the leaves, and, being of a snowy white colour, they give the shrub a beautiful appearance, but are of ephemeral duration; their corolla is cut into five divisions, bearing the stamens fixed round the top of the tube, and protruded beyond it. They are succeeded by numerous little red fleshy berries resembling small cherries, each of which contains two of the seeds commonly called coffee.

At the present day the Coffee shrub is

cultivated throughout the tropics, but its native country is the mountainous regions at the extreme south-west point of Abyssinia, the word Coffee being derived from Caffa, the name of one of the provinces of that country. From Abyssinia the Coffee shrub was first introduced into Arabia by the Arabs, and cultivated in Yemen, or Arabia Felix as it was anciently called, and for upwards of two centuries Arabia supplied all the coffee then used. Towards the end of the seventeenth century, however, the Dutch succeeded in transporting it to Batavia, and from thence a plant was sent to the Botanic Garden at Amsterdam, where it was propagated, and in 1714 one was presented to Louis XIV. The credit of introducing the Coffee shrub into the Western Hemisphere is a disputed point. One story asserts that the French introduced it into Martinique in 1717; while, on the other hand, the Dutch are said to have previously taken it to Surinam. In either case, it is certain that we are indebted to the progeny of a single plant for all the coffee now imported from Brazil and the West Indies.

The early history of the use of coffee is enveloped in obscurity, and consequently there are many fables regarding its origin. According to the best accounts, the custom of drinking coffee originated with the Abyssinians, by whom the plant has been cultivated from time immemorial; and it was not introduced into Arabia until the early part of the fifteenth century, when a learned and pious Scheikh, named Djemal-eddin-Ebn-Abou-Alfaggar, returning from Abyssinia, brought a quantity of coffee with him to Aden, where it soon superseded the beverage made from the leaves of the kâf (*Cutha edulis*), and its use gradually spread over the rest of Arabia. It, however, met with great opposition from the priests, who classed it among the intoxicating beverages forbidden by the Koran, and therefore prohibited its use, but the most learned physicians having declared it to be harmless, the prohibition was removed. The European use of coffee dates from the middle of the sixteenth century, when it was introduced into Constantinople; and a century later, namely, in 1652, the first coffee-shop was established in London. Since then its use has become so general, that the consumption of this article in Europe and the United States is now estimated to be not far short of nine hundred million pounds, nearly half of which is the produce of Brazil. Ceylon, however, supplies the greatest portion of that consumed in this country. In 1858 the total quantity imported into the United Kingdom was 60,697,265 lbs., of which 35,208,932 lbs. was retained for home consumption, and the remainder re-exported. The import duty, being three pence per pound on raw, and four pence on roasted, yielded a revenue of 440,475*l*.

When ripe, the coffee berries are gathered, and the soft outer pulp removed by a machine called the pulper; they are then steeped in water for twenty-four hours to

remove all mucilaginous matter, after which they are carefully dried, and the parchment-like covering of the seeds removed by means of a mill and a winnowing machine. In Brazil, however, the berries as gathered are simply dried in the sun, and afterwards passed through a mill which crushes the shells and allows the separation of the seeds.

Before being used for the preparation of the well-known beverage, coffee undergoes the process of roasting. By this means it gains nearly one half in bulk, and loses about a fifth in weight; besides which its essential qualities are greatly changed, the heat causing the development of the volatile oil and peculiar acid to which the aroma and flavour are due. Coffee acts upon the brain as a stimulant, inciting it to increased activity, and producing sleeplessness; hence it is of great value as an antidote to narcotic poisons. It is also said to exert a soothing action upon the vascular system, preventing the too rapid waste in the tissues of the body, and by that means enabling it to support life upon a smaller quantity of food than would be otherwise required. These effects are due to the volatile oil, and also to the presence of a peculiar crystallisable nitrogenous principle termed *caffeine*; and it is not a little remarkable that closely allied, if not identical, principles exist in many similar beverages used by mankind, such for instance as tea, cocoa, Paraguay tea, and others. The leaves of the Coffee shrub likewise contain caffeine, and in the island of Sumatra the natives prefer an infusion of them to that of the berries. A patent has been taken out for the introduction of Coffee-tea into this country, but it has not been successful. A Javanese Coffee-plantation is shown in Plate 3. [A. S.]

**COFFEE.** *Coffea arabica*, the roasted seeds of which form the Coffee of the shops. —, **SWEDISH.** The seeds of *Astragalus beticus*.

**COFFEE-BEAN TREE.** *Gymnocladus canadensis*.

**COGWOOD.** *Ceanothus Chloroxylon*. —, **JAMAICA.** *Hernandia sonora*.

**COHESION.** The union or superficial incorporation of one organ with another.

**COHNIA.** An obscure genus of orchids, related to *Oncidium*, whose terete-leaved species it resembles in habit. The only knowledge of it is derived from a solitary specimen from Guatemala in the Vienna Herbarium, and from Reichenbach's description and figure in his *Xenia Orchidacea*.

**COHOSH.** An American name for *Actea* and *Leontice*. —, **BLUE.** *Leontice thaliotoides*.

**COHUNE OIL.** An oil obtained from the fruit of *Attalea Cohune*.

**COIGNASSIER.** (Fr.) *Orydonia vulgaris*.

**COIGNASSIER DU JAPON.** (Fr.) *Orydonia japonica*.

**COILOSTIGMA.** A genus of Cape Ericaceae, containing several heath-like shrubs, with ternate verticillate leaves, and flowers clustered at the end of the branches. The calyx has four divisions, generally equal, though sometimes with one larger than the others; the persistent corolla is small and ovate; the four stamens are inserted below the hypogynous disc, and have hairy anthers; the ovary has from two to four cells with a single ovule in each, and a cyathiform stigma. The members of this genus have the habit of *Simochilus*. They are separated from the allied genus *Codonanthemum* by the shape of the stigma, and from *Codonostigma* by the several-celled ovary. [W. C.]

**COIR.** Cocoa-nut fibre.

**COIX.** A genus of grasses belonging to the tribe *Phalarideae*. The flowers are monocious. The males grow in lax spikes; glumes two, membranaceous; pales two; stamens three. The females grow in two-flowered spikelets, the inferior flower being neuter with one pale, while the perfect flower has two fleshy pales, of which the superior is two-nerved. The best known species is *C. Lacryma*, commonly called Job's Tears, a native of the East Indies and Japan. This is frequently cultivated, but requires the shelter of a conservatory. The large round shining fruit have, when young, some resemblance to heavy drops of tears, hence the fanciful specific name. Its medicinal qualities are said to be strengthening and diuretic, and for these qualities it is sometimes used in the countries where it grows. [D. M.]

**COLA.** A genus of *Eurculiaceae*, containing eleven species. They are trees, with entire, lobed, or digitate leaves, and inhabit Tropical Africa. The flowers are unisexual or polygamous, in axillary clusters, and are destitute of a corolla. The calyx is coloured, and four- or five-cleft. The staminal column is often very short, bearing ten to twelve anthers, disposed in a single row, the anther-cells being parallel or superposed. The ovary is five to ten-celled, with numerous ovules. The fruit consists of four or five leathery or woody oblong capsules, ultimately splitting lengthwise. The seeds are large, numerous, obovoid, and exalbuminous, with thick sometimes two-parted cotyledons. [J. Br.]

*C. acuminata* grows about forty feet high, and bears pale yellow flowers spotted with purple; its leaves are about six or eight inches long, and pointed at both ends. Under the name of Cola, or Kola, or Goora nuts, the seeds of this tree are extensively used as a sort of condiment by the natives of western and central tropical Africa; and likewise by the negroes in the West Indies and Brazil, by whom the tree has been introduced into those countries. In Western Africa the trees grow mostly in the vicinity of the coast, and an exten-

sive trade is carried on in Cola nuts with the natives of the interior; the practice of eating Cola extending as far as Fezzan and Tripoli. A small piece of one of these seeds is chewed before each meal as a promoter of digestion; it is also supposed to improve the flavour of anything eaten after it, and even to render half-putrid water drinkable. There are several varieties of Cola nuts; the common kind has an astringent taste. [The Bitter Cola of Fernando Po is the produce of some guttiferous tree, as yet not identified.] Powdered Cola is applied to cuts. [A. S.]

**COLAX.** A small genus of epiphyllal orchids, near *Maxillaria*, under which name some have been published. It is especially remarkable for the condition of its caudicle, which seems to have no distinct gland, but consists of a thin waxy membrane gradually narrowing to the point where a gland usually occurs. *Maxillaria viridis* and *placantha* are the best known species.

**COLBERTIA.** A genus of *Dilleniaceae*, the type of which is a tree from tropical Asia with oblong or obovate shortly stalked serrated leaves, and large yellow flowers on one-flowered peduncles, several of which arise from the same scaly bud. It differs from *Dillenia* by the greater separation of its ovaries, which are generally fewer than in that genus. [J. T. S.]

**COLCHICUM.** The well-known Meadow Saffron, or, as it is erroneously called, Autumn Crocus. The genus appertains to *Melanthaceae*, and is known by its bell-shaped coloured perianth, with a long tube; six stamens inserted into the upper part of the tube; a three-celled ovary placed at the bottom of the tube, and surmounted by three long thread-shaped styles; and a three-celled capsule which bursts by as many openings. The appearance of the flower is so like that of the crocus, that it is frequently mistaken for it; but in the crocus there are three stamens only, and the ovary is placed below the tube of the perianth, not within it, as in the *Colchicum*; or, more correctly speaking, in the latter the ovary is free, while in the former it is united to the lower part of the tube of the perianth. *C. autumnale*, the Meadow Saffron, found wild in some parts of England, has a subterranean bulb-like stem, called a corm, from which in autumn the light purplish mottled flowers arise. The leaves do not appear till afterwards; they are fully developed in the following spring, in the shape of loose green sword-shaped blades, among which the ripened fruit may be found raised from below the surface of the ground by the lengthening of the flower-stalk.

The *Colchicum* is valued not only for its appearance, but more particularly for its medicinal properties. The dried corms and the seeds are the parts employed, the former have much of the appearance of tulip bulbs, but are not scaly like them, but solid in the interior. The active prin-

ciple is said to be an alkaline substance of a very poisonous nature called *colchicine*. *Colchicum* is principally used in medicine for the alleviation or cure of gonæ. In some cases its use is very beneficial, but, like other remedies, it has no claim to be considered infallible. It is acrid, sedative, and acts upon all the secreting organs, particularly the bowels and the kidneys. It is apt to cause undue depression, and in large doses acts as an irritant poison. Dr. Lindley relates the case of a woman who was poisoned by the sprouts of *Colchicum*, which had been thrown away in Covent Garden Market, and which she mistook for onions.

The Hermodactyls of the Arabians, formerly celebrated for soothing pains in the joints, are said by Dr. Royle to belong to *C. variegatum*. [M. T. M.]

**COLDENIA.** A genus of *Ehretiaceae*, consisting of herbs from India and Ceylon, with wedge-shaped stalked plicate serrated leaves, which are often more developed on one side of the mid-rib than on the other. Flowers small, white, axillary, solitary; calyx five-parted; corolla funnel-shaped. The nuts have a somewhat fleshy covering, and are rugose. *C. procumbens* is used in India for promoting supuration, for which purpose it is dried and powdered, and mixed with the seeds of the fennel-greek. [J. T. S.]

**COLD-SEEDS.** In the old materia medica the seeds of the cucumber, gourd, pumpkin, &c.

**COLEA.** A genus of *Croscantiaceae*, natives of Madagascar, Mauritius, and the neighbouring islands. They consist of glabrous shrubs or small trees, with impari-phinate bi- or many-jugate leaves. The calyx is sub-campanulate and five-toothed; the corolla is funnel-shaped, and the limb is cleft into five spreading lobes. The four didynamous stamens are inserted on the corolla, and have two-celled anthers. The fruit is oblong, fleshy, and indehiscent, with two cells containing many imbricated wingless seeds. [W. C.]

**COLEBROOKIA.** An East Indian genus of shrubs, belonging to the family of labiates. They are covered with reddish down. The flowers are clustered, of a white colour, with a bell-shaped equally five-parted calyx, the segments of which are feathery, and whose tube becomes confluent with the ripe fruits; a short-limbed corolla divided into four nearly equal divisions, the upper lobe notched, and four stamens equidistant one from the other; the anthers with two parallel cells. *C. oppositifolia* and *C. ternifolia* are in cultivation as greenhouse shrubs. [M. T. M.]

**COLEONEMA.** A beautiful genus of Cape *Rutaceae*, related to *Diosma*, and consisting of evergreen shrubs with sharp linear leaves, and white flowers, consisting of five petals attached to the base of a five-lobed disc, which is adherent to the tube of the calyx, and having a broad stalk or claw which is furrowed

longitudinally. There are ten stamens, five sterile, concealed in the furrows of the claws of the petals and adherent to their base, and five fertile, opposite to the lobes of the disc, longer than the sterile ones, and having their anthers tipped with a minute sessile gland. The fruit is a capsule of five carpels, each provided with a small horn-like process at the top and opening by two valves. *C. album* is the best known species. [M. T. M.]

**COLEOPHORA.** The name given to a tree of the Sapine family found in Brazil, the leaves of which are not known. From the little scaly buds, which are scattered over the trunk of the tree, the flowers proceed. They are small, yellow and brown, and borne on short racemes. The tubular calyx has a four or five-toothed border fringed with hairs, and inside of it, and surrounding the stalked ovary, is a little four-toothed petal-like cup, about half the length of the calyx tube. The stalked ovary, surrounded by the petal-like cup, serves to distinguish the genus. [A. A. B.]

**COLEOPHYLL, or COLEOPTILE.** The first leaf which follows the cotyledon in eudogens, and ensheaths the succeeding leaves.

**COLEORHIZA;** The sheath formed at the base of an endogenous embryo, where it is pierced by the true radicle.

**COLEOSTYLIS.** Herbaceous plants covered with glandular hairs, natives of New Holland, and closely allied to *Stylidium*, but distinguishable from it by the following characters:—The limb of the corolla is divided into five segments, four of like form, stalked; the fifth or lip is unlike, jointed to the tube of the corolla, stalked, its blade boat-shaped, notched at the point or prolonged; and the column, which consists of the stamens and style united together, is shorter than the lip, erect, and passing through a kind of sheath. [M. T. M.]

**COLESFED, or COLLARD.** The Rape, *Brassica Napus*.

**COLESULA.** The small bag which contains the spore-case of Liverworts.

**COLEWORT, or COLLET.** The Cabbage, *Brassica oleracea*.

**COLEUS.** A considerable genus of Labiate, found in Asia and Africa. It consists of herbs, annual or sometimes perennial, rarely shrubs. The flowers are in loose or dense verticillasters. The calyx is ovate-campanulate, bending back when in fruit, the limb five-toothed or bilabiate. The corolla-tube is longer than the calyx, the limb bilabiate with the upper lip obtusely three to four-cleft, and the lower entire, lengthened, and concave, often curved and enclosing the four stamens. The style is bifid with imbricate lobes. The nectary is compressed and smooth. [*C. Blumei* and *C. Verschaffeltii* have yielded in gardens some beautiful hybrid forms, many of them with highly coloured yellow and red leaves.] [W. C.]

**COLICODENDRON.** A genus of *Cappariaceae*, consisting of tropical American trees or shrubs, covered with small star-shaped hairs, and having clusters of flowers, with a cup-shaped calyx, divided into four or five segments, provided internally and at their base with a petaloid scale. The four or five petals are inserted on to the calyx; the stamens are from eight to twenty, inserted on a stalk, and united at the base into a shallow cup; the ovary is also on a long stalk. The fruit is a roundish or elongated berry, knotted and containing several kidney-shaped seeds. The genus possesses an acrid principle, which, according to Martius, is so potent in *C. Yeo* as to be dangerous to mules and horses. [M. T. M.]

**COLIC ROOT.** *Aletris farinosa*.

**COLIGNONTA.** A genus of Peruvian herbs or undershrubs belonging to the order *Nyctaginaceae*, and having flowers arranged in an umbellate manner, surrounded by deciduous bracts. The perianth is coloured, bell-shaped, with a five-cleft limb from which the five stamens protrude; the style is simple; the stigma is fringed. The fruit is hardened, pentagonal, crowned by the upper part of the perianth. [M. T. M.]

**COLLABIUM nebulosum.** A terrestrial orchid, with a slender creeping rhizome, known only by a brief description of Blume, who says it has distant stalked membranous radical leaves clouded with purple, and small nodding spiked flowers, whose sepals are reflexed.

**COLLANIA.** A genus of amaryllids allied to *Alstromeria*, from which it differs in having a pulpy fruit, and in 'the great prominence of the operculum of the germen, making it at least half superior instead of inferior.' The species are natives of Peru, and are very ornamental plants. They have rigid erect stems curved at the summit, bearing simple rigid leaves, and a pendulous umbel of flowers, of which the six-leaved perianth is tube-formed and not at all spreading. *C. dulcis* has stems about a foot high, erect with a little tortuosity but not prehensile, clothed with oblong obtuse glaucous leaves, which are narrowed at the base, and terminating in a four-flowered umbel of cylindraceous purple flowers tipped with green, the three petaloid segments longer and bright green. This plant is called 'Campanillas coloradas' in its native country, and the fruit is sweet and agreeable to the taste, and much sought by children, the seeds being enveloped in a reddish gelatinous substance. *C. andimarcana* is a much larger plant, with a stem terminating in a fine umbel of leafy racemes of large pendulous sub-cylindraceous flowers, upwards of two inches long, of which the sepals are orange red tipped with black, and the petals yellow tipped with green. The name *Collantia* has also been applied to

another genus of the same order, now called *Urceolina*. [T. M.]

**COLLAR.** The ring upon the stipe of an agave; see also Collum.

**COLLARE.** The ligule, or transverse membrane that stands in grasses at the junction of the blade and sheath of the leaf.

**COLLATERAL.** Standing side by side.

**COLLECTORS.** The hairs found on the style of such plants as the *Campanula*, and which collect or brush out the pollen from the anthers.

**COLLEMACEÆ.** A natural order of lichens, distinguished principally by their gelatinous substance and the green globules or gonidia, which are so distinctive a mark of lichens in general, forming necklace-like threads. They are found in various parts of the world, and though in general attracting little notice when dry, a few hours rain swells them out and exhibits often extremely beautiful forms. One of the most curious genera is *Myrianthum*, which occurs in the southern part of England, Algeria, Australia, and the United States, on the trunks of living trees, and is remarkable for the high development of the sacs or asci in which the sporidia are contained. These plants have been considered as a distinct group from lichens, but such a notion is at present received with little favour. The resemblance of the young plant to *Noctua* is so striking, both in appearance and structure, that the one has been supposed to be the infant state of the other, but without sufficient grounds. The species grow on trees, rocks, and the bare ground, and, if *Lichina* be included, in situations exposed to frequent immersion in the sea. One at least of the species has a very fetid smell. A species of *Noctua*, found in running streams in China, is used as an ingredient in soup. [M. J. B.]

**COLLENCHYMA.** The cellular matter in which the pollen is generated; usually absorbed, but remaining and assuming a definite form in some plants, as in orchids, or delicate threads, as in *Eriothera*.

**COLLETIA.** A genus of American *Ehmanniaceae* inhabiting Chili, Peru, and Mexico. They are much-branched shrubs, scantily furnished with minute leaves, and having spines which stand at right angles with the stem in alternate pairs. The flowers, which are yellowish or white, are either solitary or in tufts in the axils of the leaves, or rise from beneath the base of the spines. Two or three species are known in gardens. [C. A. J.]

**COLLINSIA.** A genus of dwarf annuals belonging to *Scrophulariaceae*, all indigenous to North America, chiefly of the north-western regions, and including several showy border plants. Its most important features are a deeply five-cleft calyx; a two-lipped irregular corolla, with the tube bulging at the base on the upper side, the upper lip two-cleft with its lobes

erect, the lower lip three-cleft, the middle lobe forming a pouch-like cavity in which the stamens and style are enclosed; and a globose two-celled many-seeded capsule. All the species are of branching habit, and furnished with opposite leaves, and flowers in erect whorled racemes. *C. bicolor*, one of the best known, grows twice to eighteen inches high, and has sessile ovate-lanceolate toothed leaves, either opposite or in threes, and strongly nerved, the flowers, which are in whorls of five or six blossoms, having their upper lip very pale lilac or whitish, and the lower one deep lilac-purple. *C. heterophylla* has rather larger and deeper coloured flowers, with the calyx clothed with coarse hairs, and the lower leaves three-lobed and stalked. In *C. multicolor* the upper lip has a broad white central spot speckled with crimson, and the leaves beneath the whorls are tinged with purple. These characters are, however, somewhat inconstant under cultivation, and it is doubtful whether this plant, as well as *C. heterophylla*, may not be a mere variety of *C. bicolor*. *C. verna* is a very pretty little species scarcely known in this country, though the first discovered; it differs from the preceding in its flowers having longer pedicels, as well as in their colour, which is pure white in the upper lip, and blue, of variable intensity, in the lower one. *C. grandiflora*, a species common in our gardens, is sometimes confounded with *verna*, but has shorter pedicels, and the upper lip of flower is lilac. [W. T.]

**COLLINSONIA.** A genus of *Labiata*, containing a few species of strong-scented perennial herbs, natives of North America. They have large ovate leaves, and yellowish flowers on slender pedicels in loose and panicled terminal racemes. The calyx is ovate and two-lipped, with the upper lip truncate and three-toothed, and the lower two-toothed; it is declined in fruit. The corolla is elongated, expanded at the throat, and somewhat two-lipped, with the four upper lobes nearly equal, but the lower larger, longer and pendent, toothed or lacerate-fringed. There are two, sometimes four, much exerted diverging stamens, with divergent anther cells; the apex of the style is subequally bifid; and the nodule is smooth. [W. O.]

**COLLINUS.** Growing on low hills.

**COLLOMIA.** A small genus of *Polemoniaceae*, having a five-cleft campanulate calyx, a corolla with salver-shaped limb and slender tube, five stamens inserted in the middle of the tube, and a three-celled capsule, each cell containing one or two seeds. It is nearly related to *Gilia*, from which it differs chiefly in habit, colour of flowers, and form of corolla. The species are all dwarf annuals with red or buff-coloured flowers, natives of the Western Hemisphere, and chiefly of California. With one or two exceptions they are quite devoid of interest as ornamental plants, their flowers being small and without effect. C

*coodesia* or *Cavanillesii* grows nearly a foot high, with a branched stem, linear-lanceolate leaves, and terminal clusters of brick-red flowers each nearly half an inch across, the tube and under side of corolla being a buff-yellow, and the calyx glandular. *C. grandiflora*, the only other species worth cultivating, is taller, and more robust, with shining lanceolate leaves, and large mauve-coloured flowers. The species have no known properties, but their seeds are remarkable for the quantity of mucus existing in their testa or outer covering—whence the name of the genus from *kolla*, glue,—which gives rise, under certain conditions, to a singular and interesting phenomenon. When these seeds are thrown into water the mucous matter is dissolved and forms a cloud around them. [Dr. As. Gray states that this mucilage consists of innumerable and most delicate diaphanous tubes, which lengthen wonderfully when wetted. The spiral thread which they contain (on which account they were confounded with spiral vessels, and which uncoils as the tube softens or dissolves into jelly) is wanting in *C. gracilis*. In this the mucilage cells are beneath a more or less evident pellicle or epidermis, which is not obvious in the typical species, composed of fragile tubular cells which are thrown off when the former develop, and protrude under moisture.] [W. T.]

**COLLOPHORA.** The name of a little-known Brazilian tree, mentioned by Von Martius, as abounding in a milky juice furnishing caoutchouc. The genus belongs to the *Apocynaceæ*. It has a salver-shaped corolla, without scales in the throat of its tube; and the stigma is cylindrical. The fruit is a berry containing several seeds embedded in pulp. [M. T. M.]

**COLLUM.** The point of junction between the radicle and plumule; the point of departure of the ascending and descending axes, that is to say, of the root and stem, which is often called the collar. Also the lengthened orifice of the ostiolum of a lichen; *Colliform* is sometimes applied to an ostiolum, whose orifice is lengthened into a neck.

**COLLYBIA.** A sub-genus of white-spored agarics with the outer coat of the stem cartilaginous, the margin of the pileus at first involute, and the gills not decurrent. *Agaricus fusus*, which is not uncommon at the foot of old oaks, growing in dense tufts of a more or less decided rufous tint, though too tough for stewing, is excellent when pickled. *A. saculentus* also, which, though small, is brought abundantly into the German markets under the name of *Nagelachswämme*, belongs to the same sub-genus. One of the best known species of the group is *A. velutipes*, which grows on almost every decayed tree, conspicuous for its velvety stem and rich yellow shining pileus. Few plants are more patient of cold than this, for the severe Christmas frost of 1880 did not destroy it, specimens after the thaw being as vigorous as ever. [M. J. B.]

**COLOCASIA.** A genus of *Araceæ*, very closely allied to *Caladium*, but differing from it in the spadix having a club-shaped or pointed top destitute of stamens. The middle portion of the spadix is provided with stamens, above and below, which latter are rudimentary organs. The anthers are two-celled, opening by pores, and having a broad wedge-shaped connective. The ovaries, at the base of the spadix, are one-celled, with six erect ovules. The plants are Indian herbs, with tuberous or stem-like rootstocks, and pettate leaves. *C. antiquorum*, the *Arum Colocasia* of Linneus, is cultivated in most tropical countries, Egypt, India, &c., for the sake of its leaves, which when uncooked are acrid, but by boiling, the water being changed, lose their acridity, and may be eaten as spinach. *C. indica* is cultivated in Brazil for its esculent stems and small pendulous tubers. *C. esculenta*, *C. macrorhiza*, and many varieties of these species, are cultivated in the Sandwich Islands under the name of *Taro*; and their rootstocks being filled with starch, furnish a staple article of diet among the natives. The leaves are likewise used as a vegetable. [M. T. M.]

**COLOCYNTH.** *Citrullus* or *Cucumis Colocynthis*. — HIMALAYAN. *Citrullus* or *Cucumis Pseudo-colocynthis*.

**COLOMBINE PLUMEUSE.** (Fr.) *Thalictrum aquilegifolium*.

**COLOQUINTE.** (Fr.) *Citrullus Colocynthis*.

**COLOMBO** or **CALOMBA.** The Calumba root, *Jateorrhiza* (formerly *Cocculus*) *palmata*. — AMERICAN. *Fraxea Walleri*.

**COLOUR** (adj. **COLOURED**, **COLORATED**). Any colour except green. In technical botany white is regarded as a colour, and green is not.

**COLPENCHYMA.** Sinuous cellular tissue

**COLPOON TREE.** *Cassine Colpoon*.

**COLQUHOUNIA.** A genus of *Labiata*, containing three species of climbing or erect shrubs, natives of India, with petiolate ovate acuminate leaves, and scarlet flowers scattered in axillary verticillasters or crowded in a terminal spike, and having small bracts. The calyx is tubular, campanulate, ten-nerved, and unequally five-toothed; the corolla tube is longer than the calyx, its throat dilated, and its limb bilabiate, with the upper lip entire, and the lower with three small ovate lobes; the stamens are covered by the galea or helmet; the apex of the style is subequally bifid, with subulate lobes; the nucule is oblong, dry and smooth, with a membranaceous apex. [W. C.]

**COLTSFOOT.** The common name for *Tussilago*. — SWEET. An American name for *Nardoena*.

**COLUBRINA.** Snake-wood, so called from the twisted wood of one species, which inhabits the forests of Martinique. A family of plants belonging to the order

**Rhamnaceæ**, comprising small trees and shrubs, some of which are climbing, natives of South America and the warmer regions of Asia and Africa. They are closely allied to *Coccolobus*, but possess no properties which render them worthy of cultivation. [C. A. J.]

**COLUM.** An obsolete term for the placenta.

**COLUMBINE.** The common name for *Aquilegia*.

**COLUMELLA.** A little column; the firm centre of the spore-case of an urimoss, from which the spores separate. The long axis round which the parts of a fruit are united; in reality, the thickened growing point. A slender axis, over which the spore-cases of such ferns as *Trichomanes* are arranged.

**COLUMELLIA.** A genus of epigynous exogens having a monopetalous corolla, the structure of which, and especially of the anthers, is so remarkable that it has been separated as a distinct order under the name of *Columelliaceæ*. It consists of a few evergreen shrubs or trees, natives of Mexico and Peru, having opposite entire or slightly serrated leaves, and small yellow flowers. The calyx is superior, five-cleft; the corolla five-lobed; the stamens two only, attached to the tube of the corolla, and the anthers are as usual only two-celled, but each cell is elongated, more so than in any other plants comparatively with the size of the anther, but being doubled and redoubled on themselves they form a globular mass. The author of *C. oblonga* has the shortest cells of any of the species. The ovary is two-celled, each cell containing numerous ovules, and the seed has a large quantity of albumen. The station of *Columelliaceæ* in the natural system is near *Styliadaceæ*, the stamens in the latter being only two, although differently attached. (See *Ann. and Mag. Nat. Hist.* ser. 3. i. 109.) [B. C.]

**COLUMELLIACEÆ.** *Columellia*, which consists of two or perhaps three species from the Andes of America, having no immediate affinity with any of the orders with which it has been compared, has therefore been considered as forming a family of itself. It consists of evergreen shrubs or small trees with opposite serrate leaves without stipules; a superior five-cleft calyx; a five-lobed spreading corolla bearing in its short tube two stamens, each with three waved anthers. The ovary is inferior, two-celled, with numerous ovules; the fruit capsular; the seeds numerous, with the embryo in the axis of a fleshy albumen. These characters, as well as the habit, remove the genus from the generality of *Monopetalæ*, and indicate several points of connection with *Saxifragæ* and their allies, amongst which *Columellia* may possibly take its place as a gamopetalous form.

**COLUMN.** The combined stamens and

styles forming a solid central body, as in orchids.

**COLUMNARIS.** Having the form of a column, as the stamens of a mallow.

**COLUMNEA.** A genus of erect or climbing slender herbaceous plants or undershrubs, with opposite fleshy and hairy leaves, and solitary or crowded axillary peduncles bearing scarlet flowers. They are natives of tropical America, and belong to the order of *Gesneraceæ*. The calyx is free and five-parted. The corolla is tubular, with the limb two-lipped, the upper one entire, erect or overarching, the lower trifid and patent; the four didynamous stamens are inserted in the tube of the corolla, and with them the rudiment of a fifth; the ovate anthers have two cells. The one-celled ovary is free, surrounded by a five-lobed disc, and contains two two-lobed parietal placentas with anatropal ovules. The fruit is a berry containing many obovate seeds, and two fleshy placentas. The genus is near to *Besleria*, differing chiefly in the form of the corolla. [W. C.]

**COLURIA.** A genus of the rose family, very nearly allied to *Geum*, but differing in the styles being jointed and falling from the achenes when mature, while in *Geum* they remain attached and become feathery. *C. geoides*, the only species of the genus, is a plant about six inches high with pinnatifid leaves having cut segments, and a peduncle bearing one to three little yellow flowers. Altogether it bears much resemblance to the silver-weed, *Potentilla anserina*, but its leaves although pubescent are not clothed with silvery hairs. It is found on the less elevated mountains in Siberia, growing in rocky places. [A. A. B.]

**COLUTEA.** The technical name of a genus of *Leguminosæ* consisting of certain shrubs, indigenous to the south of Europe and the Mediterranean region in general, and especially characterised by having, with the ordinary papilionaceous flowers, membranous bladder-like pods. The leaflets of *C. arborescens* and other species have purgative properties like those of senna, and are sometimes mixed with senna leaves. The distended pods, when pressed suddenly, burst with a loud noise, hence the common name, Bladder-senna. Two or three species are cultivated as deciduous plants in this country, but they seem to be more abundantly used on the Continent than with us. *C. arborescens* is said to grow on the crater of Vesuvius, where there is little other vegetation. [M. T. M.]

**COLVILLEA.** The name given to a tree of Madagascar belonging to the leguminous family. The genus is nearly related to *Casalpinia*, but is readily distinguished by the form of its calyx, which is two-lipped, the upper lip convex and four-toothed, and the lower linear in form and entire. *C. racemosa* is a beautiful tree, which attains a height of forty or fifty feet, and is furnished with elegant fern-like twicely-pinnate leaves about three feet long; these

are made up of from twenty to thirty pairs of pinnae, each pinna with a like number of opposite leaflets, which are nearly linear in form, and about half an inch long. The beautiful scarlet flowers are in dense racemes, which arise from the axils of the upper leaves, and are either simple or branched, and about a foot and a half in length. The calyx, like the petals, is of a scarlet colour; the petals are five in number, the standard the smallest and nearly hidden by the others, the two oblong wings next in size, and the two free petals, which form the keel, the largest; the ten free stamens are of unequal length. The pod is straight, about six inches long, containing a number of seeds. The genus bears the name of Sir Charles Colville, once governor of the Mauritius. [A. A. B.]

**COLZA.** (Fr.) *Brassica Napus oleifera*.

**COMA** (adj. **COMOSE**). The hairs at the end of some seeds; the empty leaves or bracts at the end of the spike of such flowers as those of the pine-apple.

**COMANDRA.** The generic name of plants belonging to the sandalwood order; having the calyx adherent to the seed-vessel, its upper part with an adherent disk whose border is five-lobed, on which the stamens are inserted between its lobes and opposite those of the calyx, the anthers being connected with the calyx by a tuft of hair-like threads. The fruit is nut-like and filled with the globular seed. The name is derived from the Greek words signifying 'hair' and 'stamen,' indicating a character above mentioned. The plants are low perennials with herbaceous stems springing from a woody base; the leaves alternate, stalkless, oblong; flowers greenish-white in small clusters. One species, *C. umbellata*, is common in North America, and attaches itself as a parasite to the roots of trees. [G. D.]

**COMAROSTAPHYLIS.** A genus of *Ericaceae*, containing fourteen species of small trees or shrubs, with the habit of *Arbutus*, natives of Mexico and Guatemala. They have coriaceous oblong evergreen leaves, and flowers in terminal bracteate racemes or panicles. The hypogynous calyx is five-parted; the corolla is inserted on the calyx, is campanulate, enlarged below, and has the limb five-lobed. The ten stamens are inserted on the base of the calyx; the filaments are short, and the anthers oval and compressed. The ovary is placed on a ten-angled hypogynous disc, and has five cells, with a single ovule in each. The style is simple, and the stigma obscurely five-toothed. The drupe is globose and fleshy, containing a single stone (pyrena), which has five rarely more cells, with a single seed in each. [W. C.]

**COMARUM.** A Rosaceous marsh herb, with a stout creeping stem, rather large and handsome leaves composed of seven, five, or three deeply-serrated leaflets, and slightly-branched panicles of dingy-purple

flowers. The fruit somewhat resembles that of the strawberry, but is spongy instead of juicy, and does not fall off when ripe. It is of frequent occurrence in marshes and boggy meadows in most parts of England, and extends over a great part of Europe and North America. The roots and stems have been used to dye wool of a dirty-red colour, and are sufficiently astringent to be employed in tanning. In some parts of Scotland the fruits are called Cow-berries, on account, it is said, of their being used to rub the inside of milk-pails for the purpose of thickening milk. The Marsh Cinquefoil, *C. palustre*, is rarely cultivated, though Gerard says with some pride that he brought some plants from Bourne Ponds, half a mile from Colchester, for his garden, and that they there flourished and prospered well. French Comarut; German Fünfblatt. [C. A. J.]

**COMBESIA.** A genus proposed by Richard for an Abyssinian species of *Tilia*, having pentamerous flowers, and a gamopetalous corolla. One or two other species have since been referred to it; but there are no sufficient grounds for regarding it as a distinct genus. *T. (C.) pharnacoides*, upon which the genus was founded, occurs also in S. Africa, and the Himalayas. [J. Br.]

**COMBIMATE-VEBOSE.** When the lateral veins of a leaf unite before they reach the margin.

**COMBRETACEÆ** (*Myrobales*). A natural order of polypetalous calyciflorous dicotyledons, belonging to Lindley's myrtal alliance. Trees or shrubs, with alternate or opposite entire leaves having no stipules. Sometimes the flowers are imperfect, some having stamens only, others pistils only, and occasionally the petals are wanting. Calyx adherent, its limb four to five-lobed, falling off. Petals arising from the orifice of the calyx, alternate with the lobes. Stamens often eight or ten. Ovary one-celled, with two to four suspended ovules. Fruit succulent or dry, one-celled, and one-seeded. Seeds without albumen; cotyledons of the embryo rolled up. Natives of the tropical parts of Asia, Africa, and America. The plants of the order have astringent qualities; some are cultivated for ornament, others yield timber. The astringent fruit, known by the name of Myrobalan, is produced by *Terminalia Bellerica* and *T. Chebula*. The bark of *Bucida Buceras* is used for tanning. There are twenty-three known genera, and upwards of 200 species. Illustrative genera: *Terminalia*, *Combretum*, *Gyrocarpus*. [J. H. B.]

**COMBRETUM.** The typical genus of *Combretaceæ*, inhabiting tropical regions of both hemispheres, and consisting of trees or shrubs, often trailing or climbing by the indurated leaf-stalks, which are persistent and act as hooks to support the plant. The leaves are opposite, rarely alternate, entire, exstipulate. The flowers, which grow in spikes, axillary or sometimes terminal, solitary or arranged in

a panicle, are polygamous; calyx-tube adhering to the ovary, above which it is constricted, the limb bell-shaped; petals four; stamens eight. The fruit is leathery, with four membranous wings, indehiscent and one-seeded by the abortion of several of the ovules. Many of the species are very handsome. [J. T. B.]

**COMB-SHAPED.** The same as Pectinate.

**COMESPERMA.** A genus of *Polygalaceae*, consisting of erect or twining plants found in Australia and Tasmania, and numbering about twenty species. It is nearly related to the South American genus *Catocoma*, but differs in the corolla being composed of three united petals, instead of five. The stems, which are not much thicker than a crow-quill, are furnished with alternate leaves, mostly linear in form. The flowers, disposed in axillary or terminal racemes, either yellow, white, blue or purple, the three latter colours sometimes found in the same species, as they are in our own common milkwort, *Polygala vulgaris*, to whose flowers those of the plants of this genus bear much resemblance, but are generally larger. The calyx is five-lobed; the corolla three-lobed, the middle lobe largest; the stamens eight; the ovary two-celled, crowned with a curved style. The fruit is a wedge-shaped capsule with two seeds, each furnished with a tuft of silky hairs. This latter circumstance gives rise to the name of the genus.

*C. volubilis*, the Blue-creeper of Tasmania, is a graceful little plant, twining among other bushes and covering them with its great abundance of beautiful blue flowers. Its thin twining stems are furnished with leaves which are between linear and lance-shaped in form. This plant grows in various parts of Australia, as well as in Tasmania, and is universally admired. It has been in cultivation in England under the name *Comesperma gracilis*. [A. A. B.]

**COMFREY.** *Symphytum officinale*.

**COMIN.** (Fr.) *Ervum Bretilia*.

**COMMELYNACEÆ.** (*Spiderworts*.) A natural order of hypogynous monocotyledons, belonging to Lindley's xyridal alliance. Herbs with flat leaves, usually sheathing at the base. Outer perianth (calyx) of three parts, herbaceous; inner (corolla) also of three, coloured; stamens six or three, the anthers opening on the side next the pistil. Ovary three-celled with a central placenta; style one. Fruit a two to three-celled capsule, opening by two or three valves, which bear the dissepiments (partitions) on the middle; seeds with a linear hilum; embryo pulley-shaped. Natives of the East and West Indies, New Holland, and Africa. A few are found in North America, but none in Northern Asia or Europe. The underground stems of many of the plants yield starch, and are used for food. The filaments of the *Tradescantias*

have jointed hairs, in which a granular movement is seen under the microscope. There are sixteen known genera, and 380 species. The best known are *Commelyna*, *Tradescantia*, and *Cyanotis*. [J. H. B.]

**COMMELYNA.** The typical genus of the order of spiderworts, distinguished by having usually three petals, dropping early, one of the three different in form from the others, or wanting; the filaments or stalks of the anthers smooth and naked; the style or appendage on the seed vessel thread-like, and entire at the end. The species are herbs, natives of tropical and Northern America, East India, and New Holland, having ovate or lance-shaped leaves, and the flowers in groups, either issuing from an involucre or sheath-like body, or destitute of such covering, the former constituting *Commelyna* proper, the latter *Anilema*. The genus was named in honour of J. and G. Commelyn, well-known Dutch botanists. The species are numerous, and several have been long known in our collections. They require various modes of treatment, some being hardy, others requiring a high temperature. *C. celestis*, notable for the delicate blue of the flower, has oblong lanceolate leaves, and the sheaths ciliated; it is a half hardy species, which under proper treatment displays a succession of azure flowers from July to September. One of more recent introduction is *C. scabra*, a half hardy perennial from Northern Mexico, having straggling reddish stems, the leaves lance-shaped, waved and hard at the margin, and the flowers of a dull purple brown. Dr. Lindley, in his *Vegetable Kingdom*, states that 'the fleshy rhizomes of *C. celestis*, *tuberosa*, *angustifolia*, and *striata*, contain a good deal of starch mixed with mucilage, and are therefore fit for food when cooked. The Chinese employ those of *C. medica* as a remedy in cough,' &c. [G.D.]

**COMMIA.** A genus from Cochinchina, so named by Loureiro, but now referred to *Escocaria agallocha*, one of the *Euphorbiaceae*. Loureiro describes it as a tree from which a white tenacious gum exudes, said to be of a purgative and emetic nature, and valuable in dropsy, but requiring careful administration. The leaves are stalked, lance-shaped, entire and smooth. The inconspicuous flowers are male and female on different plants: the males in short axillary bracted spikes, having neither calyx nor corolla, and the stamens united into a column which bears on its summit a number of anthers; the females in terminal racemes having a three-leaved calyx enclosing a three-lobed ovary, crowned by three short recurved styles. The fruit a three-celled capsule with three seeds. [A. A. B.]

**COMMISSURE.** The face by which two carpels come together or cohere, as in umbellifers.

**COMMON PETIOLE.** The first and principal leaf-stalk in compound leaves; the secondary petioles are called partial.

**COMOLIA.** A genus of *Melastomaceae*, consisting of Brazilian trees or shrubs, with four-sided branches and obovate three-nerved leaves clothed with adpressed hairs; flowers axillary, solitary, sessile, white; tube of calyx adhering to the base of ovary, its limb four-lobed; petals four; anthers one-celled curved; ovary glabrous; capsule two-celled. [J. T. B.]

**COMPAGNON BLANC.** (Fr.) *Lychnis dioica*.

**COMPARETTIA.** A small genus of epiphytal orchids inhabiting tropical America. Four species are known, all with small pseudobulbs, coriaceous leaves, and gracefully bending racemes of long spurred rose-coloured purple or scarlet flowers.

**COMPASS PLANT.** *Silphium laciniatum*, which is said to present the faces of its leaves uniformly north and south.

**COMPLEXUS.** Tissue: *C. cellulosus*, cellular tissue; *C. membranaceus*, the thin membrane, which is the foundation of all tissue—elementary membrane; *C. tubularis* tubular tissue, or woody fibre; *C. utricularis*, angular cellular tissue; *C. vascularis*, spiral vessels, properly so-called: often, however, extended to all sorts of tubes with markings on the side, thus losing precision, and with it its value as a scientific term.

**COMPLICATE.** Folded up upon itself.

**COMPOSITE.** The more familiar name of the *Asteraceae*, a large natural order of gamopetalous alicyclic dicotyledons belonging to Lindley's campanal alliance, consisting of herbs and shrubs with alternate or opposite leaves having no stipules; the stamens and pistils either in the same or in separate flowers, which are collected into a head on a common receptacle (hence the name Composite or compound flowers), and surrounded by a set of floral leaves or bracts, called an involucre. The fruit is single-seeded, crowned with the limb of the calyx. The plants are found in all parts of the world, in warm countries sometimes assuming arborescent forms. They were included by Linneus in his class *Syngenesia*. The properties of the order are various; but bitterness seems to prevail in it, and this is accompanied with tonic, stimulant, aromatic, and sometimes even narcotic qualities. *Lactuca sativa*, the common lettuce, and *L. virosa*, supply lactucarium, a substance used like opium. [J. H. B.]

**COMPOSITION.** The arrangement of organs, or their order of development, or their manner of branching, &c.

**COMPOUND, COMPOSITE.** When formed of several parts united in one common whole: as pinnated leaves, and all kinds of inflorescence beyond that of the solitary flower.

**COMPRESSED.** Flattened lengthwise; as the pod of a pea.

**COMPTONIA.** A deciduous bushy shrub

belonging to the order *Myricaceae*, bearing both male and female flowers in catkins, and on the same plant. A native of North America in moist peaty soils. The leaves are long and narrow, alternately arranged and cut on each side into rounded and numerous lobes, so as to resemble the fronds of *Ceterach* (hence the name *C. asplenifolia*), downy and sprinkled with golden resinous transparent dots, which, as well as the rest of the plant, have an aromatic scent. It was introduced in 1774 by the Duchess of Beaufort, and was named in honour of Henry Compton, Bishop of London, the introducer and cultivator of many curious exotic plants, and a great patron of botany and horticulture. It is hardy, but requires a peat soil and shade. In America it is called the Sweet Fern Bush; in France *Comptonia*, or *Liquidambar à feuilles de Ceterach*; but it must not be confounded with *Liquidambar styraciflua*, Sweet Gum. [C. A. J.]

**CONANTHERA.** A genus of *Liliaceae* containing a few small Chilean bulbous plants, with linear leaves, and a scape supporting paniculate blue flowers. Perianth six-parted, adhering to the base of the ovary, and breaking away by a transverse split as the fruit ripens; stamens six, united into a cone. [J. T. B.]

**CONCEPTACLE.** A term sometimes applied to the capsular fruit of red-spored *Algae*, in contradistinction to the fruit in which the reproductive mass is ultimately divided into four bodies, and hence called tetrasperma. Modifications have received the names of ceramidia, cystocarpa, faville, nuclei, &c. The explanation of these terms belongs rather to a treatise on *Algae* than to the present work. [M. J. B.]

Also, a special organ, developed in some fungi on the surface, or in the interior of a receptacle, and containing the organs of reproduction as well as their accessories; it differs from a spore-case in the latter being itself one of the accessories, and only containing spores.

**CONCHIDIUM.** *Eria*.

**CONCHIFORM.** Shaped like one valve of a common bivalve shell.

**CONCHOCYLUS.** *Appendicula*.

**CONCOLOR.** Of the same colour as some other thing compared with it.

**CONCOMBRE D'ÂNE, or SAUVAGE.** (Fr.) *Ecballium agreste*, the *Momordica Elaterium* of some.

**CONDAMINEA.** The name of a genus of *Cinchonaceae*, consisting of Peruvian shrubs, some of which have similar tonic properties to those contained in the true *Cinchona*, while others are used for dyeing purposes. The genus is known by the cup-shaped tube of the calyx, whose limb is five-toothed, and separates from the tube by a circular line. The corolla is tubular, concealing the stamens, which are attached near to the middle of its tube

The fruit is a top-shaped truncated capsule, opening by two valves, and containing several wingless seeds. [M. T. M.]

**CONDUPLICANT.** Doubling up; as when the leaflets of a compound leaf rise up and apply themselves to each other's faces.

**CONDUPLICATE, CONDUPLICATION.** A term of assivation; when the sides of an organ are applied to each other by their faces.

**CONDYLIUM.** The antherid of a *Chara*.

**CONE.** The strobilus or conical arrangement of scales in the fruit of a *Pinus* or fir-tree.

**CONE-FLOWER.** An American name for *Rudbeckia*. — **PURPLE.** An American name for *Echinacea*.

**CONE-HEAD.** A garden name for *Strobilanthes*.

**CONENCHYMA.** The conical cells which constitute hairs.

**CONFERRUMINATE.** Glued together.

**CONFERTUS.** When parts are pressed closely round about each other; packed close.

**CONFERVA.** The typical genus of *Conferraceæ*, the species of which are either attached to various bodies or float in dense masses or ponds swollen up with bubbles of gas, from whence the genus takes its name. The branched *Confervæ* are now separated under the name of *Cladophora*. *Confervæ*, when dried, were once used as a packing instead of tow, to support fractured limbs, a use which is now quite obsolete. The name was also applied to a vast heterogeneous mass of plants, as may be seen in *Dillen's History of British Confervæ*. [M. J. B.]

**CONFERVACEÆ.** A division of the green-spored *Algae* characterised by their simple or branched articulated threads, diffused endochrome, and small zoospores. The articulations are mostly as long as, or longer than, their diameter, which forms one of the main technical distinctions between them and the *Oscillatoria*, which have, however, a very distinct habit. The genera are numerous, and in some cases, as in *Chatophora*, the threads are compacted into a solid mass by means of gelatine. The zoospores sometimes occur in the ordinary cells of the threads, but sometimes in distinct cysts, and sometimes privileged cells are multiplied by cell-division for their production, as in *Stygoclonium*. They are found in all parts of the world, but are most plentiful in temperate regions. They are sometimes so abundant that, after floods, they form a thick coat, like paper, on the ground, to which the name of meteoric paper has been given. *Chroolepus* differs from the rest in its being developed in the air and not in water, and in its golden colour when fresh, but the species when dry become green. The fruit, however, like that

of *Callithamnion*, externally contains zoospores. [M. J. B.]

**CONFLUENT.** The fastening together of homogeneous parts. Gradually uniting organically.

**CONFORM.** Of the same form as some other thing.

**CONGELATIO.** In countries where frost is severe, most forest trees exhibit marks of serious injury, either in formidable fissures caused by differences of temperature in the different parts of the trunk, or in the death of portions of the bark and wood. Trees thus become accurate registers of severe winters. While, however, some plants give way at once under a slight degree of frost, others may be turned into a solid mass of ice without losing their vital powers, especially if the mass is thawed gradually, and in the dark. The outward parts of plants sometimes escape, when more delicate and protected parts are destroyed. Pear blossoms, for instance, may be apparently unharmed by frost and expand as usual, when the pistils are completely destroyed. The effect of frost on plants depends greatly upon the condition of soil. The wetter the soil, and the more saturated the plants with moisture, the more destructive is it. A degree of cold, which is quite harmless when the cells are comparatively empty, is positively destructive under other circumstances. [M. J. B.]

**CONGESTED.** Crowded very closely.

**CONGLOBATE.** Collected into a ball, as the florets of *Echinops*.

**CONGLOMERATE.** The same as clustered.

**CONGLUTINATE.** Glued together, not organically united.

**CONIDIA.** Many *Fungi*, besides their true fruit, produce little reproductive cells in different parts, especially on the spawn or mycelium which are known by the name of conidia. The substance called ergot is a good example, the conidia appearing some months before the perfect fungus. When these conidia are contained in distinct cysts or perithecia, they are called stylospores. In some cases undoubtedly, as in *Erysiphe*, the conidia are reproductive, but in others it is possible that they may perform the functions of male organs. The subject of impregnation, in *Fungi*, is so imperfectly known that it is not possible to speak with certainty about it. [M. J. B.]

**CONIDIUM.** The gonidium of a lichen.

**CONIFERÆ.** (*Conacæ*, *Pinacæ*, *Conifers*, the *Pine* family.) A considerable and important family, constituting with the smaller groups of *Cycadææ* and *Gnetacææ* the sub-class gymnosperms of dicotyledons. It consists of trees or shrubs, mostly with resinous secretions. The leaves are stiff, sometimes linear or needle-like, sometimes short and scale-like, or more rarely broad, lobed, or divided. The flowers are unisexual, either in cylindrical

or short catkins with closely packed scales, or the females are solitary. There is no perianth. The stamens in the males are either inserted on the axis of the catkin under the scales, or the anther-cells are sessile on the inside of the scales themselves, which then form part of the stamens. The ovules and seeds are naked, that is, without ovary, style, or pericarp, although sometimes more or less enclosed in two bracts, or in a fleshy or hardened disk. The seeds are albuminous, with one or sometimes several embryos in the centre, each embryo having sometimes more than two cotyledons. There are probably nearly two hundred species known, dispersed over a great part of the globe, several of them forming large forests in temperate climates, or more rarely within the tropics; while some of them extend almost to the utmost limits of woody vegetation in high latitudes, or at great elevations. They are distributed into about twenty-five genera, forming three tribes or sub-orders: 1. *Abietina*, with the fruits collected in cones, and inverted ovules; of this the principal genera are *Pinus* (including *Abies*), *Araucaria*, *Cunninghamia*, *Sequoia*, &c. 2. *Cupressineæ*, with the fruits collected in cones, and erect ovules; including *Juniperus*, *Callitris*, *Thuja*, *Cupressus*, *Taxodium*, *Cryptomeria*, &c. 3. *Taxaceæ*, sometimes considered as a distinct family, with the fruits solitary or loosely spiked, including *Podocarpus*, *Dacrydium*, *Phyllocladus*, *Salisburia*, *Taxus*, &c.

The woody tissue of the trees of this family is seen to be marked with peculiar circular dots or punctations when examined under the microscope. The ovules at the base of each cone-scale are generally held to be naked, each ovule having a large opening at its apex, to which the pollen from the stamens is applied directly. But some say that the ovules are not naked, but are contained in a proper ovary which is closely applied to the seed; that the outer membranous scales are modified leaves; and that the hard scales are altered branches bearing the pistillate flowers.

Some botanists look upon Conifers as the highest type of true dicotyledons. They are most abundant in temperate regions, both in the northern and southern hemispheres. In Europe, Siberia, and China, and in the temperate parts of North America, we meet with species of pine, spruce, larch, cedar, and juniper. In the southern hemisphere they are replaced by *Araucaria*, *Eutassa*, *Dammara*, *Podocarpus*, and *Dacrydium*.

Conifers are of great importance to mankind. They supply valuable timber, and yield resin, oil, pitch, and turpentine. Some attain a great size. Thus *Wellingtonia gigantea* has been known to attain in Oregon, a height of 450 feet, with a circumference of 116 feet at the base. *Taxodium sempervirens* also attains an enormous size. The various species of *Pinus* have their leaves in clusters of two, three, four, five, or six, surrounded by a membranous sheath at

the base. *Pinus sylvestris* is the common Scotch fir, which abounds in cold climates, and which supplies timber, turpentine, and pitch, as well as a hemp-like fibre from its leaves, which is used for stuffing pillows and cushions under the name of pine wool. *Pinus Pinaster*, the Bordeaux pine, thrives well on the sea-shore. *Abies* includes different species of fir and spruce, in all of which the leaves come off from the stem and branches singly. *Abies cecelæa* is the Norway spruce; *A. balsamea* the balsam of Gilead fir; *A. canadensis* the hemlock spruce; and *A. pectinata* the silver fir. *Cedrus* comprises those cedars which have clustered persistent leaves. *Cedrus Libani* is the cedar of Lebanon, the Eres of the Bible; while *Cedrus Deodara*, a local variety, is the sacred cedar of India. *Larix* includes the species of larch, which have clustered deciduous leaves. *Larix europæa* is the common larch; *L. Griffithii* the Himalayan larch. The *Araucarias* have single-seeded scales, with adherent seeds and many-celled anthers; *Araucaria imbricata* is a Chilean species; *A. bidwellii* is from Moreton Bay; both have edible seeds. *Eutassa cecelæa* is the Norfolk Island pine, which yields valuable wood. *Cryptomeria japonica* is the Japan cedar. *Cupressus sempervirens* is the common cypress. The Junipers have a peculiar succulent fruit. *Juniperus Bermudiana* furnishes the cedar for pencils. The species of *Thuja* are known by the name of Arbor Vita. [J. H. B.]

**CONIMA.** The fragrant gum resin of the lincense tree, *Leuca heptaphylla*.

**CONIOCYSTS.** Closed spore-cases resembling tubercles, and containing a mass of spores.

**CONIOGRAMMA.** A name given by Fée to the species of *Gymnogramma* represented by *G. javanica*. [T. M.]

**CONIOMYCETES.** A family of *Fungi* distinguished by the predominance of the spores over the receptacle. The spores are simple or articulated, solitary or chained together, and sometimes fasciculate, naked or enclosed in a distinct cyst. The plants, however, in which this last structure obtains are probably, for the most part, mere conditions of *Sphæria* and other pyrenomycetous *Fungi*. The most important members of the family, are the numerous parasitic species which affect the living organs of plants, and cause great mischief, especially amongst our corn crops, by exhausting the energies of the mother plant, and preventing the full development of the seed. One or two of these, which grow on different species of Juniper, approach *Tremella* in outward appearance, as all do in some peculiarities of structure. In most of these the spores exhibit bright colours, while in other divisions they are as generally black. The dark soot-like patches which are so common on old rails and dead wood are formed mostly by these dingy *Coniomyces*, which notwithstanding their unpromising appearance, are often full of interest when closely examined. [M. J. B.]

**CONIOSELIUM.** A genus of four species belonging to the *Umbelliferae*, and found in mountain districts in Central Europe, Siberia and North-west America. *C. Fischeri*, the best known species, and one which has long been cultivated in botanic gardens, is a biennial herb one to three feet high, with much the appearance of the hemlock, and having its small white flowers disposed in many-rayed umbels, without common, but with partial involucre of five to seven narrow linear leaves, which are equal in length to the flower-stalks.

The principal distinguishing features of the genus are found in the fruit, which is elliptical, dorsally compressed and about one-third of an inch long; each of the carpels has five winged ribs, the marginal ones twice the breadth of the others; and in the lateral furrows, there are three oil tubes (vittæ), seen in the form of dots when the fruit is cut across, usually two in the dorsal furrows, and four to eight on the inner face. [A. A. B.]

**CONIOTHECÆ.** The cells of an anther.

**CONIUM.** A genus of *Umbelliferae*, containing the well-known Hemlock. The botanical name has been given under the notion that this is the plant mentioned by the Greeks, under the same name, and which was administered, as a judicial means of execution, to Socrates and Phocion. The distinguishing characters reside in the fruit, which is somewhat globular in shape, and each half is marked with five wavy ridges. There are no vittæ or channels for oil, and the albumen is deeply furrowed on its inner surface. Such are the botanical characteristics, but the poisonous nature of *C. maculatum*, the common Hemlock, and

nial plant, with a tap-shaped root, a smooth shining hollow stem, two to five feet in height, frequently marked with purple spots, though these vary very much in number and intensity of colour. The leaves are much divided, with numerous small egg-shaped or lance-shaped deeply cut segments; the upper leaves are smaller. When bruised they emit a peculiarly nauseous odour, not at all aromatic, as is usually the case in our native umbelliferous plants. The inflorescence is a compound umbel, with ten or more rays, surrounded by a general involucre of three to seven leaflets; the partial umbels or umbellules, have at their base a small involucre of three bracts, which are all turned to one side, and do not surround the umbel, as in the case of the general involucre. The flowers are white or greenish white, and the fruits have the important characteristics before mentioned. In attempting the discrimination of this plant, all the above points must be attended to, as there are many plants possessing some of the characteristics of the true Hemlock, and which are in consequence frequently mistaken for it.

The active principle of Hemlock is a peculiar oily-looking fluid, lighter than water, and called *coniæ*. It exists in all parts of the plant, but especially in the fruits. It acts first as an irritant poison, but speedily causes paralysis of all the muscles, convulsions and death. The plant is of course much less dangerous than its extract, but in poisonous doses it produces similar symptoms, and sometimes coma, and other effects like those produced by opium. Medicinally *Conium* has been used for promoting the absorption of tumors, and glandular swellings, and as an antispasmodic and anodyne. [M. T. M.]

*Conium maculatum.*

its frequent growth in hedges and by roadsides in this country, demand a more full description.

The Hemlock is an erect branching biennial

**CONJUGATÆ.** A tribe of green-spored *Algae* distinguished from *Conferveæ* by their endochrome being spiral, stellate, or otherwise disposed, and not equally diffused, or simply denser in the centre; and by the large zoospores formed by the union of the endochromes of two contiguous cells, or one divided into two for the purposes of fructification in the same or in two different plants. In a few, impregnation is effected, in the manner described under *Bulbochete*, by means of free antheridia, which ultimately fix themselves near the spore-bearing cell. In some instances the bodies perfected by impregnation undergo cell-division, and the component parts become so many zoospores. The species are either attached or float freely in the water. Almost all are fresh-water plants, and are found in various parts of the globe, but especially in temperate regions.

The term *Conjugatæ* does not strictly apply to all. In *Edogonium* there is no conjugation, but fructification takes place by the division of a cell, one of the two divisions only proving fertile. In this genus, as also in some others, the spores are often of a brilliant scarlet or vermillion. The same spore, however, may be, in different stages

of growth, either green or red, a phenomenon not very uncommon amongst the green-spored *Alga*. Conjugation takes place also in *Desmidiaceae* and *Diatomaceae*, and also amongst moulds, as in *Synsphytes*, so common on decaying toadstools. [M. J. B.]

**CONJUGATE.** Paired; when the petiole of a leaf bears one pair only of leaflets.

**CONJUGATO-PALMATE.** When a leaf divides into two arms, each of which is palmate.

**CONJUGATO-PINNATE.** When a leaf divides into two arms, each of which is pinnate.

**CONJUNCTORIUM.** The operculum of the spore-case of an urn-moss.

**CONJURER OF CHALGRAVE'S FERN.** A name assigned by Relhan in his Flora of Cambridgeshire to *Puccinia anomones*; but whether a popular name or not we are unable to say. It is derived from the external resemblance of its little heaps of protospores to the fructification of Ferns. *P. anomones* is 'filiis lobata, globulis pulverulentis undique aspersa' of Ray's Synopsis, where it is figured, and named after a specimen in Bobart's Herbarium marked by his own hand—'This capillary was gathered by the Conjuror of Chalgrave.' The elder Bobart, it may be observed, died in 1680, and his son, who succeeded him, in 1719. [M. J. B.]

**CONNARACEÆ (Connaradæ).** A family of calycifloral dicotyledons, closely allied on the one hand to *Xanthoxylæ*, and on the other to *Leguminosæ*, differing from the former chiefly in the more completely apocarpous ovary, and from the latter in the perfectly regular flowers, and in the seed in which the radicle is always at a distance from the hilum. They are trees or shrubs, sometimes climbing, with alternate usually pinnate leaves; the stipules either small and deciduous, or wanting; the flowers small, in terminal or axillary racemes or panicles. There are five sepals and petals, ten stamens, and one to five carpels, with two ovules in each, and distinct terminal styles. There are about forty species, natives of the tropics of the New and Old World, and distributed into six or seven genera, of which the principal are *Rourea*, *Connarus*, and *Cnestis*. The aril in some species of *Omphalobium* is entire. Zebra-wood is obtained from *Omphalobium Lambertii*. They belong to Lindley's Rutæ Alliance.

**CONNARUS.** A genus of shrubs or trees, forming the type of the order *Connaraceæ*. The leaves are compound, without stipules; the flowers regular, with ten stamens united by their filaments at the base, the five which are opposite to the petals shorter than the rest. Of the five ovaries, four are generally abortive, and reduced to the condition of styles, while the fifth contains two ascending ovules; the stigma is dilated. The fruit is a kind of pod, but it does not open, and contains only one seed, the other being suppressed. The trees are

natives of India, and tropical South America. [M. T. M.]

**CONNATE.** When the bases of two opposite leaves are united together. Also when any parts, originally distinct, become united in after-growth.

**CONNECTIVAL.** Of or belonging to the connective.

**CONNECTIVE.** The part which intervenes between the two lobes of an anther and holds them together; it is subject to great diversity of form. It appears to be analogous to the midrib of a leaf, and is only absent when an anther is strictly one-celled; that is to say, when the whole of the interior of the end of the stamen is converted into pollen.

**CONNEMON.** The fruit of *Ocumis Conomon*, cultivated everywhere in Japan.

**CONNIVENT.** Having a gradually inward direction, as many petals; converging.

**CONOCARP.** A fruit consisting of a collection of carpels arranged upon a conical centre, as the strawberry.

**CONOCARPUS.** A genus of *Combretaceæ*, consisting of trees and shrubs from tropical America (one species extending northwards as far as Florida) and Western Africa, with alternate leathery entire leaves, and densely aggregated stalked heads of flowers on globular or oblong receptacles. Calyx about the length of the ovary to which it adheres; petals none; stamens five to ten exerted; ovary compressed, two-ovuled. The fruit is leathery, scale-like, forming imbricated cone-like heads. The Indian species, which were formerly placed in this genus, are now separated under the name of *Anogeissus*, having the calyx tube prolonged upwards far above the ovary. They produce very valuable timber, nearly as durable as teak, if kept dry. [J. T. S.]

**CONOCLINIUM.** The name given to a genus of the composite family, composed of a number of tropical American weeds, rarely exceeding three feet in height. It is characterised by a setose pappus, conical naked receptacle, and bell-shaped involucre, made up of two or three series of linear scales. The species, of which about ten are enumerated, bear much resemblance to each other. *C. coelestinum* is a common plant in thickets and waste places in the Southern and Western United States. It is a smooth or slightly hairy herb with opposite stalked leaves, which are oval in form, with notched margins. The flower-heads, in terminal corymbs, are very numerous, and about the size of a pea; the florets, of a bright blue or purple colour, are all tubular, and have a fragrant odour. The genus differs from *Eupatorium* only in the conical receptacle. [A. A. B.]

**CONOIDAL.** Resembling a conical figure, but not truly one, as the calyx of *Silene conoidea*.

**CONOMORPHA.** A genus of small ever-

green trees of the *Myrsine* family, found in the tropical parts of South America. The species have alternate stalked entire leaves of a leathery texture and full of dots, oblong or elliptical in form, and varying from three to seven inches in length. The small white or green flowers are borne on short stiff racemes, and have a calyx of four divisions; a funnel-shaped corolla with a four-parted border, enclosing four stamens; and a one-celled ovary, which is crowned with a short style. The fruit is a berry about the size of a pea, and contains few seeds. [A. A. B.]

**CONOPHOLIS.** A genus of *Orobanchaceæ*, containing a single species, a native of South America. It is a singular plant growing in clusters among fallen leaves, in oak woods. The stem is crowded with scales, which are at first fleshy, then dry and hard. The upper scales form bracts to the flowers, the lower are closely and regularly imbricated. The flowers are in a thick scaly spike, and have an unequally four to five cleft calyx, a bilobate slightly curved corolla swollen at the base, protruded stamens, and a depressed stigma. The fruit is an ovoid pod, with four placentæ approximated in the middle of each valve. The genus is nearly related to *Orobanchæ*, differing chiefly in having a bibracteolate calyx, and exserted stamens. [W. C.]

**CONOPSIDIUM.** *Platanthera*.

**CONOSPERMUM.** A genus of *Proteaceæ*, containing about forty species. It is distinguished by having a tubular four-cleft calyx, one of the segments of which is occasionally much larger than the others. There are four stamens on short filaments (one of which is sterile), inserted at the base of the calyx segments: the three anthers cohere together; style filiform, with a free oblique stigma. The fruit is a nut, containing a single silky seed. The inflorescence is either in spikes or panicles. The habit of the different species varies considerably; some are tall erect shrubs, while others are of much humbler growth. The foliage is very variable: in *C. imbricatum* the leaves are oval, scarcely a quarter of an inch in length; in *C. filiforme* and *C. ericifolium* they are narrow and sharp-pointed; in *C. cæruleum* they are spatulate, on very long footstalks; in *C. longifolium* and *C. flexuosum* they are nearly a foot in length, and not more than a quarter of an inch in width; while in *C. teretifolium* and *C. tenuifolium* they are filiform and a foot in length. A few species, as *C. phedroides*, *C. polycephalum*, are nearly leafless. This genus is confined to the extra-tropical portions of Australia: one species (*C. taxifolium*) is likewise found in Tasmania. [R. H.]

**CONOSTEPHIUM.** A genus of *Epacridaceæ*, containing five S. W. Australian species, branched erect shrubs, with scattered leaves, and solitary recurved axillary flowers. The calyx is five-parted, and is surrounded with four or more bracts; the corolla is five-toothed; the oblong anthers

are included; the ovary is five-celled, with a single pendulous ovule in each cell. The hard indehiscent drupe is one-celled from the abortion of the other cells. [W. C.]

**CONOSTYLIS.** A genus of New Holland *Hæmodoraceæ*, consisting of perennial herbs with distichous ensiform radical leaves, partially sheathing and equitant at the base, and corymbose or subsapicate heads of flowers at the top of a simple scape. The perianth is lanately woolly outside, its tube connate with the ovary, and the limb regular, persistent, and half expanded in a bell-shaped form; it has six stamens with short erect filaments, and a conically dilated hollow persistent tripartite style. There are about half-a-dozen described species. [T. M.]

**CONOTHAMNUS.** Two Myrtaceous shrubs, natives of Western Australia, having linear lance-shaped leaves, and flowers in heads, surrounded by ovate hairy bracts. The calyx is hairy and four-toothed at the margin: the stamens are numerous, united into five parcels, opposite to the petals; ovary three-celled; fruit a capsule included within the tube of the calyx united at the base with the branch, and containing one seed in each of its three compartments. [M. T. M.]

**CONRADIA.** A genus of *Gesneraceæ*, containing several species of shrubs or herbaceous plants, natives of the West Indies, and reaching into the southern districts of North America. They are shrubs, or rarely herbs, with petiolate generally dentate leaves, and axillary peduncles with a single flower or sometimes with many-flowered cymes. The calyx tube is adherent to the ovary, the limb five-cleft, or more or less deeply five-parted; the corolla is tubular or campanulate, and its limb nearly equally five-cleft. There are four didynamous stamens, with the rudiment of a fifth, but neither hypogynous disc nor gland. The capsule is two-valved, and has two-vascular placentæ with numerous minute seeds. This genus can readily be separated from its allies, by the absence of disc or glands around the ovary. [W. C.]

**CONSOLEA.** A name proposed for a genus of *Cactaceæ* in honour of M. Michel-Angelo Console, assistant-director of the Botanic Garden at Palermo, by whom the peculiar feature which serves to distinguish it from *Opuntia* was first observed in 1830. This essentially consists in the

species, which include both unarmed and prickly plants, are shrubby, with tall simple continuous and inarticulated stems, bearing a few lateral-apical branches, which fall off as the stem increases in height. The flowers resemble those of *Opuntia*, and are produced near the apices of the branches; they are succeeded by oblong compressed berries. *C. rubescens* is an example of the unarmed species; and *C. ferax* and *spinossima* of the aculeate series. [T. M.]

**CONSOLIDA.** A section of the ranunculaceous genus *Delphinium*, containing annual species with only one carpel. *D. orientale* and *D. Ajacis*, the rocket larkspurs, are often cultivated; and the blue variety of the latter occurs in Cambridgeshire as a corn-field weed, though it is usually considered as *D. Consolida* by British authors. The true *D. Consolida* differs by having glabrous carpels, and a corymbose inflorescence, not racemose or paniculate, as in *D. Ajacis*. It has been found in Jersey, but perhaps not truly wild. [J. T. S.]

**CONSOUDE GRANDE.** (Fr.) *Symphytum officinale*. — **HE'RISSE'E.** *Symphytum echinatum*. — **MOYENNE.** *Ajuga reptans*.

**CONTINUOUS.** The reverse of articulated. A stem is said to be continuous which has no joints.

**CONTORTED.** An arrangement of petals or corolline lobes, when each piece, being oblique in figure, and overlapping its neighbour by one margin, has its other margin in like manner overlapped by that which stands next it, as in oleander.

**CONTORTULICATUS.** Twisted back upon itself.

**CONTRAYERVA.** *Dorstenia Contrayerva*.

**CONULEUM.** The name given to a West African bush of the eleanthus family, with opposite entire leaves, which are oboval in form and pointed, while both surfaces are covered with scurfy scales. The small flowers are not known. The females, arranged in forked racemes, have a calyx with a cylindrical tube and a conical limb, and are provided with a little opening at the top through which the style protrudes. The fruit is not known. [A. A. B.]

**CONVALLARIA.** The Lily of the Valley is a plant so well known, and one which is so universally a favourite, that little need be said by way of description. A slender irregular stalk, a few inches high and slightly curved, bears from eight to twelve small bell-shaped milk-white flowers, arranged one above another, each on a stalk of its own, all bending towards the ground, symmetrically elegant in form, and of a delicate perfume. This stalk rises from the base of a pair of broadly-lanceolate leaves, tapering towards each extremity of a somewhat glaucous hue, clasped together at the base by sheathing scales, and scarcely unfolded by the time the flowers are in perfection. Without poetical or fanciful conventionalities, the Lily of the Valley is as perfect an emblem of purity, modesty, and humility, as the floral world can afford. It may seem idle to observe that a flower of this description cannot be that referred to in the Sermon on the Mount; but as that opinion is frequently broached in popular works, it may simply be observed, that it never grows in the open fields, and that there is nothing in its array to which the term 'glory' is applicable. Not a little unprofitable commentary might have been spared if the same

general meaning had been attached to the term 'Lilies of the Field,' which has by common consent been ascribed to the parallel phrase, 'Fowls of the Air,' while the passage itself would have gained in force and dignity by being kept clear from botanical disquisitions. The Lily of the Valley is an inhabitant of the woods in many parts of England, and has long been admitted into every garden. A variety with double flowers, and another of a reddish hue, are also cultivated; but these are far inferior to the wild form of the plant. Notwithstanding the fragrance of the flowers, they have a narcotic odour when dried, and if reduced to powder excite sneezing. An extract prepared from the flowers or roots partakes of the properties of aloes. A beautiful and durable green colour may be prepared from the leaves with lime. The genus belongs to the *Liliaceæ*. *C. majalis* is the only species retained, some others which were formerly included being now referred to *Polygonatum* and *Silene*. French, *Muguet de Mai*, *Lis de Mai*, or *des Vallées*. German, *Mayblume*. [C. A. J.]

**CONVERGENTI-NERVOSE.** When simple veins diverge from the midrib of a leaf, and converge towards the margin.

**CONVERGINERVED.** When the ribs of a leaf describe a curve and meet at the point, as in *Plantago lanceolata*.

**CONVOLUTE, CONVOLUTIVE.** When one part is wholly rolled up in another, as in the petals of the wallflower.

**CONVOLVULACEÆ.** (*Bindweeds*.) A natural order of corollifloral dicotyledons, included in Lindley's scabular alliance. Herbs or shrubs, usually twining, and with a milky juice, having alternate leaves without stipules, and regular flowers; the flower-stalks (peduncles) bear one or many flowers. Calyx five-divided, imbricated, persistent; corolla plaited; stamens five, alternate with the corolline lobes; ovary free, two to four-celled; ovules one to two in each cell; styles united, often divided at the top. Fruit a two to four-celled capsule, rarely one-celled, valves breaking off and leaving the dissepiments and placentas in the middle of the fruit; seeds large with mucilaginous albumen; embryo curved. Abundant in tropical countries, and rare in cold climates; they twine around other plants and creep among weeds on the sea-shore. The plants are characterised chiefly by their purgative qualities, and many of them are used medicinally. Jalap is procured from the root, or rather underground stem of *Exogonium* (*Ipomœa*) *Purga*, while the gum-resin called scammony is produced by *Convolvulus Scammonia*. *Ipomœa Bona nox* is the moonflower of Ceylon and other warm countries. *Batatas edulis*, sweet potato or Batatas, is cultivated in Carolina, Japan, and China, and succeeds within an annual isotherm of 59°. It is cultivated also in Spain and Portugal. In

the Philippine Islands the batatas or camotes are used for making soup, as well as roasted. There are forty-six known genera, and nearly 700 species. Illustrative genera: *Calystegia*, *Convolvulus*, *Exogonium*, *Ipomoea*, *Batatas*, *Pharbitis*. [J. H. B.]

**CONVOLVULUS.** An extensive and widely-distributed genus, typical of the order of bindweeds, consisting of twining or trailing annual and perennial plants, mostly with showy flowers expanding during the early part of the day. Among the allied genera of the order it is distinguished by its naked bractless calyx, funnel-shaped corolla, two linear often revolute stigmas, and two-celled capsule, each cell containing two seeds. The species share largely in the medicinal properties found in some other genera of the family; qualities which depend on the presence of a peculiar resin with purgative properties. *C. Scammonia* furnishes the scammony of the druggist; and in most of the perennial species, including the indigenous *C. arvensis* and *C. Soldanella*, the same principle occurs. *C. dissectus* abounds in hydrocyanic acid, and is said to be one of the plants from which the liqueur noyau is prepared. Some of the species are popular ornaments of the flower-garden, and with one at least everybody is familiar; viz. *C. tricolor* or Minor *Convolvulus* of the seedsman, a dwarf Mediterranean species with large flowers of a beautiful violet blue, the centre white and yellow. Of the perennial climbing species, *C. atropurpureus* with silky deeply-cleft ovate foliage and rose-coloured flowers is an example. *C. bryoniaefolius*, *C. italicus*, and *C. Subhorptii* are closely related to it, and not easily distinguished. *C. lineatus* with very narrow entire foliage, and flesh-coloured flowers, is occasionally met with in gardens; it is dwarfer and less showy than the preceding. A very distinct species is the *C. Onoserum*, indigenous to the south of Europe, of shrubby habit with persistent lanceolate foliage clothed with silvery hairs, and whitish flowers produced in terminal bunches in spring. *C. mauritanicus* is a pretty dwarf trailing species with oval wavy foliage, and numerous axillary flowers of a pleasing violet colour. [W. T.]

**CONYZA.** A genus of herbaceous or shrubby plants belonging to the radiate group of compound flowers, among which it is discriminated by its naked receptacle, its three-cleft outer-florets, and the rough pappus which crowns its fruit. The species possess no properties to render them attractive. They were formerly supposed to have the power, when suspended in a room, of driving away fleas; hence the English name Flea-bane, given also to an allied genus. *C. camphorata* and *marilandica* give out a strong smell of camphor. *C. carolinensis* is an evergreen shrub, a native of Carolina, growing to the height of five feet, and producing purple flowers from July to October. *Baccharis halimifolia*, a shrubby species with insignificant

white flowers is by some authors placed in this genus. French, *Herbe aux Puces*; German, *Dürrwurz*. [C. A. J.]

**COOKIA.** A genus of *Aurantiaceæ*, named in honour of the famous circumnavigator. It consists of small trees with compound leaves; whose leaflets are unequal at the base. The flowers have four to five concave petals; eight to ten stamens, distinct one from the other; the ovary on a very short stalk, four to five-celled, with two ovules in each compartment; and the style short and surmounted by a four to five-toothed stigma. The fruit is a globular berry, with five, or by suppression, fewer compartments, filled with juice. The fruit of one species, *C. punctata*, is esteemed in China and the Indian Archipelago, where it is known under the name of Wampee. [M. T. M.]

**COONDA OIL.** The oil of *Carapa guianensis*.

**COOPERIA.** A genus of *Amaryllidaceæ*, allied to *Zephyranthes*. They are bulbous plants with linear tortuous leaves, and one-flowered scapes. The perianth consists of a long erect slender cylindrical tube widened at the mouth, and a stellate limb of six regular equal segments; the filaments are nearly equal, erect, inserted in the mouth of the tube; the style erect with a three-lobed fimbriated stigma. The species, of which but few are known, are natives of Texas. The typical one, *C. Drummondiana*, has narrow tortuous leaves, twelve to eighteen inches long; and a scape of six inches to a foot high, bearing at the end a single flower, of which the tube is four and a-half inches long, greenish, often fading red, and the limb, rather over an inch long, and white. The flower always expands in the evening, and is not usually perfect after the first night, the limb becoming less stellate, and its margins curled, but it lasts three or four days in that state. 'The nocturnal flowering of this plant is an anomaly in the order, and the more remarkable because its nearest kin, *Zephyranthes*, requires a powerful sun to make it expand. The flower is fragrant, smelling like a primrose.'—Herbert. *C. pedunculata*, called also *Sceptranthus*, is also a nocturnal blooming fragrant plant. [T. M.]

**COOPER'S WOOD.** *Alphitonia excelsa*.

**COPAIVA TREE.** *Copaifera officinalis*, which, with other species of *Copaifera*, yields Copalvi balsam.

**COPAI YÉ.** The wood of *Fochys guianensis*.

**COPAL.** A name applied to a gum resinous product of various tropical trees. —, BRAZILIAN, obtained from several species of *Hymenaea*, and from *Trachylobium Martianum*. —, INDIAN, produced by *Vateria indica*. —, MADAGASCAR, produced by *Hymenaea verrucosa*. —, MEXICAN, supposed to be the produce of some *Hymenaea*. —, SANSIBAR. The product of *Trachylobium Martianum*.

**COPALCHE PLANT.** *Strychnos pseudoquina*, which furnishes the Brazilian copalche bark; also *Ocotea pseudo-china*, the bark of which is called copalche bark in Mexico.

**COPALM BALSAM, or COPALME D'AMÉRIQUE.** (Fr.) A liquid balsam obtained from *Liquidambar styraciflua*.

**COPERNICIA.** A genus of palms named in honour of the celebrated Copernicus. It comprises six species, inhabiting tropical America, but three of them are almost unknown. They grow twenty, thirty, rarely forty feet high, their trunks being covered by the remains of leaf-stalks, and surmounted by tufts of fan-shaped leaves, from amongst which the branching spikes of small greenish flowers are produced, each spike having several sheathing bracts scattered along its stalk. The flowers are either perfect or imperfect, and have a cup-shaped calyx with three small teeth, a bell-shaped corolla with the upper part cut into three divisions, six stamens fixed to the inside of the corolla, and three ovaries more or less cohering together. The fruit is yellowish, of an elliptical form, and contains a single seed.

The Carnaúba or Wax-Palm of Brazil, *C. cerifera*, grows about forty feet high, and has a trunk six or eight inches thick, composed of very hard wood, which is commonly employed in Brazil for building and other purposes, and is sometimes sent to this country and used for veneering. The upper part of the young stems, however, is soft, and yields a kind of sago; and the bitter fruits are eaten by the Indians. The young leaves are coated with wax, called carnaúba wax, which is detached by shaking them, and then melted and run into cakes; it is harder than bees' wax, and has been used by Price and Co. for making candles, but as no process of bleaching has been discovered, they retain the lemon-coloured tint of the raw wax. The leaves are also used for thatching, making hats, &c., and while young as fodder for horses. [A. S.]

**COPPERY.** Brownish red, with a metallic lustre.

**COPRINUS.** A genus of gill-bearing fungi remarkable for their dark spores and deliquescent pileus. The gills moreover adhere together in consequence of the great projection of the transparent processes supposed to be antheridia. The species are numerous, of extremely rapid growth, and are developed for the most part on dung hotbeds or very rich manured soil. They have even been found on the dressings of fractured limbs. A few hours is often sufficient for their complete development and decay. *C. atramentarius* yields a very dark juice which has sometimes been used for ink, and both that and some other species are mixed with other fungi to make ketchup. *C. comatus* is sometimes eaten when young and is said to be both delicate and wholesome. *C. bolbitis* is distinguished by its salmon-coloured spores. [M. J. B.]

*is* is distinguished by its salmon-coloured spores. [M. J. B.]

**COPROSMA.** A genus of cinchonaceous shrubs, owing their name to their fetid smell. The flowers are polygamous, each whorl of from four to nine divisions; the stamens project from the somewhat bell-shaped corolla; the ovary has two to three compartments, and is surmounted by an epigynous disc. The fruit is a berry with two or three seeds. The leaves of *C. fastidiatum* are used by the New Zealand priests to discover the will of the gods. The leaves are attached with a cord of flax to sticks, which are laid on the ground, each stick representing a separate party. The priests retire to pray, and after a time the chiefs are summoned to examine the sticks, which are found to have been moved, and some have disappeared entirely; this is considered a certain sign that one of the party will be destroyed. Others are found turned over. If the leaf be turned down, the omen is bad, but if the reverse should occur, it is a sign that the party represented by the stick will prosper in their undertakings. See Bennett's *Gatherings of a Naturalist in Australia*. [M. T. M.]

**COPTIS, Gold Thread.** A genus of *Ranunculaceæ* containing a few North American and North-east Asian herbs (one of which extends into Russia) with creeping rootstocks and trifoliate or biternate radical leaves and simple or branched scapes with small white flowers, with five or six petaloid deciduous sepals and as many petals; fifteen to twenty-five stamens, and five to ten foliaceous stalked carpels diverging in the form of a star, with four to eight seeds in each. The bitter rhizomes are used in America as a tonic, and also yield a yellow dye. [J. T. S.]

**COPTOPHYLLUM.** The name of a section or group of *Anemia* in which the caudex produces distinct sterile and fertile fronds. It contains one or two beautiful dwarf species, as *A. bursifolia* and *A. millefolia*. [T. M.]

**COQUARDEAU.** (Fr.) *Chetanthus fenestralis*.

**COQUE.** (Fr.) *Cocculus*.

**COQUELICOT.** (Fr.) *Papaver Rhæas*.

**COQUELOURDE.** (Fr.) *Anemone Pulsatilla*; also *Lychnis coronaria*.

**COQUELUCHIOLE.** (Fr.) *Cornucopia*.

**COQUERELLE.** (Fr.) *Anemone Pulsatilla*.

**COQUERET.** (Fr.) *Physalis Alkekengi*. —, **COMESTIBLE.** *Physalis peruviana*.

**COQUILLA NUTS.** The seeds of *Attalea funifera*.

**COQUITO.** The Chilian name of the palm *Jubæa spectabilis*.

**CORACAN.** (Fr.) *Eleusine Coracana*.

**CORACINOUS.** Raven-black.

**CORAÇA DE JESU.** *Mikania officinalis*.

**CORAIL DES JARDINS.** (Fr.) *Capsicum annuum*.

**CORAL BERRY.** An American name for *Symphoricarpos vulgaris*.

**CORALLIFORM, CORALLOID.** Resembling coral in general appearance.

**CORALLINA, CORALLINEÆ.** A genus and division of rose-spored *Algae*, the latter characterised by their calcareous rigid fronds, which when fresh are purple, fading to creamy white. Some are shrubby and jointed, others are crustaceous, and often adhere closely to their matrix, as pebbles, shells, seaweed, &c., while others present clavate or nodular forms, and are at length free from any attachment. When treated with hydrochloric acid their structure becomes visible under the microscope, and in some, as in *Corallina*, tetraspores have been discovered. The whole group, however, requires further investigation, and when the fruit is discovered in all the genera, it is probable that they will be absorbed into other groups. From the great quantity of carbonate of lime which they contain, some of the species, but especially *Corallina officinalis*, which is very common on our coasts, have been employed in medicine. They have, however, no specific properties beyond common chalk, which is a much more convenient substance. Crabs' eyes, crabs' claws, and red coral may be considered as belonging to the same pharmaceutical category. [M. J. B.]

**CORALLINES.** See *Corallineæ*.

**CORALLORHIZA.** A genus of orchids consisting of a small number of brown or yellowish terrestrial parasitical herbs, natives of moist woods and shady places in Europe, North America, and Northern Asia. Their leaves are reduced to small scales of the colour of the stems; their flowers are small in a loose terminal spike, the sepals and petals nearly alike, the lip larger and often white, the column short, with a terminal bud-like anther, and two pairs of globular pollen masses attached laterally. *C. innata*, the only European species, occasionally occurs in some parts of Scotland. It is a slender plant of six to nine inches high, of a pale colour, and remarkable for its rootstock, formed of a number of short thick whitish fleshy fibres, repeatedly divided into short blunt branches, and densely interwoven, which, from their resemblance to coral, have given the name to the genus.

Two species are found in Mexico, of which one, *C. bulbosa*, has its stem distended into a kind of corn at the base. The largest flowered species inhabits North-west America. *C. indica* was found by Dr. T. Thomson in the North-western Himalaya. A supposed species called *C. foliosa*, because it bears a true leaf, now forms part of the genus *Oreorchis*.

**CORAL-ROOT.** The common name for

*Corallorhiza*; also sometimes applied to *Dentaria bulbifera*.

**CORAL-TREE.** The common name for *Erythrina*.

**CORALWORT.** *Dentaria bulbifera*.

**CORBEILLE D'ARGENT.** (Fr.) *Iberis sempervirens*. — **D'OR.** (Fr.) *Alyssum saxatile*.

**CORBULARIA.** A genus of amaryllids, commonly called Hoop-petticoats. It is a small group sub-divided from *Narcissus*, and its chief peculiarities are a funnel-shaped tube to the perianth, an inconspicuous limb with small narrow spreading segments, and a large funnel-shaped cup, which is longer than the tube itself; the filaments and style are declinate and recurved, the sepaline filament inserted at the base, and the petaline near the base of the tube. The species are pretty dwarf hardy bulbs with very narrow half-terete leaves, and comparatively large showy flowers, one to three together on the scape. The species are found in the middle and south of Europe. *C. Bulbocodium*, the common Hoop-petticoat and the type of the genus, is a small plant, with conical bulbs as large as a nut, three or more leaves from four to eight inches long, and a one-flowered scape four to six inches long; the flower an inch long, pale yellow, with narrow linear lanceolate segments, the cup or coronee prominent truncate deep yellow. The few species vary chiefly in size and colour. [T. M.]

**CORCHORUS.** This genus of *Tiliaceæ* contains between forty and fifty species of herbaceous plants or small shrubs, with simple leaves, inhabitants of both hemispheres, but seldom found far beyond the tropics. Their flowers are produced either singly or in clusters opposite the leaves. They have a calyx of five deciduous sepals, and a corolla of five petals, with numerous stamens, a very short tubular style, and from two to five stigmas. Their fruit is long and pod-like or roundish, and splits when ripe into five divisions, each of which has numerous seeds arranged in rows on either side of a longitudinal partition.

*C. capularis* is an annual Asiatic plant, growing about ten or twelve feet high, and having a straight cylindrical stem as thick as the little finger, and seldom branching till near the top. Its leaves are about six inches long by one and a half or two broad towards the base, but tapering upwards into a long sharp point, and having their edges cut into saw-like teeth, the two teeth next the stalk being prolonged into bristle-like points. The flowers are yellow, and produced in clusters of two or three together: they are succeeded by a small almost globular but flat-topped fruit. This species, as well as *C. olitorius*, yields the exceedingly valuable fibre known under the name of Jute. Only twenty years ago, Jute was hardly heard of out of India, where it had long been in use amongst the natives for making cordage and cloth, but it now forms a very important article of

commerce; no less than 738,063 cwt., valued at \$19,6681., having been imported to this country alone in 1858. The plant is largely cultivated in India; also by the Malays and Chinese. The fibre is separated by the ordinary process of steeping in water. It is frequently as much as twelve feet in length, very soft, silky, and separable into fine filaments, which are easily spun. Jute is much used in the manufacture of carpets, and some kinds of cloth; but is not suitable for cordage, as it will not bear exposure to wet. Its most important use, however, is for the manufacture of the gunny-bags, so extensively used for packing cotton, rice, and other dry goods, enormous quantities of them being exported from India to the United States for that purpose. Very good paper is made from the refuse fibre, and also from worn-out gunny-bags; and a kind of whisky, resembling corn-spirit, has been distilled from the waste ends of the stems.

*C. olitorius*, is a native of India, but is now naturalised in all parts of the tropics, and extends as far north as the shores of the Mediterranean. It is an annual plant much resembling *C. capsularis*, the principal difference existing in the fruit, which in this species is two inches long, almost cylindrical, and about the thickness of a quill. The young shoots of this species are commonly used as a pot-herb in tropical countries, as are those of *C. capsularis*; It is much grown for this purpose in Egypt and Syria, and being used by the Jews, it has obtained the name of Jews' Mallow. It yields part of the Jute of commerce.

*siliquosus*, a common species in the West Indies and tropical America, is an herbaceous plant about two or three feet high; its leaves differ from those of the two last in not having bristles on the two bottom teeth, and there is usually a line of minute hairs along the stem. The negroes in the West Indies use it for making be-soms, and the inhabitants of Panama drink an infusion of the leaves as a substitute for tea; hence they call it *te*. [A.S.]

**CORCULUM.** The embryo; and also, the small axis of growth in such dicotyledonous embryos as the walnut.

**CORDATE.** A plane body, having two round lobes at the base; the whole resembling the heart in a pack of cards.

**CORDATO-HASTATE.** Between cordate and hastate.

**CORDATO-OVATE.** Between cordate and ovate.

**CORDATO-SAGITTATE.** Between cordate and sagittate.

**CORDELYSTYLIS.** A little known genus of Indian orchids described by Falconer in the *Journal of Botany* (iv. 75). It seems to be related to *Spiranthes*.

**CORDIA** (including *Myxa*, *Pilicordia*, *Rhynodocalyx*, and *Sebestena*). A genus of *Boraginaceae*, containing nearly 200 species of plants scattered over the tropical and sub-

tropical regions of the world. They are trees or shrubs with alternate rarely sub-opposite petiolate and entire or subdentate leaves, and flowers variously arranged, sometimes polygamous, or monocious from the abortion of parts. The calyx is tubular with four or five teeth; the corolla is funnel-shaped with the limb four to five-parted, rarely six to twelve-lobed; the stamens are as numerous as the divisions of the corolla, and are inserted in the tube; the ovary is four-celled, and bears a doubly-blind style, with a stigmatic surface on each division. The drupaceous fruit is ovate or globose, pulpy, generally surrounded by the persistent calyx, and four-celled or one to three-celled from the abortion of one or more cells; there is a single seed in each cell. This large unwieldy genus has been divided into the following sections from characters obtained from the calyx; and it would be well if these sections were raised into genera:

*Gerascanthus*, having a cylindrical ten-grooved calyx.

*Pilicordia*, with an oblong or cylindrical ten-striate calyx.

*Physoclada*, having a membranaceous calyx, hispid at the apex with setae, and at length irregularly torn.

*Sebestenoides*, having a cylindrical or ovate smooth three to ten-toothed calyx.

*Myxa*, the calyx not grooved, four to five-toothed, the teeth short or rarely awn-shaped.

*Cordiopsis*, with an obovate or oblong calyx terminating in five setaceous divisions.

The fruit of some species is eaten, as of *C. latifolia* and *C. Myxa*, two Indian species which have succulent mucilaginous and emollient fruits. From their mucilaginous qualities, combined with some astringency, they have been employed as pectoral medicines, under the name of *Sebestena*. The fruit of *C. abyssinica* is used in the same way in Abyssinia. The bark of *C. Myxa* is a mild tonic, and is used in India for astringent gargles. Some species supply useful and ornamental timber; the wood of *C. Rumphi* is brown, beautifully veined with black, and smells of musk. *C. Gerascanthus* yields a timber of importance in the West Indies. The wood of *C. Myxa* is soft, and of little use except for fuel. It is reckoned one of the best kinds for kindling fire by friction, and it is said to be the wood which was used by the Egyptians in constructing their mummy-cases. See Plate 6, c, and Plate 10, e. [W.C.]

**CORDIACEÆ.** A tribe or suborder of *Boraginaceae*, often considered as forming a distinct family. They differ from true *Boraginaceae*, but agree with *Ehretiaceae* in their concrete entire ovary internally divided into four or more cells; and are distinguished from both of those suborders by their branching style, and most frequently by their plaited cotyledons. They are trees, shrubs, or rarely herbs, with alternate rough leaves; their flowers are in terminal cymes, sometimes gyrate as in true *Bora-*

*ginea*, or rarely solitary. The fruit is usually more or less drupaceous. There are above 180 species, natives of the tropical or subtropical regions both of the New and the Old World, and have been distributed into about twelve genera, most of which have, however, been since reduced to *Cordia* itself.

**CORDICEPS.** A fine genus of Sphaeriaceous *Fungi* distinguished by its fleshy texture, vertical stipitate stroma and filiform articulate spores, which separate at the articulations. The species are the most remarkable amongst the very important group to which they belong. A few grow upon dead leaves, decaying branches, or ergoted grains, the rest upon pupae or larvae of insects. The New Zealand *C. Robertii* occurs on the caterpillar of a species of *Heptalus*, and is frequently brought home as an object of curiosity. We have two or three fine species in this country, of which *C. militaris* is remarkable for its brilliant scarlet hue. *C. alutacea*, which is of a pale tan, grows upon pine leaves, and a form of it, or distinct species, on *Ulex europaeus*. There is no doubt that, in many cases, the fungus-bearing insects are attacked during their lifetime; and there is one species of *Cordiceps* which occurs on wasps in the West Indies, which is considerably developed before the insect dies. The wasps so attacked are known by the name of *Gûépés végétantes*. The peculiarities of the species which grow on ergot will be noticed under that head. *C. sinensis* is supposed by the Chinese to have healing properties, and is sold as a drug in little bundles. [M. J. B.]

**CORDIFORM.** When a solid has the form of cordate.

**CORDLEAFS.** A name given by Lindley to the group of restiaceous plants.

**CORDON DE CARDINAL.** (Fr.) *Polygonum orientale*.

**CORDYLANTHUS.** A genus of *Homallices* from Java. It is allied to *Blackwellia*, but with an elongate club shaped perianth tube, adhering to the ovary, the limb ten or twelve-parted, and the segments in two rows, the inner longer and petaloid; leaves alternate, shortly-stalked, leathery, elliptical, toothed; flowers white, racemose, axillary; peduncles one to three-flowered; stamens fifteen or twelve; styles three to five; ovary one-celled. [J. T. S.]

**CORDYLINA.** A genus of erect-stemmed shrubby palm-like *Liliaceae*, bearing spreading and very ornamental heads of narrow elongate striated leaves, and terminal panicles of numerous small flowers. The perianth is deciduous, tubulose bell-shaped, with a six-cleft or six-parted spreading limb of linear segments, inserted in two rows; and there are six stamens with linear filaments inserted in the mouth of the tube. The ovary is three-celled with one ovule in each cell; and the style is filiform with a capitate three-lobed stigma. The fruit is a globose three-celled berry,

often by abortion one or two-seeded. The species are found in tropical Africa, in Madagascar, and the Mascarene Islands, and in the Malayan Archipelago. The typical species, *C. rotunda*, a native of the Mauritius, St. Helena, and Madagascar, has a naked simple stem, bearing a crowded head of numerous ensiform striated leaves, six or seven inches long, and scarcely half an inch wide. The flowers are fragrant, numerous, yellowish green, in a branched terminal raceme. *C. fragrans*, a West African species, has a tall stem with a terminal head of lanceolate leaves, two to three feet long, and two to three inches broad, and divaricately-branched panicles of fragrant white flowers, collected into dense umbellate heads. *C. Stebbellii* is a compact growing species with oblong leaves, four to six inches long, deep green, ornamentally blotched with paler green, and producing short terminal panicles of greenish-white flowers. Some very ornamental species formerly included in *Cordylina*, are now referred to the genera *Caladragon* and *Dracænopsis*; and others less striking in their appearance to *Chariswoodia*. [T. M.]

**CORDYLOBLASTE.** The name given to a Javanese tree, perhaps a species of *Camellia*. It has elliptic entire pointed leaves; flowers in whorls of five; stamens united into a tube, the upper edge of which has six anthers on it and ten or twelve teeth, while numerous other anthers are attached to the inner surface of the tube of the stamens; style simple; ovary seated on a fleshy disc, which is adherent to the base of the calyx, with one many-seeded compartment. [M. T. M.]

**CORDYLOGYNE.** A genus of *Asclepiadaceae*, consisting of a single herbaceous plant growing at a height of 4,000 feet on the mountains of Southern Africa. The plant has many erect slender stems about a foot high, long linear leaves, and pale green flowers clustered in many-flowered long peduncles. The calyx consists of five small hairy sepals; the corolla is five-parted, the divisions erect, and at length spreading; the staminal crown consists of five oblong leaves with angular processes on their lateral margins; the anthers are terminated by a triangular opaque apex, adpressed to the base of the oblong fleshy stigma; the pollen masses are attached by slender-kneed processes to a small simple corpuscle; the follicle is solitary, slender, and erect, with comose seed. [W. G.]

**COREMA,** Portugal Crakeberry. An erect much-branched low shrub of rigid habit, closely allied to *Empetrum*, from which it is distinguished by having no scales at the base of its calyx, and by its white three-seeded globose berries. The branches are slightly downy; the leaves obtuse, small, and narrow, with revolute edges, and sprinkled with resinous dots; flowers white, growing in terminal groups very like those of *Empetrum*, but larger. It is a native of Portugal and other coun-

tries of Southern Europe, and is described by some authors under the name of *Empe- trum iustianicum*. [C. A. J.]

**COREOPSIS.** A genus of American herbaceous composite plants remarkable for the singular shape of its seeds, which are flat on one side, convex on the other, membranous at the edge, and having the pappus furnished with two horns not unlike the antennae of an insect. Hence its name, which in Greek signifies 'bearing resemblance to a bug.' Many species are cultivated, among which *C. diversifolia* is a perennial with branching stems, small three to five-lobed leaves and large terminal flowers, the disk of which is purple, and the rays yellow, marked with a purple stain at the base. Several beautiful annual species, as *C. tinctoria*, *C. coronata*, *C. Atkinsoniana*, and *C. Drummondii*, are now referred to *Calliopsis*. *C. verticillata* is a handsome shrubby perennial; continuing long in flower; its flowers are used in North America to dye cloth red. [C. A. J.]

**CORESES.** Dark red, broad, discoid bodies, found beneath the epicarp of grapes.

**CORETTE POTAGE'RE.** (Fr.) *Corchorus olitorius*.

**CORETHROSTYLIS.** A group of W. Australian bushes belonging to the *Sterculiaceae*, remarkable for the form of the style, which is elongated and furnished with numerous tufts of recurved hairs, giving it the appearance of a bottle-brush. This curious appearance has suggested the name. About seven species are known, all of them having their parts more or less covered with rusty-coloured starry hairs. Their leaves are alternate, mostly heart-shaped, and either entire or notched. The flowers are in branched racemes, which arise from opposite the leaves, each flower supported by a bract, and consisting of a five-parted petal-like calyx covered with soft hairs; no petals; five stamens with short stalks, and anthers opening at the apex by a small pore, surrounding a three-lobed ovary, which, when ripe, becomes a three-celled capsule with three seeds. *C. bracteata* is a pretty bush sometimes seen in greenhouses: it has heart-shaped entire leaves about an inch in length, covered like all parts of the plant with rusty hairs. The plants are now referred to the genus *Lasiosyphum*. [A. A. B.]

**CORIAEOUS.** Having the consistence of leather.

**CORIANDER.** *Coriandrum sativum*.

**CORIANDRUM.** A genus of *Umbelliferae* producing the fruits erroneously called Coriander seeds. There is but one species, *C. sativum*, a native of Southern Europe, the Levant, &c., and cultivated even in this country, where it is also sometimes met with in a half wild condition. It has a branching annual stem, one to one and a half foot high, with the lower leaves

pinnately divided into broad or wedge-shaped deeply-cut segments, while the upper leaves are more finely cut. The umbels have five to eight rays without a general involucre, and the partial ones consist of only a few small bracts; the flowers are whitish or pink. The most characteristic feature, however, is the globular fruit, which is crowned by the teeth of the calyx, and has no oil channels on the outer surface, but two on the inner face of each half of the fruit; the ridges are five and rather indistinct. The two carpels of which the fruit is composed do not readily separate one from the other. Coriander fruits or seeds are carminative and aromatic, and are hence used for flavouring purposes in curries, &c., &c. The odour and taste depend upon a volatile oil. The fresh plant has a strong smell of buga. [M. T. M.]

**CORIARIA.** A genus of shrubs of uncertain position, by some made to constitute a distinct family under the name of *Coriariaceae*. The leaves are opposite, simple, ribbed, and entire. The flowers are in clusters, either hermaphrodite, monocious, or dioecious; calyx five-parted, bell-shaped; petals five, fleshy, with a prominent ridge internally; stamens ten, arising from beneath the ovary, which consists of five carpels arranged obliquely upon a thickened receptacle; stigmas five; ovules solitary, pendulous, inverted. Fruit of five crustaceous indehiscent one-seeded carpels, concealed by the membranous sepals and fleshy petals. These shrubs are natives of Southern Europe, the Mediterranean, Peru, Nepal, and New Zealand. *C. myrtifolia*, the European species, is a low deciduous shrub with myrtle-like leaves. Its fruit is poisonous, and is said to have proved fatal to some French soldiers in Catalonia. The leaves have also been used to adulterate senna—a dangerous fraud, as they are stated to have caused tetanic convulsions, and subsequent coma. *C. myrtifolia* is also used in dyeing black. *C. coccinea*, the Wineberry shrub of the settlers in New Zealand, has pendulous branches; greenish white flowers in long slender clusters, and shining-black berry-like fruits, full of a dark red juice of sweet taste, and free from any deleterious properties, but the seeds if eaten are poisonous; the natives therefore having expressed the juice from the fruits, strain it before they drink it, or soak their baked fern root in it. The 'missionaries at the Bay of Islands,' says Dr. Bennett, from whose *Wanderings in Australia* this notice is taken, 'make an agreeable wine from the berries of the shrub, which tastes like that made from elderberries.' The effects that result from eating the seeds are convulsions and delirium, which continue for several hours, and frequently terminate fatally. The fruit of *C. nepalensis* is also eaten in Northern India. [M. T. M.]

**CORINDE.** (Fr.) *Cardiospermum Halim-*

**CORINTHS.** The berries of the Corinthian grape, the Currants of the shops.

**CORIS.** A genus of *Primulaceæ*, containing a single species, a native of the western coasts of the Mediterranean. It is a lowly branching herbaceous plant, with alternate linear coriaceous leaves, and flowers in dense terminal spicate racemes. The calyx is campanulate with a

the upper two are the largest; the corona is tubular, with the limb bilabiate and cleft into five emarginate lobes, the two upper of which are the smallest; the stamens are scarcely exerted; the slender filaments have glands at their base on the corolla tube; the ovary is obovate, and has a subglobose placenta; the globose capsule has five valves and five seeds. [W. C.]

**CORISPERMUM.** A genus of *Chenopodiaceæ*, containing wiry-stemmed hairy annual herbs from Eastern Europe and temperate Asia. Leaves narrow, sessile; flowers very small, solitary in the axilla of the leaves, forming spikes; perianth of a variable number of small scales, rarely of one, or absent; stamens one to five, but generally three; the lateral ones often sterile; ovary compressed with short style and two stigmas; fruit compressed often margined. Abundant in the marshy steppes of Southern Russia. [J. T. S.]

**CORK, KÖRKER.** The name in the Scotch Highlands of *Leacanora tartarea*, where, Dr. Lindsay informs us, it is made into a domestic dye by macerating the powdered lichen for some weeks in putrid urine, with the addition of kelp or salt, and when the requisite crimson or purple tint is obtained, forming the paste into balls or lumps with lime or burnt shells, and hanging it in bags to dry. When used it is powdered, and then boiled in water with a little alum. In the island of Shetland both the dye and the lichen are called Korkalctt. [M. J. B.]

**CORK-TREE.** *Quercus suber*, the bark of which is cork. —, INDIAN. *Millingtonia portensis*.

**CORK-WOOD.** *Anona palustris*. — NEW SOUTH WALES. *Duboisia myoporoides*. — WEST INDIAN. *Ochroma Lagopus*.

**CORM.** A fleshy underground stem, having the appearance of a bulb, from which it is distinguished by not being scaly.

**CORMAU or CORNIAU.** (Fr.) A kind of olive.

**CORMIER.** (Fr.) *Sorbus domestica*.

**CORMOPHYLLUM.** A name given by Newman to a genus of Ferns having an erect caudex 'eventuating in fronds,' and in which he proposed to unite the species usually referred to *Cyathea*, *Hemitelia*, and *Allophila*. [T. M.]

**CORN.** A general term applied to the

cereal or grain-producing grasses. — **BROOM.** *Sorghum Dora*, the panicles of which are made into brooms, and the grain used for poultry food. — **KAFFIR.** A species of *Sorghum*, probably *S. saccharatum*. — **GOOSE.** *Juncus squarrosus*. — **GUINEA.** *Sorghum vulgare*; also applied in the West Indies to several grain-bearing species of *Panicum*, as *P. pyramidale*, *scabrum*, &c. — **INDIAN.** The maize, *Zea Mays*.

**CORNACEÆ.** An inconsiderable natural order of polypetalous calycifloral dicotyledons, belonging to Lindley's umbellal alliance. Trees or shrubs usually with opposite leaves having no stipules; flowers in cymose clusters or in heads surrounded by an involucre; calyx adherent, its limb four-toothed; petals four, valvate in bud; stamens four, alternate with the petals; styles united into one; ovary two-celled; ovules solitary, pendulous. Fruit a two-celled drupe (like a cherry). Natives of the temperate parts of Europe, Asia, and America. The plants of this order are used as tonics and in ague. *Cornus mascula* is the akenia of the Greeks, and the kiziljiek or red-wood of the Turks. From the wood of this plant the Turks obtain the dye for their red fez. The fruit stewed and mixed with water forms a good drink in hot weather, and from its astringency it is useful in bowel-complaints. Various species of *Cornus* or dogwood are used in America as substitutes for Peruvian bark. There are nine known genera and forty species. Illustrative genera:—*Cornus*, *Benthania*, *Aucuba*. [J. H. B.]

**CORNARET.** (Fr.) *Martynia*.

**CORN CAMPION, CORN CCKLE.** *Agrostemma Githago*.

**CORNE-DE-OERF.** (Fr.) *Coronopus vulgaris*.

**CORNEILLE.** (Fr.) *Lysimachia vulgaris*.

**CORNEL.** (CORNOUILLE, Fr.) The Cornelian cherry, *Cornus mascula*. — **WILD** or **FEMALE.** The dogwood, *Cornus sanguinea*.

**CORNEOUS.** Horny; hard and very close in texture, but capable of being cut without difficulty, the parts cut off not being brittle: as the albumen of many plants.

**CORN-FLAG.** The common name for *Gladiolus*.

**CORN-FLOWER.** *Centaurea Cyanus*.

**CORNICULATE.** Terminating in a process resembling a horn; as the fruit of *Trapa bicornis*. If there are two horns the word *dicornis* is used, if three *tricornis*, and so on.

**CORNIDIA.** A genus of trees and shrubs from Peru and Chili belonging to *Hydrangeaceæ*. They have opposite ovate or obovate stalked leaves, which are leathery and generally serrated, and bear their flowers in a terminal corymbose cyme of many

rays; calyx-tube adhering to the ovary, the limb four or five-toothed; petals four or five on an epigynous ring; stamens eight or ten; styles two to four; capsule with two or four imperfect partitions. [J. T. S.]

**CORN-SALAD.** The Lamb's lettuce, *Valerianella olitoria*.

**CORNU** (adj. **CORNUTUS**). A horn-like process, commonly solid, and usually a metamorphosed state of some other organ. Also employed in the sense of Calcar.

**CORNUCOPIÆ.** A genus of grasses belonging to the tribe *Phalarideæ*. It is distinguished chiefly by the involucre being large, one-leaved, cup-shaped or funnel-shaped, many-flowered; glumes two, united at the base, nitre-formed, and equal; pales one, bladder-shaped, split on one side, with an awn below the middle; stigmas long. Only one species is described, *C. cucullata*, the Horn of Plenty grass, a native of Greece and Asia Minor, which is frequently cultivated in gardens amongst curious annuals. [D. M.]

**CORNUELLE.** (Fr.) *Trapa natans*.

**CORNUS.** The typical genus of the order of cornels, consisting of twenty or thirty species distributed throughout temperate Europe, Asia, and America, generally forming small trees or shrubs, some, however, being humble herbs only a few inches high. Their leaves are undivided and generally opposite; their flowers have a calyx composed of four minute teeth, and a corolla of four yellow or white petals; and their fruit contains a hard two-celled stone with two seeds, and is marked at the top with a scar from the remains of the calyx.

*C. florida*, a deciduous tree about thirty feet high, is common in the woods in various parts of North America. It has shining branches, and egg-shaped sharp-pointed leaves, clothed with closely-pressed hairs on both sides; and its heads of yellowish flowers are surrounded by four large white bracts. In the United States the bark of this tree is substituted for Peruvian bark in intermittent fevers. Mixed with sulphate of iron it makes a good black ink; and the bark of the root dyes a scarlet colour. Its wood is hard, heavy, and close-grained, but being of small size it is only used for handles of tools, &c.; the young branches stripped of their bark are used for whitening the teeth.

The Cornelian Cherry, *C. mascula*, is a native of many parts of Europe and Northern Asia, forming a large shrub or small tree about fifteen or twenty feet in height, having smooth branches with oval sharp-pointed leaves, and producing its heads of small yellow flowers early in spring, before the appearance of the leaves. Its pulpy fruits resemble a cornelian in colour, and are about the size and shape of olives, for which they are sometimes substituted. The ripe fruits have a harsh acid taste, and are scarcely eatable, but they are sold in the markets in some

parts of Germany, and eaten by children, or made into sweetmeats and tarts. The Turks use the flowers in diarrhoea, and the fruits against cholera, or for flavouring sherbet. The wood is exceedingly hard and durable, and also tough and flexible; in central Europe it is used for making forks and other implements, ladder-spokes, &c., and the young branches for butcher's skewers. *C. sanguinea*, which grows wild in England, is known under the names of Dogwood, Dogberry tree, or Hound's tree, in consequence of a decoction of its bark having formerly been used for washing mangy dogs. It is a shrub about six feet high with dark red branches and broadly egg-shaped pointed leaves, which are hairy when young; and bearing heads of dull white flowers without bracts, producing globular, nearly black, and very bitter fruits, which yield an oil fit for lamps. Its hard wood is used like that of the other species, and its young branches for skewers. *C. suecica* is a humble little plant not more than six inches high, native of Britain, Northern Europe, Asia, and America. Its creeping roots produce annual stems having a few stalkless egg-shaped leaves, and terminated by a head of very minute purple flowers, surrounded by four large petal-like white bracts. The little red berries of this plant form part of the winter stock of food collected by the Esquimaux; and in the Scotch highlands they are a reputed tonic, and are supposed to increase the appetite, the plant being called *lus-a-chraois*, or Plant of gluttony. [A. S.]

Chemical analysis shows that the bark of the root, stem, and branches of *C. florida*, which are bitter, astringent and aromatic, contain, in different proportions, the same substances as are found in *Cinchona*, except that there is more gum, mucilage, gallic acid, and extractive matter, and less resin, quinine, and tannin. The principle obtained from it is called *cornine*, and its salts have, according to Dr. Blackie, all the properties of these of quinine, though not so strongly marked; the principle is also difficult to obtain in any quantity. The extract of Dogwood, though inferior and less stringent than the best cinchona, is said to be better than the inferior kinds; this extract contains all the tonic properties, while the simple resin is merely a stimulant. In cases of debility, Dogwood is a valuable corroborant. Country people often use it as a decoction, or chew the twigs as a prophylactic against fevers. Drunkards sometimes employ a tincture of the berries to restore the tone of the stomach, and combat the pangs of dyspepsia. The powdered bark of the plant makes one of the best tooth powders, as it preserves the gums hard and sound, and at the same time renders the teeth extremely white. Rubbing the fresh twigs on the teeth has this effect, and the Creoles of the West Indies, the pearly whiteness of whose teeth is universally acknowledged, use another species in this way. [T. M.]

**CORNWEED.** *Biscutula Pelecinus*.

**COROLLA** (adj. **COROLLARIS**, **COROLLINE**). That part of a flower which intervenes between the calyx and stamens; its parts are called petals.

**COROLLIFLORÆ**. A subclass of dicotyledons or Exogens, characterised by the petals being united so as to form a monopetalous corolla, inserted below the ovary, and by the stamens being usually attached to the corolla, but sometimes inserted separately below the ovary. Such orders as the heath family, the gentiana, and the labiates, may serve as illustrations. [J. H. B.]

**CORONA**. A coronet. Any appendage that intervenes between the corolla and stamens, as the cup of a daffodil, or the rays of a passion-flower. — **STAMINEA**. A coronet formed from transformed stamens.

**CORONANS**. Situated on the top or crown of anything. Thus, the limb of the calyx may crown an ovary; a gland at the apex of the filament may crown a stamen.

**CORONARIA**. A section of the caryophyllaceous genus *Lychnis*. The type of the group is the Rose Campion, *Lychnis coronaria*, a native of S. Europe, commonly cultivated for its beauty. The leaves of this plant are elliptical, white with soft wool, as are the stems and calices; corolla with the petals nearly entire, red or white, with a firm scale at the base of the limb of each; these scales form the crown. The most natural group to combine with the Rose Campion are the remaining species of the discarded genus *Agrostemma*, which have not the deeply-bifid petals of *Lychnis*: this is the arrangement of Fries. [J. T. S.]

**CORONATE**. Furnished with a coronet. Also used in the sense of Coronans.

**CORONILLA**. A genus of pretty annual or perennial plants of the pea family, characterised by the flowers being borne on stalked umbels, as well as by the articulated, round, and nearly straight pod. The plants of this genus are found in Europe, Asia Minor, and North Africa, and in greatest abundance in the countries bordering on the Mediterranean Sea. Between twenty and thirty species are enumerated. The Scorpion Senna, *C. Emersii*, a plant not unfrequently seen in gardens is a much-branched pretty bush, about five feet high. Its leaves are alternate, pinnate, from one to three inches long, and composed of three or four pairs of small wedge-shaped leaflets of a pea-green colour; these are said to produce a dye like indigo by proper fermentation, and are also reported as laxative. The yellow flowers, in their form and arrangement, are a good deal like those of the bird's-foot trefoil (*Lotus corniculatus*), and are produced in great abundance, making their appearance in May or June, and continuing in succession till the frost appears. The slender-jointed pod has been compared to a scorpion's tail. *C. varia* is a perennial plant

with creeping roots, and slender angular stems, from one to three feet long. The leaves, from two to three inches in length, have numerous oblong leaflets, and the flowers vary much in colour, being either white, rose, or violet. It grows in various parts of Southern Europe, and has been recommended as a forage plant, but its leaves are too bitter, and are even said to be poisonous. The plants of this genus bear much resemblance to each other, and in almost all, the foliage is of a peculiar pea-green colour. The yellow flowers of many emit a strong odour. [A. A. B.]

**CORONULE**. The small calyx-like body which crowns the nucule of *Chara*.

**CORPUS**. The mass of anything; thus, *C. ligneum*, or *lignosum*, signifies the mass of the woody tissue of a plant, and *C. medullare* the mass of its cellular tissue in the pith.

**CORPUSCULES**. The spore-cases of certain fungals. — **VERMIFORM**. Spiral vessels in a contracted, strangled, distorted condition.

**CORREA**. The pretty greenhouse shrubs so named are now familiar to most persons. They belong to a genus of *Rutaceæ*, and have simple dotted leaves, covered more or less with down. The handsome reddish or greenish flowers have a cup-shaped nearly entire calyx; a corolla of four petals united into a tube; eight stamens attached beneath the ovary; and four one-celled ovaries placed on a small eight-lobed disc, and covered with dense star-like hairs, the styles confluent into one. The fruit consists of four follicles bursting each by two valves, and one-seeded by abortion. These shrubs are natives of the Southern and Eastern parts of Australia, where they are sometimes called Native Fuchsias, from the slight resemblance of the blossoms to those of the fuchsia. It is said too that the leaves of some of the species are used as tea. [M. T. M.]

**CORRIGIOLA**. A genus of *Illecebraceæ*, small herbs growing in Europe (especially the Mediterranean region), and at the Cape of Good Hope. They have numerous slender slightly-branched procumbent stems, bearing linear and oblong fleshy glaucous leaves; stipules scarious, small; flowers small, green and white striped, forming compound corymbs or racemes at the end of the stem and branches: calyx five-parted, herbaceous, with a petaloid margin; petals five, very small; stamens five; style very short, three-cleft; fruit, a hard nut enclosing a single seed. *C. littoralis*, found in the extreme south-west of England, is a small annual with narrow leaves extending to the tips of the stems, and there intermixed with clusters of small flowers which arise from the axils, and also from a small terminal corymb. [J. T. S.]

**CORBOYERE**. (Fr.) *Coriaria myrtifolia*.

**CORBUGATED**, **CORRUGATIVE**. When

the parts are crumpled up irregularly, as the petals of the poppy, or the skin of some seeds.

**COR SEMINIS.** An old name for the embryo.

**CORTEX.** The bark. Also the peridium of certain fungals.

**CORTICAL INTEGUMENT.** The bark, or false bark of endogens.

**CORTICAL STRATUM.** The superficial layer of tissue in the thallus of a lichen.

**CORTICATE.** Harder externally than internally: having a rind, as the orange.

**CORTINA.** The filamentous ring of certain agarics.

**CORTINARIUS.** A large genus of *Fungi*, separated from *Agaricus* more from habit than from any striking characters. The spider-like veil, and bright red-brown spores resembling in tint that of peroxide of iron, are the most easily recognised characters. In the woods of Sweden they form by far the larger part of the mass of *Fungi*, and in our own country are sometimes very abundant. There is scarcely a single species which is received into European cookery, but in Bhotan one or two are eaten. Many of the species are extremely beautiful in point of colour, especially when young. They alter wonderfully in this respect in dry weather or as they pass maturity. [M. J. B.]

**CORTINATE, CORTINARIOS.** Having a cobweb-like texture.

**CORTISIA.** A genus referred to *Ehretiacæ*, consisting of a much-branched shrub from the Pampas of South America, having alternate sessile wedge-shaped leaves trifid at the apex, and small white tubercles on both surfaces, from which tubercles spring white hairs. Flowers solitary, sessile, generally terminal, with a tubular calyx having ten small teeth; corolla yellowish-white tubular, with a five-lobed spreading limb; stamens five exserted; style thread-like, cleft at the apex; fruit, an ovate drupe with two seeds. [J. T. S.]

**CORTUSA.** A genus of *Primulacæ*, containing a single species, a native of alpine and boreal districts in the Old World. It is a herb with the radical leaves on long petioles, and with simple scapes bearing pedicellate flowers in umbels. The calyx is five-parted; the corolla has a very short tube, and a campanulate limb; the five included stamens are inserted at the base of the limb with very short filaments and obcordate anthers; the capsule is five-valved, and many-seeded, and dehisces from the apex. [W. C.]

**CORTUSALES.** A name given by Lindley to a group of perigenous exogens, containing among others the primrose and the thrift families.

**CORYANTHES.** Under this name, formed in allusion to the resemblance of a part of the flower to a helmet, is collected a set

of epiphytal orchids inhabiting tropical America, which are the stragdest of all the strange forms of that extraordinary order. From one or two-leaved pseudobulbs hang down few-flowered racemes of flowers varying in length from two to five inches long, with the following singular structure. For the sepals there are two large membranous plates folding like a bat's wings, with a smaller interposed. In front hangs down a fleshy lip, bucket-like at the base, and expanding into a great helmet-shaped terminal lobe, whose weight keeps it always downwards, the cavity being turned upwards. The column is a long twisted recurved body with a vertical anther, containing a pair of excavated pollen masses. At the foot of the column are two fleshy feet, from whose toe perpetually distills a clear honey-like fluid, which drops into the hollow of the helmet. The meaning of so strange an apparatus is at present unexplained. Six species are known, of which *C. Fieldingi* has the largest flowers, five inches long and three wide when closed, and *C. distillatoria* the smallest.

**CORYCIUM.** A remarkable genus of orchids related to *Ceratandra*, and, like it, turning black in drying; the most marked difference between the two consisting in the petals of *Corycium* being saccate, and the lateral sepals connate, so as to form a narrow concave lower lip. Nine or ten species have been described, all inhabiting the Cape of Good Hope, and having close spikes of purplish or greenish flowers. One of them, *Corycium orobanchoides*, has been in cultivation.

**CORYDALIS.** A genus of *Fumariacæ*, containing succulent-stemmed herbs, natives of the Northern Hemisphere. They have ternate or twice ternate leaves, and racemose flowers, which are very irregular. Calyx of two lateral sepals; corolla of four petals, the upper one spurred or gibbous at its base; stamens six, in two bundles of three each, the filaments forming a ribbon which is three-cleft at the end, the middle lobe with a two-celled, the others each with a one-celled anther; a spur-like process projects backwards from the upper ribbon, and is received into the hollow space of the upper petal. The capsule is a two-valved one-celled pod with numerous seeds, which have an appendage at the hilum. The genus is divided into several sections:—*Cepitæ* with no thickened tuberous rootstock. *Bulbocapnos* with a roundish or ovoid enlarged rootstock and alternate leaves. *Cryptoceras* with a fusiform rootstock and opposite leaves. [J. T. S.]

**CORYDALIS, CLIMBING.** An American name for *Adiantum*.

**CORYDANDRA.** *Eulophia*.

**CORYLACEÆ.** (*Cupulifera*, *Castanea*, *Quercinea*, *Mastuoidea*.) A natural order of monochlamydeous dicotyledons, belonging to Lindley's quernal alliance. Trees or shrubs bearing catkins, with simple, alternate, stipulate, often feather-veined leaves,

and frequently staminate and pistillate (monoecious) flowers. Barren flowers (staminate) in catkins; stamens five to twenty, inserted in the base of scales, or of a membranous valvate perianth. Fertile flowers (pistillate) aggregate, or in a spike. Ovary with several cells, enclosed in an involucre or cup (cupule); ovules in pairs or solitary; stigmas, several. Fruit a nut with a husk or cup; seed solitary, without albumen. The plants abound in the forests of temperate regions in the form of oaks, hazels, beeches, and chestnuts. They afford valuable timber and edible seeds, and their bark is astringent. *Quercus* includes the various species of oak, which are well characterised by their acorns. Lieberman says that there are 230 species of oaks known, belonging chiefly to the Northern Hemisphere. To the south of the Line they occur in the Sunda Islands. They are not met with in the temperate zone of the Southern Hemisphere. *Quercus pedunculata* or *Robur* is the common British oak, which has usually stalked acorns. *Q. sessiliflora* is the Durmast with sessile fruit, which by some is reckoned only a variety of the former. The Durmast furnishes the best timber. In the common oak the medullary rays are large and the wood is easily rent; in the Durmast the rays are small and the wood not easily rent. Common oak taken from a ship broke under an average weight of 331 lbs., only bending  $4\frac{1}{2}$  inches; while Durmast from the same ship broke with an average weight of 1,032 lbs., and deflected 5½ inches before breaking. Durmast grows faster than common oak, and it was used in many ancient buildings, as in Glasgow Cathedral. The cups of *Quercus Egilops* are used by dyers under the name of valonia. The outer bark of *Quercus Suber* supplies cork. *Corylus Avellana*, the common hazel, yields excellent charcoal for drawing. *Fagus sylvatica*, the beech, and *Castanea vulgaris*, the Spanish chestnut, are cultivated for timber. *Castanea chrysophylla* is the golden chestnut from Oregon. There are eight or nine known genera, and about 280 species. Illustrative genera:—*Corylus*, *Carpinus*, *Fagus*, *Castanea*, *Quercus*. [J. H. B.]

**CORYLOPSIS.** The name of a genus belonging to the order of Witch-hazels, characterised by the calyx being adherent to the ovary, and divided above into five unequal pieces; corolla of five pieces, broadest upwards; filaments or stalks of the stamens awl-shaped and free; five short scales in the spaces between the stamens; styles or appendages on the ovary two in number, each thickest at the base, and ending in a round head or stigma. The name is derived from the Greek, and means 'hazel-like,' indicating the general habit of the species, which are shrubs, natives of Japan, with alternate stalked leaves, heart-shaped or entire at the base and of short duration; the flowers are yellow. [G. D.]

**CORYLUS.** A small tree belonging to the *Corylaceæ*, and under the name of Hazel too well known to need any state-

ment of the characters by which it may be identified. The usual form of the Hazel in its wild state is a straggling bush consisting of a number of long flexible stems from the same root. The bark on the young branches is ash-coloured and hairy, that on the old stems mottled with bright brown and gray. *C. Avellana* includes not only the hazel, but all the European varieties of filbert and cobnut. Among the wild animals which feed on these nuts the most destructive are the squirrel, which carries them off for a winter hoard, or demolishes them on the spot, splitting the shell into two halves; the dormouse, which climbs the trees, and nibbles a round even hole, extracting the contents piece-meal; and the nuthatch, a bird not much bigger than a sparrow, belonging to the tribe Scansores, which carries them off singly, and fixing them in the crevice of an oak or some other rough-barked tree takes his position above, and, head downwards, hammers away with his strong beak until he has made an irregular angular hole. Many nuts are also rendered worthless by a beautiful little beetle (*Balaninus nucum*), which in early summer lays within the tender shell of a nut a single egg, which when the kernel is approaching maturity is hatched into a small grub. This, when the period of transformation to the pupa state is approaching, eats its way through the shell, and falling to the ground buries itself and constructs a cell from which it comes forth in the following season as a perfect insect. The hazel is rarely found of sufficient size to supply building materials, but the young rods being tough and flexible are much used for hoops, walking-sticks, fishing-rods, &c.; and from their smoothness and pleasing colour they are well adapted for making rustic seats and tables for summer-houses; they are also good fire-wood. The charcoal crayons used by artists for drawing outline are also prepared from hazel-wood. A purple-leaved variety to be obtained at the nurseries is a great ornament to shrubberies. Other species occasionally cultivated in England are *C. tubulosa* from Europe, *C. americana* and *rostrata* from America, and *C. Cohnra* from Turkey. French, *Noisetier*; German, *Hasselstande*. [C. A. J.]

The name of *Avellana* is said by Pliny, according to Prof. Targioni, to be derived from Abellina in Asia, supposed to be the Valley of Damascus, its native country. He adds that it had been brought into Greece from Pontus, hence it was also called *Nux pontica*. The nuts were called, by Theophrastus, Heracleotic nuts, from Heraclea, now Ponderachi, on the Asiatic shores of the Black Sea. Others admit that a variety of hazel nut or filbert was brought from Pontus to Abella, a town in Campania, and hence the name of *Avellana* was applied to these trees. In France, at the present day, the better varieties are called *Avellanes*. But the above indications of an Eastern origin can only refer to particular kinds, for the species, it is well known, is common enough in Italy, as well as in other parts of Europe. It is also found over

a great part of Asia in a wild indigenous state. It bears the common names of Hazel, Hazle, or Hazel, not only in this country, but also in Germany, Holland, Sweden, and Denmark. The plant is indigenous to all these countries. Its habitat extends from the extreme south of Europe to the most northern parts of Britain. According to De Candolle it is found wild in the mountains of the Island of Sardinia; and he is not certain whether its growth may not be natural in some ravines near Algiers. It is said to be not now found in Shetland; but formerly it had existed there, for the shells of its nuts are found plentifully in bogs, as they are likewise in similar places throughout Scotland. The ancient nut-shells are often met with in fragments, but many are found quite entire, at various depths below the surface; some of them are larger than those of the Wild Hazel, growing near the same localities at the present day.

The Hazel generally forms large bushes, from its great disposition to produce suckers; but if grown with a single stem it assumes the form of a low tree. One at Gordon Castle, North Britain, measured thirty feet in height, with a trunk three feet in circumference. The plants often form a sort of jungle on precipitous banks of rivers and streams, and may frequently be seen growing out of crevices and fissures of rocks, sometimes much confined for root-space, yet in that case roots will extend far downwards, naked along the face of the rock, till they reach soil below. The wood when two years old and upwards is tough and elastic, and it is well adapted for hurdles, crates, hoops, walking-sticks, &c. Its charcoal is esteemed for making gunpowder.

Nut leaves are large, roundish cordate, and somewhat pointed. The same tree bears male and female flowers, distinct from each other, proceeding from different buds. The male flowers begin to make their appearance in autumn, and acquire their full development early in spring; they are at first compact cylindrical bodies of a greyish colour, afterwards they become long pendulous catkins of a yellow colour, giving the trees, then destitute of leaves, a conspicuous and rather ornamental appearance. The female flowers do not appear till spring. They exhibit a few crimson thread-like styles issuing from the apex of a bud. This bud elongates, and forms a small bruchlet, at the extremity of which the cluster of nuts is borne. Until the nuts are nearly full-sized their yet soft green shell is filled with a milky juice, but this does not constitute the kernel. The latter may be observed at the same time not larger than the head of a pin. As it grows the milky substance is absorbed, all except the fibrous portion, which is deposited on the inside of the shell, forming a soft lining for the kernel. The calyx or husk has a fleshy base, to which the lower part of the nut is strongly attached until fully ripe, when the husk dries up and permits the nut to drop out, except in the case of some varieties, more especially those called fil-

berts, which have long tubular husks contracted beyond the apex of the nuts. These were formerly called Full-beards, whilst those with short husks were simply termed Nuts or Hazel-nuts.

There are numerous varieties, differing in the form of the nuts, and in the relative length of their husks. The Red Filbert and White Filbert are similar in external appearance, but in the former the thin pellicle which forms the immediate coating of the kernel is red or crimson, that of the latter white or pale-brown. Both these are esteemed because they admit of being kept fresh in the husks. Short roundish nuts with a strong thick shell are called Cob nuts. Of this description are most of those imported from Spain. The Coford nut is of an oblong form with a comparatively thin tender shell, finely striated longitudinally. The sorts above-named, together with the Downton large square nut, and the large Spanish, are amongst the best sorts for cultivation.

In this country, the neighbourhood of Maidstone in Kent is the most celebrated for the cultivation of filberts. The foreign supply is chiefly from Spain. Phillips states that from a single wood near Recus, 60,000 bushels have been gathered in one year, and shipped from Barcelona, whence they are called Barcelona nuts. 'In the neighbourhood of Avelino in Italy,' says Swinburn, 'the whole face of the neighbouring valley is covered with nut trees, and in good years they yield a profit of 80,000 ducats.' According to French authors the nuts of Provence and Italy are preferable to those of Spain and the Levant. [R. T.]

The common Hazel, *C. Avellana*, is the badge of the clan Colquhoun.

**CORYMB** (adj. **CORYMBOSE**). A raceme, whose pedicles are gradually shorter as they approach the summit, so that the result is a flat-headed inflorescence, as in candy-tuft. — **COMPOUND**. A branched corymb, each of whose divisions is corymbose.

**CORYMBIFERÆ**. Corymb-bearing composite plants, a sub-order of the natural order *Compositæ* or *Asteracæ*, containing plants with numerous flowers on a common receptacle, forming a head surrounded by a set of floral leaves or bracts called an involucre. The heads of flowers are either placed singly on stalks; or there are several stalked heads supported on a common axis, and so arranged as to have collectively the form of a corymb, the lower stalks being longer so as to bring the heads to nearly the same level. The flowers in the circumference of the heads are usually ligulate and bear pistils only, while those of the centre are tubular and have both stamens and pistils. The style of the perfect flowers is not swollen below the stigma. Such plants as chamomile, the daisy, the ox-eye, the dahlia, everlasting, sunflower, cineraria, ragwort, and groundsel belong to this sub-order. The plants have bitter qualities; some of

them induce sleep, and they usually contain more or less of a volatile oil. [J. H. B.]

**CORYMBIS.** Under this name, and those of *Corymborchia*, *Centrosia*, *Rhynchospora*, *Macrostylis*, and *Hysteria*, botanists have described a singular herbaceous orchid found in the tropical parts of Africa and Asia, with the habit of a small bamboo, and long slender white flowers. After flowering the column grows to a great length, with the remains of the other organs at the base. Only one species, *C. disticha*, is well known; two others very like it are described.

**CORYMBIUM.** A genus of S. African plants of the composite family, some of them common on the flats about Cape Town, and on Table Mountain. They are perennial plants about two feet high, with grassy root leaves, which have parallel nerves, and are furnished at the base with a tuft of woolly hairs. The stem bears a number of small linear leaves, and terminates in a dense corymb of flowerheads, each of which contains but a single floret in a circumstance unusual in the family. The achene is clothed with long soft hairs, and crowned by a pappus of short scales. [A. A. B.]

**CORYNEPHORUS.** A genus of grasses belonging to the tribe *Avenae*. It is not considered essentially distinct from *Aira*, under which it is described in *Steudel's Synopsis*, as the *Aira caenaceus* of Linnaeus. It is rare in England, but generally diffused throughout Continental Europe. [D. M.]

**CORYNEUM.** One of the most remarkable genera amongst the coniomycetous *Fungi*, distinguished by the dark naked elongated articulated spores, radiating in every direction from a little raised cushion-like receptacle. It is distinguished from *Hendersonia*, which has somewhat similar spores, by the absence of any surrounding cyst or perithecium. From *Bacridium* it is separated by its more developed receptacle and dark, not coloured spores. The species grow on dead twigs. *C. Kunzei*, which is not uncommon on oak, affords a pretty microscopical object. The species are now, however, considered as conidiferous forms of *Sphaeriaceae* genera. [M. J. B.]

**CORYNIDIA.** Processes sunk into the margin of the germinating leaf of ferns, and containing spiral threads.

**CORYNOCARPUS.** A New Zealand genus of handsome trees belonging to the order *Myrsinaceae*. The leaves are entire and smooth; and the flowers small, white, in terminal clusters. The sepals and petals are five in number, the latter provided with a narrow claw; alternating with the petals are five ascending scales, each with a small globular gland attached to it; there are five stamens; the ovary is globular. The fruit is club-shaped, hence the name of the genus; it contains but one seed. *C. levis* is in cultivation in this country. The tree, according to Dr. Bennett, is valued in New Zealand for the sake of its fruit and seeds; the former is of the size

of a plum, pulpy in the interior and sweet. The seeds are used in times of scarcity, and contain a tasteless farinaceous substance. The raw seeds, however, are poisonous, and produce spasmodic pains, giddiness, and partial paralysis, to obviate which effects they are steamed for twenty-four hours, and then either buried in the ground, or allowed to soak in water for some days. [M. T. M.]

**CORYNOSTYLIS.** Tropical American climbing shrubs of the violet family, with entire saw-toothed leaves, deciduous stipules, and large handsome flowers. The sepals are nearly equal; the five petals very irregular, the anterior ones the smallest, the lateral ones erect, the hinder one very large and prolonged at the base into a spur; the five stamens have short filaments prolonged into a hairy appendage at the base, the anthers surmounted by a membranous crest; the ovary is somewhat globular, three-celled; the style terminal, club-shaped; the stigma ciliated, lateral; the fruit a capsule with many seeds. [M. T. M.]

**CORYPHA.** A genus of fan-leaved palms composed of about five species, all natives of tropical Asia, and mostly forming tall trees. All their flowers are perfect, and produced on branching spikes, which are surrounded at the base by numerous leafy bracts. They have a cup-shaped calyx, the rim of which is cut into three teeth; a three-petaled corolla; six stamens, whose bases are dilated so as to join one another; and three ovaries, which cohere, and have their awl-shaped styles united together and crowned by a simple stigma. The fruit is a one-seeded berry.

The Talipot palm, *C. umbraclifera*, is a native of Ceylon and the Malabar coast, where it grows to sixty or seventy feet high, with a straight cylindrical trunk, marked by rings, and surmounted by a crown of gigantic fan-like leaves. These leaves have prickly stalks six or seven feet long, and when fully expanded form a nearly complete circle of thirteen feet in diameter, and composed of from ninety to a hundred radiating segments, joined together and plaited like a fan till near the extremity, where they separate and form a fringe of double points. Large fans made of these leaves are carried before people of rank among the Cinghalese; they are also commonly used as umbrellas, and tents are made by neatly joining them together; besides which they are used by the natives as a substitute for paper, being written upon with a style. Some of the sacred books of the Cinghalese are composed of strips of them. The hard seeds are suitable for turnery purposes. *C. Taliera* is a native of India, and is closely allied to the preceding, but does not grow more than thirty feet high. Its leaves are used for the same purposes. *C. Gebanga* is called Gebang in Java, where it is a native. The leaves are used for thatching, plaiting into baskets, hats, and similar articles. From the interior of the trunk a kind of sago is obtained; and the sliced

root is said to be an efficacious remedy for diarrhoea. [A. S.]

**CORYSANTHES.** Curious little swamp orchids, inhabiting Australia and Java, have received this name in allusion to their large dorsal sepal having the form of a helmet. They have thin roundish solitary leaves, from the axil of which rises a single purple and green flower. One species, named *Calcearia* by Blume, grows among damp moss on the summit of Mount Salak in Java.

**COSCIINIUM.** A remarkable genus of *Menispermaceæ*, characterised by its large petals, the irregularly-mottled albumen, and the structure of its embryo, which has its radicle superior, pointing towards the apex of the drupe-like fruit, while the cotyledons are rounded, widely-spreading, either perforated with holes, or, according to Miers, deeply-gashed; but they are so thin as not readily to be taken from the albumen on which they lie. *C. fenestratum*, formerly called *Menispermum fenestratum*, is considered in Ceylon to be a valuable stomachic and tonic. The wood, which has a peculiar structure, described in Hooker and Thomson's *Flora Indica*, is of a yellow colour, and yields a yellow dye. Medicinally the wood, bark, and root, are used as tonics. [M. T. M.]

**COSMANTHUS.** A small genus of annual hydrophylls, closely allied to *Eutoca* and *Phacelia*, so closely in fact, that by some botanists both *Eutoca* and *Cosmanthus* are regarded as only sections of the genus *Phacelia*. It scarcely differs from the latter, but in its fringed corolla and procumbent habit; from *Eutoca* it is distinguished by the former character, and by its fewer and larger seeds. The only species at all known in this country, *C. flabiniata*, and which may serve as a type of the genus, is a neat procumbent plant, with rather succulent branched angular spreading stems, pinnatifid leaves, those of the stem stalkless and stem-clasping, those at the root on long stalks, all with ovate entire lobes; it has very pale lilac purple flowers produced in a curled or crook-like raceme, the corolla wheel-shaped, and having at the base of each lobe a scale rolled into a tubular form; five linear calyx segments, five stamens with hairy filaments, a single style with a circle of hairs at its base, and a four-seeded pod, complete the description. The species are all natives of North America, and appear to be destitute of any marked properties. [W. T.]

**COSMILIA.** A genus of *Euphorbiaceæ*, containing but one species, an erect marshy plant, with glossy leaves sheathing the stem, and solitary reddish flowers at the termination of the short branches. The foliaceous calyx is surrounded with many imbricated bracts; the corolla is five-parted; the anthers are exserted; there are five hypogynous scales; the capsule is five-valved and many-seeded. It is a native of S. W. Australia. [W. C.]

**COSMIDIUM.** A genus of composites, recently separated from *Coreopsis*, from which it differs in having an elongated obscurely four-angled, and minutely mamillated fruit, crowned by two short thick horns, and partially enveloped in a membranous scale, which remains attached when the fruit separates from the receptacle. In general habit and aspect, the species approach very closely to *Calliopsis*, having, like that, smooth erect branched stems, opposite leaves, pinnatifidly cut into distinct thread-like segments, and flower-heads an inch and half in diameter, with a ray of about eight broadly wedge-shaped florets, and a double involucre surrounding the capitule, each series consisting of eight leaflets, the innermost broad and erect, the outer narrow, spur-like and spreading. *C. filifolium*, till recently the only species generally known or cultivated, has the ray florets yellow, and the disk or centre crimson-brown. The beautiful *C. Burindegnum*, of gardens, which is perhaps but a variety of the preceding, has larger flower-heads, with the ray florets of a deep purple brown at their base, the tip only being orange yellow. The fruit of this plant is considerably shorter and thicker than in *C. filifolium*. [W. T.]

**COSMOPHYLLUM.** The name given to a genus of the composite family found in Guatemala. *C. coccineifolium* is the only known species; it is described as a shrub or small tree, with leaves one to two feet in length, oval in contour, with seven triangular lobes, and having their surface clothed with short white down. The flower heads have some resemblance to those of the chamomile, and are disposed in terminal corymbs; the outer florets are white, strap-shaped and contain a pistil only; the inner are yellow, tubular, and perfect. The four-sided achenes bear on their angles rough points, and are crowned with a hard short pappus composed of a number of unequal-cut scales. [A. A. B.]

**COSMOS.** A small genus of composites allied to *Bidens*, with large showy reddish-purple or yellow flower heads, and finely divided or pinnate foliage. They are better known in gardens by Willdenow's name of *Cosmea*, but *Cosmos* has priority in its favour. The genus has a double involucre, as in *Coreopsis*, each series composed of from eight to ten ovate leaflets, the outer ones spreading, the inner ones erect; the receptacle is flat and set with membranous coloured scales, drawn out to a thread-like point; and the fruit is four-angled, tapering to both ends, and crowned with from two to four deciduous barbed awns. *C. bipinnatus* is a handsome annual, attaining in moist soil a height of four or five feet, with a smoothish erect furrowed stem, spreadingly-branched; opposite bipinnate leaves, the segments of which are linear, pointed, and somewhat curled; and flower heads two inches or more in diameter, on long peduncles, the ray florets about eight in number, of a bright red purple, the disk being composed of yellow florets tubular,

The fruit of the species is smooth and usually furnished with three awns; but that of *C. tenuifolius*, a dwarfier species with more finely-divided foliage, and darker flowers, is rough, and more frequently has but a single awn. All the species are natives of Mexico. Under the name of *Dahlia Zimapani*, a new species, *C. diversifolius atropurpureus*, has recently been introduced, with pinnate dahlia-like foliage, and flower heads varying from blackish-purple to red-purple, on very long peduncles, the disk being of the same colour as the ray florets. [W. T.]

**COSMOTIGMA.** A genus of *Asclepiadaceae* containing a single species, a branched twining shrub, that climbs over trees of great height in India. It has opposite leaves with conic glands at their base, and many small flowers in racemes on interpetiolar peduncles. The small calyx is five-parted; the corolla is rotate and five-parted; the staminal corona consists of five blind divisions, which are irregularly toothed on their upper and inner margins; the anthers are terminated by a broad membrane; the oval pollen masses attached by long-kneed processes to a small bifurcate corpuscle; the follicles are large, linear, oblong, and smooth, with ovate comose seeds. [W. C.]

**COSSIGNIA.** A genus of *Sapindaceae*, differing from the others in the family in having flowers with petals, together with a capsular but not bladderly fruit, which is three-celled, each cell containing two or three small black seeds. The two known plants of this genus are natives of the Mauritius, where they are known as Bois de Judas. They are small trees with pinnate leaves made up of one or three pairs of oblong or oboval entire leaflets and an odd one; these are about two inches long, smooth above, and covered underneath (as are all the young parts) with a short white down. The small white flowers, disposed in terminal panicles, have a five-parted calyx, four or five oval petals larger than the calyx, and a like number of stamens inserted on a disc. The three-lobed ovary is crowned with a single style. [A. A. B.]

**COSTA.** The midrib of a leaf; that part which is a direct extension of the petiole, and whence the veins arise; a leaf may have many costae.

**COSTATE.** When there is only one rib, as in most leaves. Also the mere adj. of costa.

**COSTATO-VEBOSE.** When the parallel side-veins of a feather-veined leaf are much stouter than those which intervene.

**COSTMARY.** *Pyrrethrum Tanacetum*, sometimes called *Balsamita vulgaris*.

**COSTUS.** A genus of tropical herbs belonging to the *Zingiberaceae*, and having tuberosus roots, somewhat fleshy leaves, and flowers in spikes with overlapping bracts. The calyx is tubular and three-cleft; the tube of the corolla is funnel-shaped, the

outer segments of the limb equal, the inner lateral ones (sterile stamens) wanting, while the innermost or middle segment, called the lip or labellum, is large, bell-shaped, cleft at the back; the filaments are petaloid, prolonged beyond the anther on all sides. Ovary with three compartments; the style thread-like, passing between the cells of the anther; the stigma two-cleft, with two small horns at the base. Many of the species are highly ornamental as stove plants, such as *C. spectosus*, the roots of which are used by the natives in a kind of preserve. [M. T. M.]

**COSTUS.** The roots of an Arabian plant, supposed to be allied to *Cardopuntium corymbosum*. The Costus of the ancients has, however, been ascertained to be the root of *Aucklandia Costus*, now *Spiloxzis Lappa*.

**COTONEASTER.** A family of small trees or trailing shrubs belonging to the order *Rosaceae*, and allied to *Mezplus*, inhabiting the northern parts of Europe and the mountains of India. The leaves are small and entire at the edge, downy beneath, in some species evergreen; the flowers, which are white or pinkish, grow either in lateral clusters, like those of the hawthorn, or singly, and are succeeded by scarlet, or less commonly black, berry-like fruit. The species are very desirable from the beauty of their foliage, flowers, and fruit; the fruits of *C. frigida* and *C. affinis*, in particular, being produced in great abundance, and being of an intense scarlet colour, have a very splendid appearance, and remain on the trees the greater part of the winter. Though the greater part are natives of Asia, yet in Britain they are found to be as hardy as if they were indigenous to the north of Europe, especially such of them as are true evergreens. *C. vulgaris*, a species with deciduous leaves, has been in cultivation in British gardens since 1656, and was always considered a foreign plant, till it was found in a wild state at Orme's Head in Carnarvonshire.—(Loudon). *C. microphylla* is a yet more valuable plant. In this species the branches are trailing, the leaves small and evergreen. It is perfectly hardy and, wherever it grows, ornamental. 'Its deep glossy foliage, which no cold will impair, is, when the plant is in blossom, strewed with snow-white flowers, which, reposing on a rich couch of green, have so brilliant an appearance, that a poet would compare them to diamonds lying on a bed of emeralds.'—(Lindley). *C. marginata, rotundifolia* and *buxifolia*, are of similar habit. The last species were introduced from the hills of Hindostan in 1824 and 1825. [C. A. J.]

**COTONNIER.** (Fr.) *Gossypium*.

**COTTON.** This well-known valuable textile commodity is the hairy covering of the seeds of *Gossypium herbaceum* and other species of *Gossypium*, especially of *G. religiosum, barbadense, indicum, and arboreum*. —, **CORKWOOD.** A name given in Trinidad to the down of *Ochroma Lago-*

*pus.* —, NATAL. A textile material resembling true cotton, obtained from the pods of a species of *Batatas*. —, SILK. A common name for *Bombax*. *B. pentandrum* is called the Indian cotton-tree.

*COTTONIA macrostachya* is an orchideous epiphyte from the Madras presidency and Ceylon, with a few greenish purple-lipped flowers at the end of a long lateral slender peduncle. The foliage is that of a *Succolabium* or *Vanda*, so that the name of *V. peduncularis* has been applied to the plant. Another species, *C. Championi*, found on both Victoria Peak Hong Kong, and the Khasya mountains, has smaller dirty lemon-coloured flowers in racemes little longer than the distichous leaves, which are mucronate and even serrate at the point.

**COTTON-GRASS.** The common name for *Eriophorum*.

**COTTON-ROSE.** A common name for *Flago*.

**COTTON-RUSH.** A name sometimes given to *Eriophorum*.

**COTTON-SEGE.** A name given by Bentham to *Eriophorum*.

**COTTON-THISTLE.** A common name for *Onopordum*.

**COTTON-WEED.** *Diotts maritima*.

**COTTON-WOOD.** An American name for *Populus monilifera* and *P. angulata*.

**COTULA.** A genus of weedy compound flowers allied to *Anthemis*, from which it is distinguished by its hemispherical naked receptacle, four-cleft florets of the disk, and by the ray being almost wanting. There are numerous species, of which one only, *C. coronopifolia*, is found in Europe. There is no British example. *Cotula* is a diminutive of *Cota*, the old name of some species of *Anthemis*. [C. A. J.]

**COTYLEDON.** A genus of shrubs and herbaceous plants belonging to the *Cruasulaceae*, among which they are distinguished by their five sepals, tubular five-cleft corolla bearing ten stamens, and a scale at the base of each of the five carpels. The only British species, *C. Umbilicus*, Navelwort, or Penny-wort, is a common weed in the west of England and some parts of Wales and elsewhere, growing on the sides or in the crevices of damp rocks and walls, where it is conspicuous during the winter and spring months by its orbicular concave petiole exceedingly succulent leaves, called by children Penny-pies. In summer it sends up a stalk, the lower portion of which bears succulent leaves, which gradually lose their petiole form and pass into bracts. The stalk, when the plant grows in a dry situation, is from four to six inches long, and bears a simple spike of drooping green flowers; but in a more genial situation grows to the height of a foot or more and is branched. After the seeds have ripened, the stems wither and turn brownish red, but retain their form

during a great part of the winter. Of the foreign species several are natives of the Cape of Good Hope; these are evergreen under-shrubs, and are sometimes found in the green-houses of the curious. *C. orbiculata*, which is the one most frequently cultivated, has thick and succulent leaves tinged at the edge with purple. The flowers are large drooping, and have the divisions revolute and of a reddish hue; they last from June to September. *C. lutea* is by some authors enumerated among British plants, but without due grounds. It is a native of Portugal. [C. A. J.]

**COTYLEDONS.** The seed-lobes; the primordial leaves in the rudimentary plant or embryo.

**COTYLIFORM.** Dished. Resembling rotate, but with an erect limb.

**COUCH-GRASS.** *Triticum repens*.

**COUCOU.** (Fr.) *Primula officinalis*.

**COUCOURZELLE.** (Fr.) A kind of gourd.

**COUDRIER.** (Fr.) *Corylus Avellana*. — **DU LEVANT.** *Corylus Colurna*.

**COUEPIA.** A genus of the chrysobalan family, whose distinguishing characters are its one-celled ovary, which adheres to the calyx tube, and its numerous stamens (twenty to forty or more), which arise from one side only of the mouth of the calyx, or are disposed round it in a perfect ring. The genus comprises upwards of a dozen species, all of them trees of South America, generally small, but sometimes attaining a height of fifty feet. Their leaves are entire, usually oblong, and very often covered with short white down underneath. The flowers, numerous and seldom more than half an inch in diameter, are either white or cream-coloured, and when in bud have a shape exactly like that of a clove; they are disposed in terminal or axillary panicles or racemes, and are composed of a tubular calyx with a five-parted border, five petals, numerous stamens, and an ovary with a simple style arising from near its base. The oval stoned fruits of a number of species are eaten. *C. chrysocalyx* is a beautiful tree of a pyramidal form, branching to the base, and attaining a height of thirty feet. According to Mr. Spruce, it grows plentifully all along the Amazon river from the Barra upwards. The Indians plant it also near their houses for the sake of its edible fruits, and a large pueblo on the Marañon of Cucama Indians derives its name 'Parauari' from the abundance of this tree, so called. Its oblong pointed or blunt leaves have a smooth upper surface, and are covered underneath with short white down. The flowers, about an inch in length, have a calyx covered with yellow down, and are borne in axillary racemes much shorter than the leaves. *C. guianensis* is, according to Aublet, a tree of sixty feet high, with grey shining bark, and dark red-coloured wood, which is durable and heavy. The leaves are oval, acute, and

stalked. The Indians make use of the bark in the manufacture of their pottery. The Caribbean name of the tree is Copepl, whence the origin of the generic name. *C. bracteata*, a Brazilian tree forty feet high with leaves half a foot long, and panicles of flowers furnished with large bracteas, is remarkable in the family, according to Mr. Spruce, for the fetid odour of its cream-coloured flowers. [A. A. B.]

**COUGOURDETTE.** (Fr.) *Cucurbita ovifera*.

**COULEUVRE'E.** (Fr.) *Bryonia dioica*.

**COUMARIN.** The fragrant principle of the Tonka bean, *Dipteris odorata*, and also of *Melilotus corallius*, the latter of which gives its peculiar odour to Chappizger cheese.

**COUNTRYMAN'S TREACLE.** An old name for *Ruta graveolens*.

**COURGE.** (Fr.) *Cucurbita maxima*. — **DE SAINT-JEAN.** *Cucurbita Pepo*. — **VIVACE.** *Cucurbita perennis*.

**COURONNE DES BLE'S.** (Fr.) *Agrostemma Githago*. — **IMPERIALE.** *Fritularia Imperialis*.

**COURROUPITA.** A genus of trees belonging to the order *Lecythidaceae*, and natives of tropical America. The clusters of flowers spring from the trunk and branches. The flowers are large whitish or rose coloured, with a top-shaped calyx-tube, adherent to the ovary, its limb having six deciduous segments; the corolla consists of six petals inserted into a disc, which surrounds the top of the ovary; the cup formed by the union of the filaments of some of the stamens is inserted with the petals; on one side it is very short, on the other it is prolonged into a petal-like hood overlapping the style, and bearing anthers at its top; the stamens at the base of the cup are minute and barren, those at the apex of the petal-like hood are fertile; ovary with six compartments; stigma sessile, hexagonal. The fruit is large, globular, and woody, marked with a circular scar indicating the point of detachment of the limb of the calyx; the seeds are numerous and imbedded in pulp. The fruit of *C. guianensis* is called from its appearance the Cannon-ball fruit. Its shell is used as a drinking vessel, and its pulp when fresh is of an agreeable flavour. [M. T. M.]

**COURY.** A kind of Catechu, obtained by evaporating a decoction of the nuts of *Areca Catechu*.

**COUSINIA.** A genus of prickly-leaved thistle-like plants of the composite family, found in Western Asia, occurring as far east as Kunawur in the Himalaya, having their western limit in Asia Minor and found in greatest numbers in Persia. They are nearly allied to *Carlinia*, but differ in having a simple-haired, not feathery, pappus. Upwards of thirty species are enumerated, some of which are annual, others perennial; some dwarf and prostrate, others tall and erect. The root leaves of many

are pinnately-parted, with spiny segments, and covered, especially underneath, with a loose white cottony substance; those of the stem, similarly cut and spiny, often have their bases decurrent, which gives the stem a winged appearance. Others have leaves, which in size and form are not unlike those of the holly. The flower-heads are either large and few on the ends of the branches, or numerous and small; their involucre, made up of many spiny-pointed scales, enclose a great number of yellow or pink florets. The achenes are smooth, or have rough points, or longitudinal furrows, and in some cases they are compressed and angled. The pappus is composed of two or three series of short and unequal rough hairs. [A. A. B.]

**COUSSAPOA.** A genus of tropical American trees, abounding in a milky juice, and belonging to the family *Artocarpaceae*. The trees are described as being at first mere climbing shrubs, but after reaching the summit of the tree upon which they are supported, they send down branches into the earth, these branches becoming fused together so as to encircle completely the tree which originally sustained them, and cause its death. The branches are spongy in texture, and hollow in the interior. The flowers are dioecious and clustered in heads, the male flower encircled by three or four small bracts, and consisting of a tubular perianth, from whose base two conjoined stamens arise; the female flower without bractlets surrounding its perianth, and consisting of four leaflets in close approximation. The one-celled ovary becomes succulent when mature, as also does the fleshy perianth, so that a mulberry-like fruit is produced. [M. T. M.]

**COUSSINET.** (Fr.) *Oxycooccus palustris*.

**COUTAREA.** A genus of cinchonaceous trees inhabiting Guiana, &c., and having large whitish flowers. The corolla is funnel-shaped, its tube short, so that the six stamens project from it, and its limb six-parted. The fruit is a leathery capsule, bursting by two valves, and containing several kidney-shaped seeds. *C. speciosa* is a very handsome stove plant; its bark is used in Guiana as a substitute for cinchona. It is also known by the name of *Portlandia hexandra*. [M. T. M.]

**COVENTRY BELLS.** *Campanula Medium*, also called Canterbury Bells.

**COWAGE.** The Cow-itch, *Mucuna pruriens*.

**COWANIA.** A genus of the rosewort family, distinguished from its congeners by the ten-cleft calyx; corolla of five petals; seed vessels five to ten, closely covered with fine down, and when ripe, each crowned with a feathery appendage, consisting of the enlarged persistent style. The genus was named by David Don in honour of Mr. Cowan, who, in the course of visits to Mexico and Peru, introduced many plants of those countries into Britain. *C. pilosa* or *mexicana*, the best-known species, is an inter-

esting shrub, about two feet high when mature, with alternate small narrow leaves, the edges turned down, covered with glands on the upper surface, and on the lower, white with fine down. The flowers are numerous and of a yellow colour, very much resembling those of certain species of *Potentilla*. [G. D.]

**COWBANE.** *Cicula virosa*; also an American name for *Archemora*.

**COWBERRY.** *Vaccinium Vitis idæa*. The name Cowberry is also applied in some parts of Scotland to the fruits of *Comarum palustre*.

**COW-GRASS.** *Trifolium medium*.

**COWHAGE-CHERRY.** The fruit of *Malpighia urens*.

**COW-HERB.** *Saponaria Vaccaria*.

**COWITCH, COWAGE, or COWHAGE.** The hairs of the pods of *Mucuna pruriens*, which are used as a mechanical antihelmintic.

**COW-PARSLEY.** *Heracleum Panacis*; also commonly applied to *Chærophyllum sylvestre*.

**COW-PARSNIP.** A common name for any *Heracleum*.

**COW-PLANT, CEYLON.** *Gymnema lactiferum*.

**COW-QUAKES.** *Briza media*.

**COWRIE PINE.** *Dumbara australis*.

**COWSLIP.** *Prinula veris*. — **AMERICAN.** The common name for *Dodecatheon*. — **VIRGINIAN.** *Mertensia* or *Pulmonaria virginica*. — **JERUSALEM.** *Pulmonaria officinalis*.

**COW-TREE.** The Palo de Vaca of South America, *Brosimum Galactodendron*, sometimes called *Galactodendron utile*; also the Hya Hya of the same continent, *Tabernaemontana utilis*. The name has besides been given to *Ficus Sausureana*, and other species of figs; and is, according to M. Desvaux, applied to *Clusia Galactodendron*.

**COW-WEED.** *Chærophyllum sylvestre*.

**COW-WHEAT.** A common name for *Melampyrum*.

**CRAB.** *Pyrus Malus*. — **QUEENSLAND.** *Petalostigma quadrilocularis*. — **SIBERIAN.** *Pyrus baccata* and *P. prunifolia*.

**CRAB OIL.** The oil obtained from *Carapa guianensis*.

**CRAB'S EYE LICHEN.** *Lecanora pallescens*, which was formerly gathered under this name in the north of England for the dyers. [M. J. B.]

**CRAB'S EYES.** The seeds of *Abrus precatorius*.

**CRAB-WOOD.** The timber of *Carapa guianensis*.

**CRACCA.** The name given to a few slender perennial herbs or small bushes of the pea family, which were at one time

placed in the genus *Tephrosia*, from which they differ in having no cup-shaped disc round the ovary. Six species are enumerated, all of them confined to tropical America. Their leaves are unequally pinnate, with four to twelve pairs of small opposite leaflets mostly elliptical in form, and the flowers (about the size of those of a vetch) are arranged in axillary racemes. The straight narrow pods are thin, smooth, and contain a number of seeds. [A. A. B.]

**CRABEBERRY.** *Empetrum nigrum*. — **PORTUGAL.** *Corema alba*.

**CRAM DES ANGLAIS.** (Fr.) *Cochlearia Armoracia*.

**CRAMBE.** A genus of *Cruciferae*, consisting of several species, of which two are edible, namely, *C. maritima* and *C. tatarica*. The former is our well-known Sea Kale. The latter is the Tatar Kenyer or Tartarian bread of the Hungarians, of which an interesting account is given in *Loudon's Encyclopaedia of Plants*, p. 557; but we are not aware of any attempt having been made to cultivate it in this country, although the plant is stated to have been introduced in 1789.

The Sea Kale, *C. maritima*, is a hardy native perennial, found on various parts of the coast, growing among sand and shingle. It is easily recognised by its broad wavy toothed gray-coloured leaves, which, with the stem, have a peculiar appearance, from being glaucous, or covered with a very fine bloom. The flowers are white and have a strong smell of honey. It appears to have been known to the Romans, who gathered it in its wild state, and preserved it in barrels for use during long voyages. From a remote period it has also been used in this country by residents near the sea, but its introduction into our gardens is comparatively of recent date, although it is recorded that bundles of it were exposed for sale in Chichester market in 1753. It was not known about London until 1767, when Dr. Lettson cultivated it at Camberwell, and was the first to bring it into general notice. It has now become a common vegetable, and when blanched, the young shoots and leaves, before their complete development, are cut and tied up in small bundles for boiling. When thoroughly dressed they are served like asparagus, and are esteemed exceedingly choice and delicate. [W. B. B.]

**CRANBERRY.** The fruit of *Oxycoccus palustris*, also sometimes applied, according to Lindley, to those of *Vaccinium Vitis idæa*. — **AMERICAN.** *Oxycoccus macrocarpus*. — **TASMANIAN.** *Astroloma humifusum*.

**CRANE'S BILL.** The common name for *Geranium*.

**CRANICHS.** A rather numerous genus of American orchids, mostly tropical, with the habit of *Spiranthes*, but with a dorsal concave not convolute lip. The flowers are insignificant, and the species scarcely more than weeds.

**CRANIOLARIA.** A genus of Pedaliads, distinguished from its congeners by the somewhat bell-shaped calyx, which is cleft or five-toothed, and by the tube of the corolla widening toward the upper part, where it is bell-shaped and two-lipped, the upper lip of two pieces, the lower of three, the middle piece of the latter longer than the other two. The name of the genus was given in allusion to some resemblance which the ripe fruit has to the skull, in Latin 'cranium.' The species are herbaceous, natives of the tropical parts of America, usually very hairy and viscid; the leaves are opposite angled or five-lobed, the flowers from the axils of the leaves or terminal, the corolla being generally pale, with the throat variegated. The genus was originally formed to comprehend a plant known as the *Martynia Craniolaria*, first introduced in 1733, and which is now *Craniolaria annua*: a handsome greenhouse plant, easily cultivated, attaining a height of two feet, with leaves somewhat heart-shaped, five-lobed and toothed, the tube of the corolla longer than the calyx, which has at the base two leaflets or bracts. Dr. Lindley states 'that its fleshy and sweet root is preserved in sugar by the Creoles as a delicacy. In the dry state it is said to be a bitter cooling medicine.' Another species is the *C. unibracteata*, which is perennial; the tube of the corolla is as long as the calyx, which has one bract. The flowers are in clusters, sulphur yellow, with purple dots. [G. D.]

**CRANIOSPERMUM.** A small genus of Siberian herbs belonging to *Boraginaceae*. They are hairy with obovate or linear leaves, and rather small rose-coloured flowers with a five-parted calyx, a tubular corolla, five-cleft at the mouth, the segments erect, the throat without scales; stigma capitate; nuts four, obliquely depressed at the apex, affixed to a four-sided pyramidal central column, the disk sub-concave with a narrow margin. [J. T. S.]

**CRANSON.** (Fr.) *Cochlearia officinalis*.  
— **RUSTIQUE.** *Cochlearia Armoracia*.

**CRAPAUDINE.** (Fr.) Any *Sideritis*.

**CRAQUELIN.** (Fr.) *Fragaria collina*.

**CRASPEDARIA.** A name given by Link and others to various polypodaceous ferns, now referred to the genera *Gonophlebium*, *Nipholobus*, &c. [T. M.]

**CRASS.** Something thicker than usual. Leaves are generally papery in texture; the leaves of cotyledons, which are much more fleshy, have been called crass.

**CRASSULACEÆ.** (*Sempervivum*, *Succulentæ*, *House-leeks*, *Stonecrop* family.) A natural order of polypetalous calyciflorous dicotyledons, included in Lindley's violal alliance. Succulent herbs or shrubs with exstipulate (no stipules) leaves, and clustered flowers, which are often turned towards one side; sepals three to twenty, more or less combined; petals three to twenty, separate or united; stamens equal

in number to the petals or twice as many; ovary composed of numerous one-celled carpels, having scales at their base; fruit consisting of follicles. Natives of dry places in all parts of the world. They are found on naked rocks, old walls, or hot sandy plains, alternately exposed to the heaviest dews of night, and the fiercest rays of the noon-day sun. Acridity prevails in many plants of this order. Some species are cooling in their properties, others are astringent. *Sedum acre* is very acrid, and is hence called Wall-pepper; it is abundant on sandy shores. *Sempervivum tectorum*, the Houseleek, is so called from being grown on the tops of houses. *Bryophyllum calycinum* has the property of producing leaf-buds along the margin of its leaves. There are about 470 species, distributed among twenty-four genera, of which *Crassula*, *Bryophyllum*, *Sedum*, *Sempervivum*, and *Penthorum* are examples. [J. H. B.]

**CRASSULA.** A well-known genus giving its name to the order *Crassulaceæ*. It consists of herbs or shrubs, with, for the most part, more or less fleshy leaves and stems, and white or pink flowers in loose cymes or compact heads. The form and disposition of the leaves vary in the different species; frequently the two opposite leaves are conjoined at the base, as in *C. perfoliata*.

*Crassula perfoliata* (stem and leaves).

The sepals are five, shorter than the five petals; the stamens are five, perigynous; there are also five hypogynous scales; the ovaries are five, distinct one from the other, and ripening into as many few or many-seeded follicles. About 120 species are known, the majority peculiar to S. Africa, with 3 in Tropical Africa, and a few in the Mediterranean region. Numerous species are in cultivation. Some of them frequently produce little leaf-buds in place of flowers on their inflorescence. [M. T. M.]

**CRATÆGUS.** A well-known genus of moderate-sized trees, commonly called thorns, belonging to the sub-order *Pomaceæ*, of rosaceous plants, closely allied to the medlar, *Mespilus*, from which it is distinguished by the small (not leaf-like) segments of the calyx, and by the different form of the fruit. The thorns are natives of Europe, North America, and the temperate regions of Asia and Africa, bearing for the most part a great resemblance to one another in habit of growth, and agree-

ing generally in having cut leaves, white fragrant flowers, and scarlet berries, though there are exceptions to all these characters. All are hardy and ripen their fruit in the climate of Great Britain, and being very ornamental, both when in flower and fruit, are highly prized by the landscape gardener. *C. Oxyacantha*, the Hawthorn, is to be met with on a dry soil in most parts of Europe, in the North of Africa, and in Western Asia, varying greatly in size according to soil and climate, and presenting in the shape, size, and surface of its leaves, and in the colour of its berries, numberless shades of difference. The leaves vary also in their amount of pubescence; and the flowers, though generally white and fragrant, sometimes have an unpleasant fishy smell; they are either tinged with red, or, in some cultivated varieties, are of a full pink or crimson. The fruit or 'haw,' too, varies greatly in size, shape, and colour, being sometimes oblong, sometimes nearly globular, sometimes downy, at other times smooth and polished. Varieties have been observed in which it changes its usual crimson hue for black, orange, golden-yellow, or white. In some districts, each haw contains a single nut, in others they more frequently contain two. In spite, however, of all these liabilities to variation, a hawthorn tree can be distinguished at any season of the year without recourse being had to botanical characters; and a mere cursory examination of almost any other species of crataegus will suffice to assign it to its proper genus. Most of the cultivated species blossom in the month which has given to the Common Hawthorn the name of May-tree; but no one of them is more worthy of the title than that which has so long held it. Collections of thorns exist in various places in Europe, some containing from fifty to eighty sorts, including varieties; for a full account of which the reader should consult *Loudon's Arboretum Britannicum*. French, *Aubépine*; German, *Hagedorn*. The hawthorn is the badge of the Ogilvies. [O. A. J.]

**CRATERA.** The cup-shaped receptacle of certain fungals.

**CRATERIFORM.** Concave, hemispherical, a little contracted at the base.

**CRATÆVA.** A genus of the caper family consisting of shrubs or trees, natives of tropical regions, whose flowers have a four-parted calyx, a corolla of four stalked petals inserted on the margin of a hemispherical fleshy receptacle, and eight to twenty stamens inserted with the petals; ovary on a long stalk; stigma sessile; berry globular, one or two-celled, containing pulpy matter, in which the seeds are imbedded. *C. Nurvala*, a native of Malabar and the Society Isles, is a sacred tree in the latter islands, and is planted in graveyards. Its leaves are aromatic, bitter, and stomachic, and other parts of the tree are likewise used medicinally. The bark of the root of *C. gynandra*, the Garlic Pear, blisters like

cantharides. Some of the species have a strong smell of garlic. [M. T. M.]

**CRATOXYLON.** A genus of opposite-leaved bushes or small trees of the St. John's wort family, found in the Malayan peninsula, China, Java, and the adjacent islands. Its chief distinguishing characters are the winged seeds, contained in a three-celled capsule, which when ripe is surrounded by the withered calyx. The leaves are stalked, or sessile and entire, generally lance-shaped or elliptical in form, but sometimes oboval. The flowers are white, chocolate, or rose-coloured, arranged in terminal panicles, or arising from the axils of the leaves. They have a five-leaved calyx, five roundish petals, and three or five parcels of stamens surrounding an ovary crowned with three styles. About ten species are known. *C. Hornschuchii*, a Javanese species, is said to be slightly astringent and diuretic. [A. A. B.]

**CRAWFURDIA.** A genus of Nepalese gentianaceous herbs with twining stems and large axillary flowers. They have a bell-shaped corolla whose limb is five-cleft, or ten-cleft, with five of the divisions smaller than the rest; filaments of the five stamens dilated; ovary one-celled, style straight; stigma two-cleft with oblong recurved lobes; disc hypogynous, five-lobed; capsule stalked, one-celled, many-seeded. [M. T. M.]

**CREAM-COLOUR.** White, verging to yellow, with little lustre.

**CREAM FRUIT.** *Rouppellia grata*.

**CREAM OF TARTAR TREE.** *Adansonia Gregorii*.

**CREEPER, TRUMPET.** An American name for *Tecoma radicans*.

**CREMANIUM.** A genus of tropical American shrubs or small trees belonging to *Melastomaceæ*. They have terminal panicles of small white flowers with the parts in fours or fives; the stamens twice as many as the petals; the berry globose, depressed at the apex, blue or violet, adhering to the circumscissile calyx, with three to five cells, and numerous seeds. *C. reclinatum* and *tinctorium* yield a yellow dye. [J. T. B.]

**CREMASTRA.** A little-known genus of terrestrial orchids from India and Japan, with broad ribbed leaves, and radical scapes bearing each a spike of dull-red tubular flowers. Two species are known. *Hyacinth-orchis* of Blume is the same genus.

**CRÈME D'ABSINTHE.** A bitter aromatic liqueur prepared from *Artemisia Mutellina* and *A. spicata*.

**CREMOCARP.** Such fruits as that of umbellifers, consisting of two or more indehiscent inferior one-seeded carpels adhering round a distinct and separable axis.

**CREMOLOBUS.** A genus of *Crucifera* from Peru and Chili, consisting of herbs or

undershrubs, with oblong or ovate leaves, and elongated racemes of numerous yellow flowers; filaments not toothed; pouch stalked, laterally compressed, constricted at the partition as in *Biscutella*, with orbicular valves winged on the back, tipped by the persistent style; seed solitary in each valve. [J. T. S.]

**CREMOSTACHYS.** M. Tulasne's name for a genus of *Aphorbiaceae*, which proves to be the same as *Bennettia*. See GALLARIA.

**CRENA, CRENATURE, CRENEL.** A round or convex flat tooth.

**CRENATE, CRENELLED.** Having convex flat teeth. When these teeth are themselves crenated, bicrenate is the term which is used.

**CRENATO-DENTATE.** Divided at the edge into triangular notches.

**CRENATO-SERRATE.** When serratures are convex, and not straight.

**CRENULATE.** Having the edge divided into small crenela.

**CRE'ON.** (Fr.) *Pinus Pumilio*.

**CREPIS.** A genus of herbaceous plants, known as Hawk's-heads, belonging to the chicory tribe of compound flowers, and distinguished among its congeners by the soft whitish deciduous pappus which crowns the cylindrical achenes, which are destitute of a beak, or furnished with but a very short one. The species are common hedge plants throughout Europe, and are uninteresting. [*C. virens* is a common British and European species, extending to the Canaries. It is a very variable plant, the lower leaves being usually toothed mucronate or lyrate, the upper linear sagittate; the stems are much branched, and the flowers are in small yellow heads. It is abundant in waste and cultivated ground, on cottage roofs, &c., flowering throughout the summer.] *C. paludosa* is a much larger plant, not uncommon in moist woods, where it grows to the height of six feet or more. [C. A. J.]

**CRESCENTI-PINNATISECT.** When the lobes of a pinnated leaf become gradually larger as they approach the end.

**CRESCENTIA.** The typical genus of *Crescentiaceae*. Its four species are inhabitants of the forests of tropical America, and are either small trees or large shrubs, having simple or trifoliate leaves arranged alternately or in clusters upon the stem. The flowers are produced upon the stem or old branches, and are distinguished by having a two-lipped calyx, with the lips undivided; the corolla being somewhat bell-shaped, and having a long tube puffed out on one side. Their fruits have a hard woody shell or rind, and contain numerous seeds nestling in pulp. *C. alata* is a native of Western Mexico, growing mostly in the vicinity of the sea-coast; but it is cultivated in the Philippine and Ladrones or Marianne Islands. It is called Teconate in Mexico, and forms a tree about thirty

feet high, with its leaves growing in clusters of three; the two outer ones being undivided and stalkless, while the central one is composed of three distinct leaflets, with a long winged stalk, and is compared to a cross by the inhabitants of the Philippines, the tree being called *Hoja-cruz*, and a decoction of its leaves used as a remedy against spitting of blood. The fruit is about the size and of the same colour as an orange, and contains a sourish-bitter pulp, which the Mexicans boil with sugar and administer internally as a cure for chest complaints; while the shells are converted into drinking cups.

*C. cucurbitina*, the Calabazo de playa of the Panamians, is a shrub about twelve or fifteen feet high, found growing very commonly on the coasts of Central America, the West Indian, and some of the Pacific Islands, and cultivated in Java. Its leaves are placed singly and alternately upon the stem, and vary very much in shape. Its fruit is either round, egg-shaped, or elliptical, and has a very brittle shell. This shrub has been reported to possess poisonous properties, but as the rest of the plants belonging to the order are of a harmless character, probably some mistake has occurred.

*C. Cujete*, commonly called the Calabash-tree, from the Spanish word Calabazo, which means a gourd or pumpkin, and alludes to the resemblance of the fruits, is a tree about thirty feet high, and is found growing either wild or cultivated in various parts of tropical America, and the West Indies. Its flowers are variegated with green, purple, red and yellow; and its leaves are stranged in clusters of five, all of them undivided, and of a narrowly elliptic form, the upper half being broader and terminated by a short point, while the lower tapers gradually to the base. The fruits are generally of a globular form, or sometimes slightly oval, and have a very hard woody shell, which is made to serve many useful purposes in the domestic economy of the inhabitants of the above-mentioned countries—basins, cups, spoons, water-bottles, pails, and even kettles being made of them; the latter, it is said, standing the fire several successive times before they are destroyed. In fact they in great measure take the place of pottery-ware, and many of them are carved and polished or stained in various quaint devices. The pulp is esteemed as a medicine, acting as a purgative, and considered to be beneficial in diseases of the chest; it is also roasted and used as a poultice for bruises and inflammations. The wood of the Calabash-tree is light, tough, and pliant, but is only obtainable in planks six or eight inches broad. [A. S.]

**CRESCENTIACEÆ.** (*Crescentiaceae*.) A small family of corollifloral dictyodendons, closely allied to *Stemoniaceae*, and often associated with them as a tribe or suborder, but differing in their one-celled ovaries with parietal placentas, and in their large succulent fruits, with almond-like wingless

seeds. They are usually trees with alternate or rarely opposite leaves, and rather large flowers growing out of the old stems or branches. Calyx at first undivided, but at length splitting into irregular pieces. Corolla gamopetalous, irregular, somewhat two-lipped; stamens four, inserted in the corolla, two long and two short, often with the rudiment of a fifth; ovary free, one-celled, with two or four parietal placentas; ovules numerous. Fruit woody, not splitting, and containing large seeds immersed in pulp; embryo without albumen. They are tropical and subtropical plants, extending from 30° S. to 30° N.; they abound in Madagascar, the Mauritius, the Seychelles, and other islands of Eastern Africa. In America they are represented by ten species, in Asia by two only, and they are not found in Europe, nor on the continent of Australia. Some, as *Figelia pinnata*, yield timber, which is used for canoes and for pillars. *Crescentia Cujete* is the Calabash tree, whose gourd-like fruits have been seen two feet in diameter in the west of Africa. A large Calabash can support two men in crossing a river. *Parmentiera cerifera* yields wax, and is called the Candle tree in Panama. The fruit of *P. edulis* is the Quahuixtli of Mexico, and is edible. The fruit of *Tanacetum ilacinum* and of *Colea Telfairia* is eaten. There are eleven known genera and thirty-four species. Illustrative genera:—*Crescentia*, *Parmentiera*, *Colea*, *Figelia*, and *Tanacetum*. [J. H. B.]

CRESS, AMERICAN. *Barbarea praecox*. —, AMERICAN WATER. *Cardamine rotundifolia*. —, AUSTRALIAN. The Golden Cress, a broad yellowish-leaved variety of *Lepidium sativum*. —, BASTARD. The common name for *Thlaspi*. —, BELLEISLE. *Barbarea praecox*. —, BITTER. A common name for *Cardamine*. —, GARDEN. *Lepidium sativum*. —, GOLDEN. A variety of *Lepidium sativum*. —, INDIAN. *Tropaeolum majus*; the name of Indian Cresses is also given to the order *Tropaeolaceae*. —, LAND. *Barbarea praecox*. —, MEADOW. *Cardamine pratensis*. —, MOUSE-EAR. *Arabis Thaliana*. —, PARA'. *Spilanthes oleracea*. —, PENNY. *Thlaspi arvense*. —, PETER'S. An old name for *Crithmum maritimum*. —, ROCK. A common name for *Arabis*; also an old name for *Crithmum maritimum*. —, SPANISH. *Lepidium Cardamines*. —, SPRING. *Cardamine rhomboidea*. —, SWINE'S. *Senebiera Coronopus*. —, THALE. *Arabis Thaliana*. —, TOOTH. A common name for *Dentaria*. —, TOWER. *Arabis Turrita*. —, VIOLET. *Ionopsidium acaule*. —, WALL. *Arabis Thaliana*; also a common name for *Arabis*. —, WART. *Senebiera Coronopus*; also a common name for *Senebiera*. —, WATER. *Nasturtium officinale*. —, WINTER. *Barbarea vulgaris*; also a common name for *Barbarea*. —, YELLOW. *Nasturtium palustre*, and *N. amphibium*; also *Barbarea*.

CRESSA. A genus of *Convolvulaceae*, containing probably a single species, though very variable from the different conditions under which the plant grows, as it is a

common sublittoral undershrub in tropical and sub-tropical regions all over the world. It has scattered entire leaves, and crowded flowers in the axils of the uppermost leaves. The calyx consists of four sepals; the corolla is funnel-shaped and five-cleft; the ovary is two-celled with two ovules in each cell; the capsule contains from one to four seeds. [W. C.]

CRESSON ALE'NOIS. (Fr.) *Lepidium sativum*. — AMER. *Cardamine amara*. — D'EAU or DE FONTAINE. *Nasturtium officinale*. — DE PARA'. *Spilanthes oleracea*. — DES JARDINS. *Lepidium sativum*. — DES PRE'S. *Cardamine pratensis*. — DU BRE'SIL. *Spilanthes fusca*. — DU PE'ROU. *Tropaeolum majus*. — DE ROCHE. *Chrysosplenium*; also *Cardamine petraea*.

CRESS-ROCKET. *Vella Pseudo-cytisus*.

CRESTED. Having an elevated, irregular or notched ridge, resembling the crest of a helmet. This term is chiefly applied to seeds, and to the appendages of anthers; it also belongs to bracts which form with their edges an appearance like that of a crest, as in *Melampyrum*.

CRETACEOUS. Very dull white, with a little touch of grey; chalky.

CRETE DE COQ. (Fr.) *Celosia cristata*; also *Erythrina Crista galli*; also *Rhinanthus major*. — MARINE. *Crithmum maritimum*.

CRETELLE COMMUNE. (Fr.) *Cynosurus cristatus*.

CREVE-CHIEN. (Fr.) *Solanum nigrum*.

CREYAT. The Indian name for *Justicia paniculata*.

CRIBRARIA. One of the most elegant genera of myxogastrous Fungi. The lower half of the spore-case or peridium is permanent, but the upper half partially shells off, and leaves behind a complicated network. The species are confined to the northern temperate regions. Two species have been found in this country. [M. J. B.]

CRIBROSE. Pierced (like a sieve) with numerous close small apertures.

CRINITE. Having tufts of long weak hairs, growing from different parts of the surface.

CRINODENDRON. The name of a small Chilean tree of the lime-tree family, having opposite or alternate shortly-stalked and smooth leaves, with their margins toothed near the points. The flower-stalks, which are single from the axils of the leaves, and longer than them, are thickened towards the apex, and bear a rose-coloured flower, which has a two-lobed five-toothed calyx; five pyramidal fleshy petals hollowed at their base; about twelve stamens with anthers as long as their stalks, and a globular ovary crowned with a single style. The fruit is a four or five-celled capsule about the size of a cherry, and containing numer-

ous seeds. Chequehue is the name given by the Chilians to this plant, which is known to botanists as *Crisodendron Hookeri* or *C. Palagua*. [A. A. B.]

**CRINUM.** A genus of remarkably handsome amaryllidaceous plants, well-known in gardens. They are tropical or sub-tropical herbs, generally of large size, with columnar or spherical bulbs, lorate-lanceolate leaves, and a solid scape bearing a many-flowered umbel. The perianth has a long slender tube scarcely enlarged at the mouth, and a six-parted limb of nearly equal segments, which are erect, spreading or reflexed. The six stamens are inserted in the mouth of the tube. The ovary is three-celled, containing many ovules; the style filiform and inclined, and the stigma obtuse or obsoletely three-lobed. There are numerous species of Asiatic, Australasian, and South American origin, while one or two are met with in Western Africa, and some of a hardier character in South Africa. Many very fine cross-bred varieties have also been obtained in gardens. One of the best known species is *C. amabile*, which Dr. Herbert regards as a spontaneous cross, probably between *C. procerum* and *C. seylanicum*, also stating that it is cultivated for its beauty in Sumatra. This plant has thick pyramidal bulbs, and sheathing strap-lance-shaped erect leaves, three to six feet long and three to six inches wide in the centre. The scape is much compressed, three to four feet high, and bears an umbel of from twenty to thirty large rosy fragrant flowers, having a tube five or six inches long, and a limb of lanceolate-linear lobes as long as the tube, and pale flesh-coloured within. The South African *C. capense*, is sufficiently hardy to grow in a protected border out of doors in warm situations. This has roundish ovate bulbs, and lanceolate-linear glaucous leaves, two to three feet long, ending in long narrow points; the flowers are pleasantly scented, flesh-coloured, and about six inches long. It is sometimes called *C. longifolia*. Among the interesting hybrids is one called *C. Mitchumii*, raised between *australe* and *capense*; this is a very handsome plant, perfectly hardy in favourable positions, and produces a succession of flower-scapes till the winter. Another is *C. Herbertii*, raised between *scabrum* and *capense*, a plant of great beauty, bearing about a dozen flowers on a scape three feet high; the tube is four inches long, and the limb three and a half inches, while the colour is bluish with deep-red stripes. See Plate 2, fig. 4. [T. M.]

**CRISPATE** (ad). **CRISPUS.** When the edge is excessively and irregularly divided and puckered; also when the surface is much puckered and crumpled. Good examples are afforded by 'curled' endive, 'curled' kale, and the like. Also a diminutive of *Buliate*.

**CRISTALLINE.** (Fr.) *Meembryanthemum crystallinum*.

**CRISTATE.** The same as *Crested*.

**CRISTATO-RUGOSE.** When the wrinkles of a surface are deep and sharp-edged.

**CRISTE MARINE.** (Fr.) *Crithmum maritimum*.

**CRITHMUM.** The Samphire, an umbelliferous plant, easily distinguished from all others of the same order by its glaucous twice-ternate leaves, the divisions of which are very succulent and taper towards either extremity. The flowers are greenish-yellow and inconspicuous, except from the contrast between their general hue and the blue tinge of the foliage. The whole plant is 'of a spicily taste with a certain saltiness,' on which account it has been long held in great repute as an ingredient in salads, and was declared by Gerard to be 'the pleasantest sauce, most familiar, and best agreeing with man's bodie for digestion of meates.' For this purpose it is now nearly gone out of use, but it is still so much valued as a pickle that other succulent marine herbs are not unfrequently offered for sale under the name of Samphire, for example *Salicornia* and *Suaeda*. All these substitutes, which are worthless for the purpose of pickling, may be infallibly detected on a simple examination of the leaf. Samphire is exclusively confined to the rocky sea-shore, and, like many other marine plants, has an extensive geographical range, being found on most of the shores of Europe, from the Crimea to the Land's End, and extends even to the Canaries. The best pickled Samphire is made from leaves which have been gathered in May, before the appearance of the flower-stalk; otherwise it is apt to be tough and stringy. The etymology of the name *Samphire* is somewhat curious; it was formerly written *Samplier*, a corruption of *Saint Pierre*; and, more anciently still, it was called by the French *Perce-pierre*; by the Italians, *Herba di San Pietro*, and in Latin, *Petræ crescentius*. Thus a herb properly enough called Rock-cress from its growing in the crevices of rocks, came to be known as Peter's cress (the name Peter meaning a rock). The change to *Saint Peter's Herb* was an easy one; the postfix 'herb' being dropped, *San Pietro* became *Samplier* and that *Samphire*. French, *Bacille*; German, *Meerfenchel*. [C. A. J.]

**CRITHO.** A genus of grasses belonging to the tribe *Hordeæ*, not considered by modern authors to be distinct from *Hordeum*, under which it is described by Steudel. The only species is the curious Nepal Barley, *C. egiceras*, which is cultivated at great elevations on the Himalayas and Thibet. The grain has been frequently sent to Europe from those countries, recommended as a very hardy kind, arriving at maturity within an unusually short period after sowing. It has not, however, been found of much value in Britain, where it is chiefly cultivated in botanical gardens. [D. M.]

**CRITHOPSIS.** A genus of grasses be-

longing to the tribe *Hordeae*, scarcely distinct from *Elymus*. One species is described, namely, *C. rachitrichus*, a native of Syria and Persia. [D. M.]

**CROCEOUS, CROCATUS.** Saffron-coloured.

**CROCOSMIA.** A beautiful genus of *Iridaceae*, separated from *Tritonia*, and consisting of one species, *C. aurea*, a native of South Africa. It is a perennial Ixia-like herb, with fleshy corms, slender erect compressed stems terminating in a branched flower-spike, the leaves narrowly sword-shaped, and the flowers, sessile on the branches, large, deep orange-coloured, and not inapily compared to large crocus blossoms. The perianth has a longish curved slender tube, and a nearly regular six-parted limb of oblong segments spreading in a star-like form, which causes the long filaments and style, which are fully as long as the segments, to stand out very prominently. The ovary is oblong with about ten or twelve ovules in each of its three cells; this grows into a three-lobed subglobose capsule, having about three seeds in each cell. In this particular, and in not having the throat of the perianth enlarged, this plant differs from *Tritonia*, with which it had been associated. [T. M.]

**CROCUS.** A well-known genus of *Iridaceae*, very much prized in gardens as affording some of the earliest of spring flowers. The species and varieties are numerous, and exceedingly beautiful, best known as early spring bloomers, a large proportion of them flowering at that season; but also including several which are very handsome autumn-flowering kinds. They are all dwarf herbs, with fleshy corms and grassy leaves, the latter not fully developed till after the flowers have faded. The perianth is funnel-shaped with an elongated tube, and a six-parted limb of concave petaloid segments, of which the inner are rather smaller than the outer series: these segments are erect and closed in cloudy weather and at night, but expand under the influence of sunshine. There are three erect included stamens inserted in the throat of the tube, and an elongated style terminated by three dilated wedge-shaped fleshy cleft or fimbriated stigmas. The ovary is three-celled, containing numerous seeds. The species are mostly found in the southern and eastern parts of Europe, and in Asia Minor. A few species extend to central Europe, and one or two, long cultivated for ornamental purposes, have become established in some localities in England. *C. vernus*, one of these latter, is a handsome plant producing in very early spring its large bluish-purple flowers with orange-coloured stigmas. Another of them is *C. pyreneus* or *audiflorus*, an autumnal-blooming species, producing light purple flowers. *C. vernus* and *versicolor* have yielded many of the fine garden spring-flowering sorts, other favourite ones blooming at that early season being, *C. imperatorius*, *viridatus*, *reticulatus*, *annulatus*, *lageneflorus*, with its variety *luteus*. Of the autumnal-

blooming species some of the most beautiful are *C. speciosus*, *pulchellus*, *Visticus*, *Cartwrightianus*, *cancellatus*, *medius*, *Boryanus*, *bysantinus*, and *odoratus*. *C. sativus*, which is a light-purple autumnal-flowering species, formerly cultivated about Saffron Walden, and partially naturalised, yields the saffron of the shops, which consists of the deep orange-coloured stigmas of the flowers gathered with part of the style, and carefully dried. According to Dr. Pereira, a grain of good commercial saffron contains the stigmas and styles of nine flowers, and consequently 4,320 flowers are required to yield one ounce of saffron. English grown saffron is now rarely, if ever, met with in commerce. The best comes from Spain, while that imported from France is usually considered of second-rate quality. The quantity imported varies between 5,000 and 20,000 lbs. weight per annum. Saffron has a bitter taste, and a penetrating aromatic odour, and was formerly considered to possess stimulant, emmenagogue, cordial, and antispasmodic properties, but when administered in large quantities it is narcotic. It is employed, especially on the continent, as a flavouring and colouring ingredient in culinary preparations, liqueurs, &c., and in modern medicine is only applied for similar purposes, except when included in the domestic pharmacopœia. Saffron gives to water and alcohol three-fourths of its weight of an orange-red extract, which is largely employed in painting and dyeing. Another colouring agent of the same deep orange colour, called safflowers, is quite different from saffron, and consists of the florets of *Carthamus tinctorius*. [T. M.]

**CROISSETTE.** (Fr.) *Gentiana cruciata*. — **VELUE.** *Gallium cruciatum*.

**CROIX DE JÉRUSALEM** or **DE MALTE.** (Fr.) *Lycchnis chalcidensis*. The name *Croix de Malte* is also applied to *Tribulus terrestris*. — **DE ST. JACQUES.** *Sprekelia formosissima*.

**CROSSANDRA.** A genus of Indian *Acanthaceae*, consisting of shrubs or herbs with subentire verticillate leaves, and large red flowers in terminal four-cornered spikes, with broad bracts, and narrow membranaceous bracteoles. The calyx is five-parted, with broad lobes, the inner ones being smallest; the corolla has a long tube, and a flat five-cleft limb; the four didynamous stamens are included in the tube; the one-celled anthers are hairy and ciliated at the margin; the capsule is compressed and two-celled, with four ovate seeds at the base. The genus is nearly related to *Sonchidrium*, which has, however, a more prostrate habit, and more slender anthers. [W. C.]

The same name is given to a little known genus of terrestrial orchids, near *Gastrodia*.

**CROSSOSTEMA.** A climbing shrub of the passion-flower family, found in Sierra Leone. The calyx and corolla each consist of five segments; those of the corolla are larger than the sepals, more deeply

coloured, and three to five-nerved; within them is a 'crown' consisting of one row of filaments. The ovary is placed on a short stalk which is expanded into a disc-like mass, with five short acute teeth at the margin, alternating with the five stamens which arise from the same place; it is terminated by a slender style with a dilated stigma, and is internally one-celled with several ovules attached to the walls of the ovary. [M. T. M.]

**CROSSOSTYLIS.** A genus of trees placed by Lindley and others among *Lecythidaceae*, but by Bentham referred to *Rhinophoraceae*. The trees are natives of the Society and Feejee Islands. They have opposite entire leaves; flower-stalks arranged somewhat umbel fashion, jointed in the middle; flowers greenish with four or five segments to the calyx, and as many shortly-stalked petals; stamens about twenty on a short disc alternating with an equal number of sterile stamens; ovary superior, with five to twelve compartments, in each of which are two ovules; fruit fleshy, but ultimately opening by two valves. [M. T. M.]

**CROSSOTOMA.** The name of an Australian shrub, of the order *Goodeniaceae*, separated by Don from *Scævola*, but by others ranked with the latter, from which it differs in the calyx being imperfectly developed or obsolete, and in the segments of the corolla being fringed. [M. T. M.]

**CROSS-SPINE.** *Stauracanthus aphyllus*.

**CROSSWORD.** The common name for *Crucianella*; also applied to *Galium* or *Vaillantia cruciata*, and to *Eupatorium perfoliatum*. It is further sometimes applied to the cruciferous family.

**CROTALARIA.** A very extensive genus of papilionaceous leguminous plants, containing between 250 and 300 species, natives of the tropics and sub-tropics of both hemispheres. They are either herbs or small shrubs, some having simple and others compound leaves. Their flowers are produced in racemes, either opposite the leaves or at the ends of the branches, and are usually of a yellow colour. They have a somewhat two-lipped calyx; a papilionaceous corolla, the upper petal or standard being heart-shaped, and the lower or keel sickle-shaped; and the stamens united into a column which is split down one side. The legume or pod is curved inwards, and of an oblong form, with its sides puffed or swollen out.

*C. Burha* is a small shrub with numerous spreading stiff branches, slightly armed with spines, growing in arid sandy places in Sindh. Its leaves are of an oblong form and wide apart on the branches; and the whole plant is covered with silky hairs. The tough twiggly branches are used in Sindh for twisting into tough ropes.

*C. Espadilla*, a harsh shrubby plant about a foot high, growing in sandy places in Venezuela, has bluntly lance-shaped leaves, covered with stiff, close-pressed, shining

hairs, and when young of a fine golden colour. This plant is a common domestic medicine in Venezuela; a decoction of it is a sudorific, and it is used in fevers.

*C. juncea*, the Sunn-hemp of India, is a shrubby plant growing from eight to twelve feet high, with a branching stem marked with longitudinal furrows; when cultivated, however, it is sown close, so as to prevent branching as much as possible. Its leaves are on short stalks, and are either bluntly lance-shaped, or very narrow and sharp-pointed, from two to six inches long, thickly covered with shining silky white hairs, which give them a silvery appearance. The flowers are of a beautiful bright-yellow colour, resembling those of the common broom; they are produced in long racemes at the ends of the branches, and are succeeded by club-shaped stalkless pods about two inches long, containing numerous kidney-shaped seeds. This plant is extensively cultivated in different parts of Southern Asia, particularly in India, on account of the valuable fibre yielded by its inner bark; and which is known by the names of Sunn-hemp, Bomby-hemp, Madras-hemp, Brown-hemp, &c. The stems after being cut are steeped in water for two or three days in order to loosen the bark, they are then taken out in handfuls and bent so as to break the interior wood without injuring the fibre; the operator then beats them upon the surface of the water until the fibrous part is entirely separated, when it is washed and hung upon bamboo poles to dry, and afterwards combed to separate the filaments from each other. The fibre thus obtained is very strong, and is considered to be equal if not superior to some kinds of Russian hemp: it is employed for cordage, canvas, and all the ordinary purposes of hemp. A variety produced at Jubbulpore in Malwah, and called Jubbulpore-hemp, has been supposed to be the produce of a different species, *C. tenuifolia*, but that species is now united with the present. Besides its use as a fibrous plant, it is grown in the Madras territories as a food for milch cows, and is said to be very nourishing.

*C. retusa*, a native of the East Indies, but naturalised in the West Indies and Brazil, is an annual plant with smooth branching stems, from four to six feet high, and oblong wedge-shaped leaves notched at the top, smooth upon the upper surface, but covered with short silky hairs underneath. This is cultivated for its fibre in the Madras territory. [A. S.]

**CROTON.** An important genus of *Euphorbiaceae*, among which it may be known by the flowers being monœcious, with a five-parted calyx. The male flowers have five petals, and ten stamens, and the female flowers are destitute of petals, but have three styles, divided into two or more branches. The fruit consists of three carpels separating one from the other, and each containing one seed. The species are numerous and vary very much in general

appearance, some being herbs, others trees, and some having entire, others divided leaves.

*C. Tiglium* is the most important tree of this genus in a medicinal point of view, as it produces the seeds whence croton oil is extracted. The tree is a native of Coromandel, the Indian Archipelago, &c., and has oblong-pointed leaves covered with stellate hairs, when young. One seed is sufficient to act as a purgative, but the oil expressed from the seeds is yet more powerful, though sometimes uncertain in its action: one drop is usually sufficient, hence the great value of this drug in cases where smallness of dose, speediness of action, and powerful effects are required, as in mania, apoplexy, dropsy, &c. It is so acrid that it is exhibited usually in

*Croton Tiglium.*

pills in order to avoid the burning heat it occasions in the throat if swallowed by itself: on this account it is not used in any case where there is inflammation of the bowels. In large doses it acts as a frightful poison, producing symptoms like those of cholera. Externally it has been used as a counter-irritant. It is obtained by submitting the seeds to pressure, an operation which affects the men engaged in it with irritation of the eyes, and air passages, and purging. Dr. Pereira gives the case of a workman who suffered very severely from inhaling the dust of the seeds, he having been occupied for some time in emptying packages of them. The seeds of *C. Pavana* and *C. polyandrum*, Indian shrubs, are also used as purgatives.

Many of the species have aromatic properties. Of these the most important are *C. Eleutheria*, the tree yielding Cascarilla bark, which is chiefly collected on the island of Eleuthera, one of the Bahamas. This bark is esteemed in this country as an aromatic bitter tonic, without astringency, in cases of simple indigestion. It has a fragrant smell when burnt, on which account it is said to have been at one time mixed with tobacco for smoking. *C. pseudo-China*, called in Mexico Ocopalche, yields a

bark having similar properties with the above, and which is used in Mexico in place of cinchona. *C. balsamiferum*, a West Indian shrub, furnishes a spirituous liquor called Eau de Mantes, which is used in irregular menstruation; whilst others are employed in the West Indies, the Cape, &c., for their aromatic, fragrant, and balsamic qualities. *C. lacciferum* in Ceylon, and *C. Draco* in Mexico, yield resin used for varnish-making, &c. The plants known in cultivation as *C. pictum*, &c., are referred to *Codiaeum*. [M. T. M.]

**CROTONOPSIS.** A North American herb of the euphorbiaceous family, scattered over with bran-like scales; the fruit and calyx with stellate hairs. The flowers are monœcious, the males having a five-parted calyx, with five petals, and as many stamens; the females likewise have a five-parted calyx, two of the segments of which are frequently suppressed, with five petaloid scales opposite the sepals; the ovary has three two-lobed stigmas. The fruit is one-seeded. [M. T. M.]

**CROTTLES.** A name given by the lichen gatherers in Scotland to various species, which they distinguish under the names black, brown, dark, light, white, stone crotties, &c. In Scotland the name is applied indifferently, but the merchants and dyers distinguish all the species with an erect or pendulous habit by the name of weeds, while the flat imbricated species, as *Parmelia saxatilis*, are called mosses. The word Crottles is not confined to Scotland, but is used in some parts of England. [M. J. B.]

**CROWBERRY.** *Empetrum nigrum*. —, **BROOM.** An American name for *Corema*.

**CROWEA.** Pretty greenhouse shrubs with simple dotted leaves, and purple flowers, constituting a genus of *Rutaceæ*, and natives of New Holland. The whorls of the flower are in fives; there are ten stamens with hairy filaments, five of which, opposite the petals, are shorter than the remainder; the anthers have an awl-shaped hairy appendage prolonged from the summit; the carpels are five on a five-lobed disc, with five styles fused into one. The fruit consists of five dry segments, which burst into two pieces, each containing one seed. [M. T. M.]

**CROWFOOT.** The common name for *Ranunculus*.

**CROW GARLIC.** *Allium vineale*.

**CROWNBEARD.** An American name for *Verbesina*.

**CROWN IMPERIAL.** *Fritillaria Imperialis*.

**CROWNWORTS.** A name given by Lindley to the group *Mallesherbiaceæ*.

**CROWS-FOOT.** *Echinochloa crus-galli*.

**CROWSILK.** A name sometimes given to the *Conifers* and other delicate green-spored *Algae*. [M. J. B.]

**CROZOPHORA.** A genus of *Euphorbiaceae* found in tropical and northern Africa, and extending eastwards as far as India. It consists of annual or perennial low growing plants, having all their parts densely clothed with starry hairs or shield-shaped scales. The stalked leaves have an oval or heart-shaped blade with either entire lobed or curled margins. The minute green flowers are borne on terminal or axillary bracted racemes, the lower portion of which is occupied by the females, the upper by the males. The latter have a calyx of five divisions, five petals and a central column of five to ten stamens, but most commonly eight, these being arranged in two whorls, the outer one of five short stamens, the inner of three longer, and all of them opposite the calyx leaves. The number and disposition of these stamens afford the chief distinguishing character of the genus. The ripe capsule is about the size of a pea, and covered with shield-shaped scales. It contains three seeds.

*C. tinctoria*, which grows wild in the countries bordering the Mediterranean, is cultivated in the South of France for the sake of a dye which is obtained from it. This dye is called Turnsole, and is obtained by grinding the plants, little herbs seldom more than a foot high, to a pulp in a mill, when they yield about half their weight of a dark green coloured juice, which becomes purple by exposure to the air or under the influence of ammonia. It is chiefly exported to Holland, and is prepared for exportation by soaking coarse linen rags or sacking with it, the rags being previously washed clean. After soaking they are allowed to dry, and are exposed to the influence of ammonia by being suspended over heaps of stable manure. They are then packed in sacks, and ready for shipping to Holland. Not much is known of the uses the Dutch put the dye to, but it is supposed to be chiefly employed as a colouring matter for cheese, and perhaps confectionary, wine, &c. This dye has been confounded by some authors with the litmus of our chemists.

[A. A. B.]

**CRUCIANELLA.** A genus of herbaceous plants, called Crosswort and Petty Madder, and belonging to the *Rubiaceae*. The corolla is funnel-shaped with an exceedingly slender tube and narrow inflexed lobes; the seeds are in pairs, linear not crowned with the calyx. They are found in the southern parts of Europe and Asia, and are of humble growth, bearing thin leaves inserted in opposite pairs, and having stipules at their base so arranged as to simulate a whorled form of growth. The species are rarely cultivated except in botanical gardens, with the exception of *C. stylosa*, a native of Persia and the Caucasus: this is a low tufted herb with rose-coloured flowers, which bloom during the greater part of the summer; it is well adapted for rockeries. French, *Croisette*; German, *Kreuzblatt*.

[C. A. J.]

**CRUCIATE, CRUCIFORM.** Having the

form of a cross, with equal arms, as the flowers of radish or wallflower.

**CRUCIBULUM.** A genus of gasteromycetous *Fungi*, belonging to the natural order *Nidulariet*. It is distinguished from *Cyathus* by its peridium being homogeneous and not composed of distinct strata, and by the sporangia being supported by a cord ending above in a globular swelling sunk in a pit of the sporangium, and including an elastic complicated thread. There is but one species which is common all over Europe, and occurs in the north of Africa, and New Zealand. It is especially fond of the old fronds of ferns, but occurs also on sticks, old ropes, and various other vegetable substances. [M. J. B.]

**CRUCIFERÆ.** (*Brassicaceae*, *Cruciferae*, the *Cruciferous* family.) A natural order of thalamifloral dicotyledons, belonging to Lindley's cistal alliance. Herbs with alternate leaves having no stipules, and flowers, usually yellow or white, arranged in racemes or corymba without bracts; sepals four, falling off; petals four, arranged like a cross; stamens six, of which four are long and two short. Fruit, a siliqua or silicle, that is, a long or short pod opening by two valves, with a partition (septum) in the centre; seeds without albumen; embryo with its radicle folded on the cotyledons. The plants of this very natural order were included by Linnaeus in his class *Tetradynamia*. They are generally distributed, but most abundant in cold and temperate regions, especially in Europe. This order has been divided into sub-orders and tribes according to the nature of the fruit or the embryo. Considering the fruit we have these six divisions:—

1. *Siliqueosae*, a siliqua or long pod opening by two valves from below upwards;
2. *Siliculosae latiseptae*, a silicle or short pod opening with two flat or convex valves, the replem (partition) being in the broadest diameter;
3. *Siliculosae angustiseptae*, a silicle with folded or keeled valves, the replem in the narrow diameter;
4. *Nucumentaceae*, a silicle whose valves do not open, one-celled, having no replem;
5. *Septulatae*, valves with transverse partitions on their inside;
6. *Lomentaceae*, a pod dividing transversely into single-seeded portions, the beak sometimes containing one or two seeds, while the true pod is abortive. The nature of the embryo gives origin to five subdivisions, namely:—1. *Pleurorhizae*, the radicle folded on the edge of the cotyledons;
2. *Notorhizae*, the radicle folded on the back of the cotyledons;
3. *Orthoplocae*, the cotyledons folded on the radicle;
4. *Spirolobae*, cotyledons twice-folded;
5. *Diplocobae*, cotyledons thrice-folded. Crucifers are pungent, and occasionally acrid in their properties. None of them are poisonous; many are culinary vegetables. From containing much nitrogen and sulphur in their composition they give out a fetid odour when decaying. Among the common cruciferous garden flowers may be enumerated wallflower, stock, rocket, honesty. *Brassica oleracea*

is the origin of the cabbage, cauliflower, broccoli, savoy and curled kale. *Brassica Rapa* is the origin of the turnip. The Swede or Swedish turnip is by some said to be a variety of *Brassica campestris*, by others a hybrid between *B. Rapa*, the turnip, and *B. Napus*, the wild narrow, rape or coleseed. *Crambe maritima* supplies sea-kale, which is subjected to the process of blanching in order to fit it for the table. Among the pungent plants of the order are *Sinapis nigra*, the black seeds of which supply the best mustard; *S. alba*, or white mustard, which is less pungent; *Lepidium sativum*, common cress; *Nasturtium officinale*, water-cress; *Cochlearia Armoracia*, horse-radish; and *Raphanus sativus*, the radish. *Isatis tinctoria*, woad, yields a blue dye; and *I. indigotica* is used as indigo in China. Many of the species grow on the sea shore, and have been used as fresh vegetables by the crews of ships affected with scurvy. Hence, *Cochlearia officinalis* receives the name of scurvy-grass. Oil is procured from the seeds of many of the plants; thus we have rape oil, and oil of mustard, and camellina oil. After pressing out the oil from rape-seeds the cake is used as food for cattle. There are 206 known genera, and about 1730 species. Illustrative genera:—*Cheiranthus*, *Arabis*, *Linaria*, *Draba*, *Thlaspi*, *Tessdalia*, *Hesperis*, *Erysimum*, *Capsella*, *Isatis*, *Brassica*, *Bunias*, *Seneciera*, and *Schizopetalum*. [J. H. B.]

**CRUICKSHANKIA.** The name of certain Chilean herbs, constituting a genus of *Couchouaceae*. The plants have branching wavy stems, and yellow flowers in terminal heads. Their calyx tube is globular, its limb with four stalked roundish netted segments, having two stipules at the base of each; the corolla is salver-shaped. The fruit is a membranous two-celled and two-valved capsule. The most remarkable feature in the genus is the curious condition of the calyx before mentioned. [M. T. M.]

**CRUSTA.** The upper surface of lichens.

**CRUSTACEOUS.** Hard, thin, and brittle; as the seed-skin of asparagus, and the thallus of many lichens.

**CRUSTOLLE.** (Fr.) *Ruellia*.

**CRYBE rosea** is a small tuberous orchid with grassy leaves, from Guatemala. It has the habit of *Bletia*, but its pollen is that of an *Arethusea*.

**CRYPsis.** A genus of grasses belonging to the tribe *Agrostideae*. The inflorescence is generally between a thyrse and a capitule; spikelets one-flowered; glumes two, compressed and carinate; pales two, lanceolate, the inferior one nerved; stamens two to three; styles two. Thirteen species are described, mostly annuals, and little known in a cultivated state. [D. M.]

**CRYPTA.** The sunken glands or cysts which occur in dotted leaves. The same as *Cyst*.

**CRYPTADENIA.** A genus of *Thymelaceae*, composed of a few heath-like dwarf

bushes, natives of S. Africa. They differ from their allies in their tubular calyx bearing on its inner surface near the apex of the ovary eight anther-like glands. Their minute linear leaves are numerous, opposite and smooth: the pink flowers, single or in pairs at the apex of the twigs, or from the axils of the upper leaves, consist of a coloured tubular calyx with a four-parted border, covered outside with short silky hairs, and bearing on its tube eight stamens, four of which are short and included, the others longer and slightly protruding beyond the mouth of the tube. *C. uniflora* is a slender pretty bush with pink flowers at the ends of the branches, and is sometimes seen in greenhouses. Five species are known. The name of the genus has reference to the eight hidden glands of the calyx tube. [A. A. B.]

**CRYPTANDRA.** A genus of heath-like under-shrubs, belonging to the order *Rhamnaceae*, natives of New Holland. They are erect branching plants, with alternate entire glabrous leaves, and flowers aggregated at the summits of the branches, or sometimes solitary. The coloured calyx has a campanulate occasionally cylindrical tube attached below to the ovary, but free above, and having a five-cleft limb cut into acute segments. The small hooded petals are inserted in the throat of the calyx, and cover the stamens, which have short filaments, and two-celled anthers opening longitudinally. The three-celled ovary is semi-inferior, each cell containing a single erect ovule; the style is simple, with a three-lobed stigma; the capsule is covered with the persistent calyx. There are upwards of seventy species. [W. C.]

**CRYPTANTHUS.** A Brazilian epiphyte belonging to the *Bromeliaceae*. Its leaves are lanceolate, and conceal the flowers; hence the name. The flowers have the arrangement and structure common to the order, with six stamens inserted on a fleshy epigynous disc, three of them moreover are united to the base of the inner petal-like segments of the perianth. The stigmas are three in number, twisted and hairy. [M. T. M.]

**CRYPTARRHENA.** A very singular genus of tiny stemless epiphytal orchids with spikes of minute yellowish flowers, living in the forests of Surinam and Mexico. They have a lip divided into attenuated segments, and a column furnished at the upper extremity with a hood, under which the anther lies. A plant called *Orchido-funkia pallidiflora* belongs to the genus.

**CRYPTOCARYA.** A genus of *Lauraceae*, consisting of trees natives of the tropics of both hemispheres, and of Australia. The leaf buds are scaly. The flowers are hermaphrodite, with a somewhat funnel-shaped six-cleft perianth; stamens twelve in four rows, the nine outer ones fertile, the three inner sterile; the innermost row of the fertile stamens has stalked glands at each side of each stamen, and the

anthers of this row open outwardly, while those of the two outer rows open inwardly, in either case by two valves; the one-celled ovary is immersed in the calyx tube, which becomes succulent as the fruit ripens, concealing the latter, hence the name of the genus. *Brazilian Nutmegs* are the produce of *C. moschata*. [M. T. M.]

**CRYPTOCERAS.** A section of the funariaceous genus *Corydalis*, containing a few species from the warmer parts of temperate Asia. They have enlarged fusiform rootstocks, simple stems with two opposite leaves, which are ternate with imbricated segments, and very large flowers. [J. T. S.]

**CRYPTOCHILUS sanguinea.** A terrestrial orchid from the cooler parts of India, with leathery lanceolate leaves, and scapes bearing spikes of crimson tubular flowers. There is another species from the same country, the flowers of which are smaller and yellow.

**CRYPTOGAMS.** Many names have been applied to the vast class of plants comprehended under this name, as Asexual, or Flowerless Plants, Acrogens, Agamæ, Anandæ, Acotyledons, Cryptogams, Cryptophyta, Cellulares, Exembryonata, &c. Some of these have been given to them by authors collectively, while others have been appropriated to one of the two great sections into which Cryptogams are divisible. Of these we have chosen the term **CRYPTOGAMS** as liable to fewer objections than most others, and predicating little that is exposed in the present state of our knowledge to much contradiction. We have already stated the objections to which some are subject, as Asexual Plants, Acotyledons, Anandæ, and Cellulares; others will be mentioned hereafter. The great distinctive point of Cryptogams does not consist in the absence of decided male and female organs, nor in their minuteness, for in the greater part their presence has been ascertained beyond all doubt, and the analogous organs in phænogams often require the assistance of the lens to make out even their external form clearly. The main point is that the reproductive organs are not true seeds containing an embryo, but mere cells consisting of one or two membranes inclosing a granular matter. These bodies, whether called spores or sporidia, produce by germination a thread or mass of threads, a membrane, a cellular body, &c., as the case may be, which either at once gives rise to the fruit or to a plant producing fruit. Indeed the differences are so great that these spores seem rather to be relatives, or what is technically termed homologues, of pollen grains, than of true seeds.

The Cryptogams are divided into two great classes, **THALLOGENS** and **ACROGENS**, whose distinctive characters will be found under those heads. It is scarcely possible to give any general character of the whole except that which we have indicated above, as these two divisions are as distinct from each other as Cryptogams

themselves are from phænogams. Many of them indeed consist entirely of cells, but so do some more perfect plants, and vascular tissue exists in many Cryptogams. The greater part increase from the tips of the threads, but cell division takes place occasionally in other parts; while even in exogens, the main growth of the cells of which the wood and bark are composed is similar. Again, if they have no true pistils and anthers, they have their analogues, while in several an embryo is at length produced, and in *Saluginella* something even like cotyledons. Both the embryo and cotyledons are, however, aftergrowths, and not derived immediately from the spore. The consideration of the relations between the reproductive organs of phænogams and Cryptogams is one of the most interesting which is to be found in Botany, but it is also one of the most abstruse and difficult, and can be followed out only by those who have an intimate knowledge of the structure and functions in either branch of the vegetable kingdom. Such considerations would be wholly out of place in a work like the present. [M. J. D.]

**CRYPTOGLOTTIS serpyllifolia** is a little trailing moss-like orchid growing on trees in the Malayan archipelago. Its flowers are very minute. It is the same as the *Hexamera* of Brown, and notwithstanding its diminutive dimensions, is nearly related to the showy *Angraecum*.

**CRYPTOGRAMMA.** A small genus of polypodiaceous ferns of the group *Platylomeæ*. They are very closely related to our native *Allosorus*, with which they are indeed sometimes, and, perhaps rightly, united. The typical species of the present genus, *C. acrostichoides*, has, however, the spore-cases continued in lines along the course of the veins from the margin a short distance inwards, so as to be unmistakably oblong or linear-oblong, and hence has the distinguishing characteristic of the *Platylomeæ*; while in *Allosorus*, as now restricted, the sori are normally punctiform, and therefore polypodioid. They simulate the *Florida*, in consequence of the reflexed herbaceous margin resembling an indusium. The aspect of the plants is quite that of *Allosorus crispus*, being of dwarf and tufted habit, with dimorphous fronds, and having the fertile plannules formed like a siliole or short pod. There are three species, *C. acrostichoides*, found in Arctic America, *C. sitkensis*, found in Sitka, and *C. Brunoniana*, found in India. [T. M.]

**CRYPTOMERIA.** A lofty evergreen tree, forming a genus of *Conifera* of the tribe or suborder *Cupressinæ*. The leaves are shortly linear, falcate, rigid and acute, crowded but spreading. The flowers are monocious, the males in axillary catkins, the peltate scales bearing five anther-cells at their base. The fruits are in small terminal globular cones, with palmately-lobed imbricate scales, each one covering four to six winged seeds. *C. japonica*, the only species known, is a native of North China

and Japan, and being hardy enough to sustain our climate without injury, is now very generally planted in collections of Conifers. It is not, however, suited to heavy soil.

**CRYPTONEMATA.** Small cellular threads produced by cryptostomata.

**CRYPTONEMIAOCEÆ.** One of the largest natural orders amongst the rose-spored *Algae*, belonging to the section *Gongylopermeæ*, in which the inarticulate cartilaginous frond consists of a number of jointed threads compacted by gelatine. In the membranous species it is sometimes formed of many-sided cells, decreasing in size towards the surface. The capsules are immersed and are sometimes compound, and the spores are congregated without order. These arise either from several congregated fertile cells, which at length enlarge their endochrome, giving rise to a multitude of spores, or from a single cell, according as they are compound or simple; in the former case all trace of the original structure is frequently lost when the fruit is perfected. The genera and species are numerous, and occur in all climates. *Chondrus crispus* with several species of *Iridaea* and *Gigartina* belonging to this order, abound in gelatine, and in consequence are useful for many domestic purposes. [M. J. B.]

**CRYPTOPHYTES.** A synonym of cryptogams. [M. J. B.]

**CRYPTOPUS elata** (*Beclardia* of Rich.) is a handsome epiphytall orchid from the Isle of Bourbon. It has the habit of *Epidendrum elongatum*, the double gland and caudicle of an *Angraecum*, and flowers with deeply-lobed petals and lip; their colour is white dotted with purple.

**CRYPTOS.** In Greek compounds=concealed; thus *Cryptogama* are plants with concealed sexes.

**CRYPTOSANUS.** *Leochilus*.

**CRYPTOSEMA.** A name sometimes given to a West Australian bush of the pea family, also called *JANSONIA*: which see. [A. A. B.]

**CRYPTOSORUS.** A very appropriate name proposed for a few species of small-growing Ferns, having sunken punctiform nonindusiate sori, but which are not generally considered sufficiently distinct from *Polypodium*. [T. M.]

**CRYPTOSTEGIA.** A genus of twining shrubs, belonging to the natural order *Aclepiadaceæ*, and containing a single species from India and another from Madagascar. They have opposite leaves, and large reddish-white flowers in terminal cymes. The calyx consists of five lanceolate sepals; in the tube of the corolla there are five linear bipartite scales; the stamens are included, and have very short filaments inserted at the base of the tube, and the oval pollen masses are solitary and attached to the five glandular points

on the globose stigma. The large three-sided follicles are widely divaricate, with an incurved apex and comose seeds.

The plants of this genus abound in milky juice, which when exposed for a short time to the sun is converted into pure caoutchouc. [W. C.]

**CRYPTOSTOMATA.** Little circular nuclei found on the surface of some algae.

**CRYPTOSTYLIS.** A small genus of brown-flowered terrestrial orchids inhabiting New Holland, Java, and Ceylon. The main character consists in its having a great dorsal lip hollowed out at the base to receive the column. The abolished genus *Zosterostylis* is one of the species.

**CRYPTOTÆNIA.** A genus of *Umbelliferae*. The Honewort, *C. canadensis*, is the only species, and is one of a goodly number of plants common to North America and Japan. It is a smooth perennial erect herb, one to two feet high, having ternate stalked leaves with ovate coarsely-toothed leaflets, and numerous umbels of small white flowers, curiously disposed in an almost panicle manner, which is very unusual in the family. The fruit is linear-oblong, contracted at both sides, each of the carpels having five equal obtuse ribs, with an oil tube (vitta) in each furrow, and one under each rib. [A. A. B.]

**CRYPTOTHECA.** A genus of *Lythraceæ*, containing bog herbs or undershrubs from Japan with angular stems, opposite shortly stalked lanceolate or linear-lanceolate leaves, and axillary many-flowered peduncles. The calyx is funnel-shaped, four-cleft; corolla of four small petals or absent; stamens two, with roundish anthers; style lateral; capsule one-celled, irregularly circumscissile, inclosed in the calyx tube. [J. T. S.]

**CRYPTOTHECII.** A small group of mosses, represented by *Spiridens*.

**CRYSTALWORTS.** A name given by Lindley to the *Ricciaceæ*.

**CTENOMERIA.** A genus of slender twiners of the spurgewort family, found in South Africa. The slender cobwebby filaments of the male flowers, together with the pectinately-toothed calyx leaves of those of the females, serve to distinguish it from its allies. The wiry stems are furnished with distant nettle-like heart-shaped leaves, and the small green flowers are disposed in racemes which arise from opposite the leaves. [A. A. B.]

**CTENOPTERIS.** A name originally proposed as a sectional division of *Polypodium* by Blume, a Dutch botanist, and subsequently adopted as a genus, with various modifications by modern pteridologists. It is, however, synonymous with the true or typical species of *Polypodium*. [T. M.]

**CUBEBA.** A genus of *Piperaceæ*, the distinguishing features of which are, the dioecious flowers partially covered by sessile bracts and the fruits elevated on a

sort of stalk, formed from the contraction of the base of the fruit itself, so that they are not really but only apparently stalked. They are shrubs frequently of climbing habit, indigenous in the tropics of Asia and Africa. *C. officinalis*, a native of Java, furnishes the cubeb fruits of com-

*Cubeba canina*.

merce, which are like black pepper but stalked. They have an acrid hot aromatic taste, and are specially useful in diseases of the bladder and urinary passages. In large doses they give rise to symptoms of irritant poisoning. *C. canina* is also said to furnish some portion of the commercial cubeba. [M. T. M.]

**CUBEBS.** The fruits of various species of *Cubeba*, as *C. officinalis*, *C. canina*, and others.

**CUCHUNCHULLY** or **CUICHUNCHULL.** *Tonidium microphyllum*.

**CUCKOLD TREE.** *Acacia cornigera*.

**CUCKOO-FLOWER.** *Cardamine pratensis*; also *Lychnis Flos-cuculi*.

**CUCKOO-PINT.** *Arum maculatum*.

**CUCUBALUS.** A genus of *Caryophyllaceae*, of the tribe *Sileneae*, containing a single European herb which has been found in the Isle of Dogs, but doubtless introduced. It has trailing stems, opposite ovate leaves, and shortly stalked drooping whitish flowers in dichotomous cymes. The calyx is bell-shaped; the petals deeply cleft; stamens ten; styles three; fruit a globular berry, at first reddish, but black when ripe; seeds numerous. [J. T. S.]

**CUCULLATE.** When the apex or sides of anything are curved inwards, so as to resemble the point of a slipper, or a hood as in the lip of *Cypripedium* and *Calyptus*.

**CUCULLUS.** A hood or terminal hollow.

**CUCUMBER.** *Cucumis sativa*. —, **BITTER.** *Citrullus* or *Cucumis Colocynthis*, commonly called *Colocynth*. —, **INDIAN.** *Medeola virginica*. —, **ONE-SEEDED STAR.** An American name for *Sicyos*. —, **SINGLE-**

**SEEDED.** A common name for *Sicyos*. —, **SNAKE.** *Trichosanthes colubrina*; also *Cucumis sczeuensis*. —, **SPIRTING** or **SQUIRTING.** *Echium agreste*, formerly called *Momordica Elaterium*.

**CUCUMBER-ROOT.** An American name for *Medeola*.

**CUCUMBER-TREE.** An American name for *Magnolia acuminata* and *M. Fraseri*.

**CUCUMBERTS.** A name proposed for the *Cucurbitaceae*.

**CUCUMIS.** A genus of *Cucurbitaceae*, comprising a number of species, among which the most remarkable are the *Cucumber*, *C. sativus*, so well known as one of our most ancient table esculents, and the *Melon*, *C. Melo*, equally familiar to us as one of our most ancient and luscious fruits. Some of the species possess valuable medicinal properties. Nearly all are annuals and natives of the warmer parts of Asia, Africa, and America. It is worthy of note that the tender tops of all the edible species of *Cucurbitaceae*, boiled as greens or spinach, are even a more delicate vegetable than the fruit.

The *Cucumber*, *C. sativus*, is a tender annual, having rough trailing stems, with large angular leaves, and yellow male and female flowers borne in the axils of the leaf stalks. It is a native of Asia and Egypt, where it has been cultivated for more than 3,000 years. It is mentioned as one of the things for which the Israelites longed while in the wilderness, and complained to Moses (Numbers xi. 5). At a very early period it was grown by the Greeks and Romans, and according to Pliny, the Emperor Tiberius had Cucumbers at his table every day in the year. They were known in England in the time of Edward III. (1327), but during the wars of the Houses of York and Lancaster their cultivation was neglected, and the plant lost until the reign of Henry VIII., when it was again introduced. Since then it has gradually increased in public favour until it has now become of such importance as to be an object of rivalry with gardeners to produce fruit for the great and wealthy at all seasons. In summer such is the demand for this esculent that in order to obtain a sufficient supply, it is grown extensively in forcing frames, and in the counties near the metropolis, whole fields are devoted to cucumbers as a crop. Although cold and watery, and by some considered unwholesome, still the fruits are generally much esteemed as forming a most grateful salad when cut into very thin slices, and dressed with vinegar, &c. In a young state when small they are called *Gherkins*, and are in great request for preserving in vinegar, or for pickling with other vegetables. It is recorded that the village of Sandy in Bedfordshire has been known to furnish for the London market, 10,000 bushels for this purpose in one week! [W. B. B.]

The *Melon*, *C. Melo*, is the *Pepon* of Dioscorides, the *Melopepon* of Galen, and the *Melo* of Pliny. In Greece at the present

day it is named Peponia. In Italy in 1539, the names of Pepone, Melone, and Melone were applied to it. In Sardinia, where, it is remarked by De Candolle, Roman traditions are well preserved, it is called Meloni. From the Spaniards in the beginning of the sixteenth century, it received the name of Melon, which it retains in France, England, and with but slight modifications in other countries throughout Europe, where indeed the uniformity of name seems to indicate an introduction not very remote. De Candolle is of opinion that the species was originally confined to the valleys in the south of the Caucasus, and chiefly to the southern coasts of the Caspian. But its cultivation in the open air has long been extensively practised over a great part of Asia. It even appears to have been introduced into Italy early in the first century, if not before, as it is mentioned by Pliny, who died from suffocation caused by the great eruption of Vesuvius in A.D. 79. In his works he describes the modes by which melons were grown or forced, so as to be obtained for the Emperor Tiberius at all times of the year. Their cultivation, however, appears to have been very limited in Europe till within the last three centuries. According to M. Jacquin, *Monographie complète du Melon*, the Cantaloup variety derives its name from Cantaluppi, a seat belonging to the Pope, near Rome, where this sort, brought from Armenia by the missionaries, was first cultivated. He states further that it was received into France from Florence; that from France it passed into Spain, and thence into England, where, according to some authors, it has been cultivated since 1570; but the precise time of its introduction is uncertain. Probably the cultivation of Melons had been attempted much earlier. Till lately they were called in this country Musk Melons to distinguish them from water melons, which belong to a different species. Persia is noted for the excellence of its Melons, and the extensive scale on which their cultivation is carried on. Some nobles and wealthy individuals keep, it is said, from 10,000 to 20,000 pigeons, chiefly for manuring their melon beds, pigeons' dung being there considered the best manure for these plants. A collection of seeds of the best Persian varieties was sent in 1824 to the Horticultural Society by Sir Henry Willock, ambassador at the court of Persia; and some of the kinds when grown under particular treatment in this country proved excellent, but they are apt to degenerate. The melons of Bokhara are of the highest excellence, although in our climate they are liable to the same objection with regard to degeneration as those of Persia. Burnes in his *Travels* says 'The Melon is the choicest fruit of Bokhara. The Emperor Baber tells us that he shed tears over a melon of Turkistan which he cut up in India after his conquest: its flavour brought his native country and other dear associations to memory. There are two distinct species of Melons which the people class into hot and cold; the first ripens in

June, and is the common Musk or Scented Melon of India; the other ripens in July, and is the true Melon of Turkistan: in appearance it is not unlike a water melon, and comes to maturity after being seven months in the ground. It is much larger than the common sort and generally of an oval shape, exceeding two and three feet in circumference. Some are much larger, and those which ripen in the autumn have exceeded four feet. One has a notion that what is large cannot be delicate or high-flavoured; but no fruit can be more luscious than the Melon of Bokhara, nor do I believe their flavour will be credited by any one who has not tasted them. The Melons of India, Cabool, and even Persia, bear no comparison with them—not even the celebrated fruit of Ispahan itself. There are various kinds: the best is named Kocchu, and has a green and yellow-coloured skin; another is called Ak nubut, which means white sugar candy; it is yellow and exceedingly rich. The Winter Melon is of a dark green colour, called Kara knobuk, and said to surpass all the others. Bokhara appears to be the native country of the Melon, having a dry climate, sandy soil, and great facilities for irrigation.' (*Burnes' Travels in Bokhara*.)

Provided the soil is moist below, the Melon succeeds in all countries where the summer is sufficiently hot, even although the winters are cold, as is the case at Cabul, where severe winters are succeeded by very hot summers. There, Melons are produced in great abundance. Being an annual, its vegetation only commences naturally when the soil and air are warm; the fruit ripens in summer or before winter; and the plant then dies off before cold weather sets in. In the middle and southern states of America, Downing informs us, Melons are raised as field crops by market gardeners, the seeds being sown in the open air in May, and ripe fruit is obtained in August. In Australia likewise Melons are produced with the greatest ease in extraordinary abundance. There are many varieties of Melons, differing in size, form, and colour. Some are round or oblate, others oblong or oval; the surface of some is smooth, of others ribbed, netted, or warted. The flesh is either white, greenish, salmon-coloured, or red. The green-fleshed varieties are now generally preferred.

The Water Melon, *C. Citrullus*, is supposed to be of more ancient introduction to Europe than the foregoing. Rauwolf, in 1574, found it in abundance in the gardens of Tripoli, Rama, and Aleppo, under the name of Bathiera, the root of which word is from the Hebrew Abbatichim, one of the fruits of Egypt which the Jews regretted in the wilderness. It still forms chiefly the food and drink of the inhabitants of Egypt for several months in the year. It is very much cultivated in India, China, Cochín-China, Japan, the Indian archipelago, in America, and in short in most dry hot parts of the world, on account of its abundant refreshing juice, which, however, is not so rich and sugary as that

of the common Melon. It is not esteemed in this country, where it is rarely grown. [R. T.]

**UCURBITACEÆ. (Nandirobeæ, Cucurbita, the Cucumber and Gourd family.)** A natural order of polypetalous and gamopetalous calycifloral dicotyledons, characterising Lindley's cucurbitalliance. Succulent climbing plants with tendrils in place of stipules, alternate palmately-veined rough leaves, and staminate and pistillate flowers. Calyx adherent, its limb five-toothed, or obsolete. Petals four to five, usually united (gamopetalous), reticulated. Stamens generally five, distinct or combined; anthers long and wavy. Ovary one-celled, inferior, with three parietal placentas, which often send processes into the cavity so as to reach the centre, and there unite; stigmas thick. Fruit succulent, a pepo (gourd); seeds flat, without albumen; cotyledons of the embryo leafy. Natives chiefly of hot countries; they are found in India and South America, a few are found in the North of Europe and North America; some are also met with at the Cape of Good Hope and in Australia.

The plants of this order possess generally a certain amount of acridity. Many of them are powerful purgatives, such as the melon, cucumber, vegetable marrow, gourd, pumpkin and squash; while of others the fruits are edible when cultivated. The seeds are usually harmless. The pulp of the fruit of *Citrullus Colocynthis*, the colocynthis, or bitter apple, is the colocynthis of the shops; this is supposed to be the wild gourd of Scripture. *Ecballium purgans* or *agreste* (*Momordica Elaterium*) is called squirting cucumber on account of the elastic force with which its seeds are scattered; the deposit from the fluid of the fruit constitutes the powerful purgative called elaterium. *Cucumis sativus* is the common cucumber, *C. Melo* the melon, and *C. Citrullus*, the water-melon. *Cucurbita Pepo*, the gourd, is a scrambling plant, to which belong the vegetable marrows, which are edible, the orange gourds, which are bitter, the egg-gourds, giraumons, crooknecks, Turks caps, and warted gourds. *C. maxima*, the pumpkin, bears immense fruit; and *C. Melopepo*, the Squash, forms a bush about 3 ft. high, and may be had in the shops under the names of Pâtisson, Elektor's Cap, and Jerusalem Artichoke Gourd. The seeds of *Hodgsonia* are eaten in India. *Lagenaria vulgaris* supplies fruit, which after the pulp is removed is used for carrying water, under the name of bottle-gourd. The fruit of *Luffa Egyptiaca* is cut up when dry and used as a flesh brush, under the name of towel-gourd. *Sesquima edule* yields an edible fruit called chocho or chacha. The species of *Bryonia* are purgative. There are three divisions of this order: 1. *Nandirobeæ*, anthers not wavy, placentas adhering in the axis of the fruit, seeds numerous; 2. *Cucurbitææ*, anthers wavy, placentas and seeds as in the first; 3. *Sicyææ*, placentas not projecting into the cavity, seeds solitary from the top

of the cell. There are about seventy genera, and 340 species. *Bryonia*, *Citrullus*, *Momordica*, *Luffa*, *Cucumis*, *Cucurbita*, *Coccinia*, *Trichosanthes*, *Telavaria*, *Festilæa*, and *Sicyos* are examples. [J. H. B.]

**UCURBITA.** The typical genus of the *Cucurbitaceæ*, and composed of herbaceous mostly climbing plants, that are natives of hot countries in both hemispheres, chiefly within the tropics. A few are found in the north of Europe and North America, but India appears to be their head quarters. Those which are annuals readily submit to the climate of northern latitudes during summer. Although we best know the cucurbits by the use of the melon, cucumber, vegetable marrow and similar plants, yet it must be borne in mind that acrimony and a drastic tendency pervade many species, the fruits of some of which afford cathartics of remarkable power. Such being the predominant quality of the family it is well to be cautious in the use of even the best known species. (*Lindl. Veg. King. p. 313.*)

The Pomplon or Pumpkin Gourd, *C. Pepo*, of which there are many varieties, is a tender or half-hardy annual, a native of Astrachan, and is stated to have been cultivated in England since 1570. It has large rough heart-shaped five-lobed leaves, and hispid branching tendrilled stems, which in good soil will grow rapidly and cover a large space in the course of a season; the flowers are large deep yellow. The fruit is oblong egg-shaped, varying both in form and size, and is used for soups or stews, but more frequently in this country it is mixed with sliced apples, to which a little sugar and spice are added, and after being baked is eaten with butter under the name of pumpkin pie. Until 1818, according to London, this was the principal kind of gourd cultivated in British gardens—in those of the rich chiefly for ornament, and in those of the poor, in some parts of England, as a culinary vegetable.

The Egg-shaped or Succade Gourd, or Vegetable Marrow, *C. ovifera succada*, sometimes regarded as a variety of *C. Pepo*, is believed to have been originally brought from Persia, but the date of its introduction is not exactly known. It is one of the most valuable sorts of gourd for culinary purposes that we possess. The plant is similar in habit and appearance to the other kinds of trailing gourds; and the leaves are rough, middle-sized, and deeply-lobed. The fruit is of an uniform pale greenish yellow, of an elongated oval-shape, slightly ribbed and about nine inches long. It is used in every stage of its growth, and is peculiarly tender and sweet; when very young it is good if fried in batter, but it is in the intermediate or half-grown state that it deserves the name of Vegetable Marrow. It is then excellent when plain boiled and served with rich sauces. For many years this valuable esculent was only to be met with in the gardens of the wealthy, but it is now extensively cultivated, and during the latter part of sum-

mer and autumn it forms one of our common vegetables.

The Melon Pumpkin, *C. maxima*, is one of the largest examples of the gourd tribe. It is a native of the Levant, and is recorded to have been introduced in 1547. The stems are angular, rough and trailing, with large heart-shaped five-lobed tooth-letted rough leaves. The flowers are large bell-shaped deep-orange. The fruit is roundish, often flattened at top and bottom, slightly ribbed, of a pale buff or salmon colour, and thickly netted over its surface with narrow vermicular processes. When dressed it has a peculiar flavour not unpleasant to the taste, and forms an excellent substitute for carrots or turnips. It is the *Potiron* of the French, who use it largely in soups, as well as mashed in the manner of potatoes. In North America it is extensively cultivated as an article of food, and as it keeps well it affords a supply through a great part of the winter. The fruit often attains a large size. One grown at Luscombe in Devonshire is mentioned in the *Gardener's Magazine* (vii. 102), as having weighed 245 lbs. Another, grown at Lord Rodney's in 1834, weighed 212 lbs., and was 8 ft. round. Yellow, green, and grey varieties are cultivated.

Besides the gourds just noticed as being the sorts that have been longest cultivated and best known in this country, there are many other sorts well deserving of attention. Among these we would particularly mention the Custard Marrow Squash, and the improved Custard Marrow or Bush Squash, both of which are prolific and highly esteemed for their superior excellence, as well as for the peculiar form of their fruit, which for culinary purposes are remarkably handsome and in great request. Many kinds of gourds are also exceedingly ornamental. [W. B. J.]

**CUDBEAR.** A name given in Scotland to a crimson dye prepared from *Lecanora tartarea* and some other lichens, by treating them with alkaline substances. The collection of the lichen formerly employed a great number of hands, but it is now much neglected. A person so employed could earn fourteen shillings a week, the lichen being sold at about three halfpence a pound. It is now principally procured from Sweden and Norway, the manufacture being chiefly in the hands of the English. The name was derived from Dr. Cuthbert Gordon who first introduced the manufacture in Glasgow. [M. J. B.]

**CUDRANIA.** Climbing spiny shrubs, belonging to the *Artocarpaceæ*; they are natives of the Moluccas, Philippines, and India, and have entire dioecious flowers, the females in globose or oblong heads, each with a four-leaved perianth, and a pendulous ovule. [M. T. M.]

**CUDWEED.** The common name for *Gnaphalium*.

**CUICHUNCHULLI.** *Ionidium microphyllum*,

**CUITLAUZINA.** *Odontoglossum*.

**CUJUMARY BEANS.** The fruits of *Ayendron Cujumary*.

**CULANTRILLO.** The Chilian name for *Tetilla*, an astringent plant.

**CULCASIA.** A little known genus of *Araceæ*, comprising a tropical African species, with entire stalked leaves, and a brownish spathe enclosing a spadix bearing male and female flowers, and intermediate rudimentary organs. Ovaries crowded, each with one ovule. [M. T. M.]

**CULCITA.** *Dicksonia Culcita*. The name has sometimes been used generically to separate this species from the rest of the genus *Dicksonia*. [T. M.]

**CULCITIUM.** A genus of *Compositæ*, composed of woolly herbs or small bushes found in the Andes of Peru and Columbia near the snow limit at an elevation of 14,000 or 15,000 feet above the level of the sea. The name derived from *Culcita*, a cushion, is given, because all parts of the plants, except the upper surface of the leaves of a few, are covered with dense white or rusty coloured woolly hairs, which serve as beds for those travellers who may be forced to spend the night in the open air at this great elevation. The manner of making the bed is, by first amassing a quantity of the plants, and after taking the soft woolly pappus from the flowers, laying the branches, with the leaves attached, on the ground. On this first layer the soft warm pappus hairs are scattered, then a third layer is placed of leaves only, and, lastly, another layer of pappus hairs. On this couch the traveller reposes after the toils of the day without fear of frozen limbs. The genus *Espeletia* also belongs to this family, and growing on the high Andes, bears much resemblance to this in the woolly clothing of the leaves and stems, but the present is easily distinguished from it, the forests being all tubular, while in *Espeletia* there is an outer row of strap-shaped forets in the flower-head. Their nearest relationship is to the groundseels, *Senecio*, from which they may be at once recognised by their appearance. About a dozen species are known, some attaining a height of five or six feet, and having lance-shaped root leaves from six inches to a foot in length clasping the stem with their sheathing bases; these are sometimes called Lion's ear. [A. A. B.]

**CULEN.** A Chilian name for *Psoralea glandulosa*.

**CULILAWAN BARK.** The bark of *Cinnamomum Outilawan*, or Clove Bark.

**CULLUMIA.** A genus of little Cape bushes belonging to the composite family, and distinguished from its allies by the achenes being destitute of pappus, as well as by the curiously spinous margins of the leaves. These are seldom more than an inch long (generally much shorter), oblong in form, sessile, and often closely pressed

to the stem. In a great many the margins are bordered with a single row of slender bristles about an eighth of an inch in length and in a few there is a double row of these bristles, one set pointing upwards, the other directed downwards. In all cases the leaves are terminated by a bristle. The yellow flower-heads are single on the ends of the branches, and half an inch or more in diameter. The scales of the involucre, in many rows, are furnished with bristles like the leaves. The florets of the outer row are strap-shaped and barren, of the inner tubular and fertile. About twenty species are enumerated. [A. A. B.]

**CULM.** The straw of corn; a kind of hollow stem.

**CULMIFEROUS.** Producing culms.

**CULVER'S ROOT** or **CULVER'S PHYSIC.** American names for *Veronica virginica*.

**CUMIN** or **CUMMIN.** *Cuminum Cyminum*. —, **BLACK.** The pungent seeds of *Nigella sativa*. —, **SWEET.** The Anise, *Pimpinella Anisum*. —, **WILD.** *Lagocnemis*.

**CUMIN CORNU.** (Fr.) *Hypecoum pycnanthum*. — **NOIR.** *Nigella sativa*.

**CUMINUM.** Fennel-like plants, belonging to the *Umbelliferae*, and botanically characterised by the presence of both general and partial involucre, the latter one-sided; by the calyx having five lance-shaped teeth; and by the elongated fruits, slightly contracted at the side, and each half provided with five thread-like ridges, and four intermediate ones more prominent and slightly prickly, beneath each of which there is an oil channel or vitla. The cumin seeds or fruits are the produce of *C. Cyminum*. They are much like those of caraway, but larger and of lighter colour, and with nine in place of five ridges on each half of the fruit. They are but little used, as caraways are more agreeable and more efficacious. The seeds of cumin smoked were considered by the ancients to produce pallor of the countenance. [M. T. M.]

**CUMINGIA.** A genus of *Liliaceae*, consisting of bulbous Chilian herbs, with linear-lanceolate nervose leaves, and branched scapes bearing panicles of nodding blue flowers. The perianth is bell-shaped, the tube adhering to the base of the ovary, the limb six-parted with spreading segments. The six stamens are inserted in the tube, and have short compressed filaments; the ovary is three-celled with many ovules, the style subulate and the stigma simple. The genus is near *Conanthera*, but differs in having a less divided perianth, in the same way as *Hyacinthus* differs from *Scilla*. *C. campanulata* is a very interesting plant, with linear-channelled leaves, and a stem from a span to a foot high, bearing a racemose panicle at top, the flowers violet, paler in the throat around which they are spotted with blackish purple. [T. M.]

**CUNEATE, CUNEIFORM.** Wedge-shaped. Inversely triangular, with rounded angles.

**CUNCULATE.** Traversed by a long passage, open at one end, as the peduncle of *Tropaeolum*.

**CUNILA.** A genus of *Labiatae*, containing several species of perennial herbs or undershrubs, natives of N. America. They have small white or purplish flowers, in corymbed cymes or close clusters. The calyx is ovate-tubular, equally five toothed, and hairy in the throat; the corolla is two-lipped, with the upper lip erect, flattish, mostly notched, and the lower somewhat equally three-cleft; the two inferior stamens, which alone are fertile, are erect, exerted, and distant, and there are no traces of the superior stamens; the apex of the style is shortly bifid with subulate lobes. The nucule is smooth. [W. C.]

**CUNIX.** The separable space which intervenes between the wood and bark of exogens; an obsolete word.

**CUNNINGHAMIA.** A lofty evergreen tree, forming a genus of *Coniferae* of the suborder or tribe *Abietinae*. The linear falcate or lanceolate stiffly-pointed leaves are nearly those of the American *Araucaria*, but of a brighter green and less rigid. In the flowers and cones, the genus is nearly related to *Pinus*, but there are three or four anther-cells instead of two to each scale of the male catkins, and three instead of two ovules or seeds to each scale of the females. *C. sinensis*, the only species known, is a native of South China, and too tender for our climate without protection; but it is occasionally to be seen in our conservatories, where, from the elegance of its habit, it is a welcome inmate when there is room for its development.

**CUNONIA.** A genus of *Cunoniaceae*, consisting of a small tree from the Cape of Good Hope, where it is called Rood Elze by the Dutch colonists. It has reddish twigs, and opposite pinnate leaves with oblong coriaceous serrated leaflets, and ovate caducous stipules. The dense racemes of small white flowers are axillary and opposite, with the pedicels fascicled; calyx five-parted, deciduous; corolla of five oblong petals; stamens ten; ovary free, with two diverging styles; capsule conical, two-celled, separable into two many-celled carpels. [J. T. S.]

**CUNONIACEAE.** (*Ochranthaceae*, *Cunoniads*.) A family of dicotyledons, closely allied to *Saxifragaceae*, and very generally considered as a tribe only of that family, differing more in their habit than in the structure of their flowers or fruit. They are shrubs or trees with opposite leaves, simple or compound, and have stipules between the leaf-stalks. The calyx is half-superior or nearly inferior, the petals and stamens perigynous, the latter definite or more rarely indefinite. The ovary is two-celled, with two or more ovules in each cell; the styles usually distinct; the fruit

capsular or indehiscent. They are natives chiefly of tropical regions or of the southern hemisphere, and especially of Australia. There are above a hundred species, distributed into about twenty genera, among which may be cited as the most generally known, *Weinmannia*, *Callicoma*, *Acrophyl- lum*, *Ceratopetalum*, *Cunonia*, *Caldcluvia*, *Belangeria*, &c.
